ENCYCLOPÆDIA BRITANNICA.

NA, Juan de, one of the Italianizing Spanish poets of the 15th century, was born at Cordova about We are informed by Romero, to whom we are d for almost all we know about his life, that he had l the age of twenty-three before he began to give to "the sweet labour of good learning," pursuing a course of study at Salamanca and afterwards at It was at the latter city that he first became ted with the writings of Dante and Petrarch, which rds so powerfully influenced his own style. Having l to Spain, he became a "ventriquatro," or magis f his native town, and was received as a poet with vour at the court of John II., being made Latin secre the king and historiographer of Castile. He died y, in consequence of a fall from his mule, in 1456, elaguna, where the marquis of Santillana, his friend tron, erected his monument and wrote his epitaph. a's principal work, *El Laberinto* ("The Labyrinth"), nes called *Las Trescientas* ("The Three Hundred") he original number of its stanzas, is a didactic y on the duties and destinies of man, obviously con l on the lines of the *Divina Commedia* of Dante. et, while wandering in a wood and exposed to the of various beasts of prey, is met by Providence in ise of a beautiful woman, who offers to guide him hrough the dangers which surround him, and at the me to explain- "as far as they may be grasped by understanding" the dark mysteries of life that upon his spirit. He is then led to the spherical of the five zones, where he sees the three wheels of , the past, the future, and the present, and the men ng to each, arranged in the seven circles of planetary re. Opportunity i. thus afforded for a vast quan- mythological and historical portraiture: the best s are those of the poet's own contemporaries, but rk in general is much disfigured with all sorts of y, and hardly ever attains to mediocrity as a poem. *laberinto* was first printed at Seville in 1496; Nunez anchez accompanied it with commentaries in 1499 82 respectively; and it is still regarded with a good reverence by the Spaniards as the "magnum opus" r "Ennius." De Mena was the author of a number or poems or "vers de société," written merely for court circles, and having neither general interest nor manent value, most of them are to be found in *Cancionero General*. He also wrote a poem entitled *Coronation*, the subject being the "crowning" of marquis of Santillana by the Muses and the Virtues Mount Parnassus. Finally, his *Siete Pecados Mor* ("Seven Deadly Sins") is a dull allegory on the antago between reason and the will of man. Complete edit of the poems of De Mena appeared in 1528, 1801, 1840.

MENAGE, Gilles (1613–1692), described by Bayl "one of the most learned men of his time, and the V of the 17th century, was the son of Guillaume Mén king's advocate at Angers, and was born in that cit August 15, 1613. A tenacious memory and an e developed enthusiasm for learning carried him spee through his literary and professional studies, and we of him practising at the bar at Angers as early as 1 In the same year he pleaded several causes before parlement of Paris, and soon afterwards he attended "Grand Tours" at Poitiers, but after having been aside by a severe illness he abandoned the legal profe and declared his intention of entering the church. succeeded in obtaining some sinecure benefices, and l for some years in the household of Cardinal De Retz (only coadjutor to the archbishop of Paris), where he ample leisure for his favourite literary pursuits. S time after 1648 he withdrew to a house of his own n cloister of Notre Dame, where his remarkable conversati powers enabled him to gather round him on Wedne evenings those much frequented literary assemblies w he called "Mercuriales." His learning procured for admission to the Della Crusean Academy of Florence, his irrepressible tendency to caustic sarcasm led to remorseless exclusion from the French Academy. He at Paris on July 23, 1692. Of the voluminous w of Menage (fully enumerated in the *Dictionnaire* Chauffepie) the following may be mentioned: *Ori de la Langue Française* (1650; greatly enlarged in 16 *Diogenes Laertius Græce et Latine, cum Commentario* (1 and again much improved in 1692); *Poemata La Gallica, Græca, et Italica* (1656, 8th ed., 1687). *Or della Lingua Italiana* (1669); and *Anti-Baillet* (1

καμάζειν) is ill suited even to choral metre. The Old Comedy rked by men of real genius, who "were indeed giants, while a of Menander's day only showed how strong and thorough h culture which in art and literature outlived the decadence nation."[1]

ll, we have, as collected by Meineke, 1015 fragments of ler, of which 515 can be referred to known plays, the of those quoted from amounting to ninety, and including entian *Andria*, *Adelphi*, *Eunuchus*, *Heautontimorumenos* fragments contain about 1650 verses or parts of verses, ng a considerable number of words quoted expressly as from ler by the old lexicographers. Besides all these there are er than 758 monostich verses separately preserved in MSS., some of these are met with in the other and longer frag-

Many of the fragments are obscure, some corrupt, and they en a fertile field for critical acumen from the time of Bentley. frequently we come upon the shrewd or original remark of erver. Thus (frag. 7) "A poor man has no relation, for no knowledges him, lest he should beg." Frag. 115: "Every that takes place is brought about by law, necessity, or " 237: "The gods do not give men through any human (prayer or sacrifices); if they did, the human would have ower than the divine." 270: "Poverty is the most costly of all evils, any friend can do it by merely putting his hand pocket." 397, "A poor man who lives in a large town needs t more wretched than he need, for he cannot help comparing n own the luxurious lives of the rich." 476, "No man s the extent of a sin when he commits it; it is afterwards e sees it." 560, "A man is convinced not so much by what as by the manner of saying it." 474, "There is one thing at hides vulgarity, villainy, and every other fault—wealth thing but that is carped at and criticized." 517: "People ve no merit of their own generally boast of their birth and ncestors. But every living man has some, or he would a living man." 578, "Wealth acts on a man as wind does on it often forces him out of his proper course." 663: "Many g lady says a great deal in her own favour by saying nothing." 688, "A man who abuses his own father is practising emy against the gods." In fact, Menander is characteristic sententious writer, like Euripides, with whom in the general f his writings, though not of course in his somewhat loose egular versification, he is sometimes compared. (F. A. P.)

ENCIUS, the Latinized form of Mâng tsze, "Mr ," or "Mâng the philosopher," a name in China only l as a moral teacher to that of Confucius. His statue irit-tablet (as the case may be) has occupied, in the es of the sage, since our 11th century, a place among four assessors"; and since 1530 A.D. his title has "the philosopher Mâng, sage of the second degree."

e Mângs or Mâng sung had been in the time of Con- s one of the three great clans of Lu (all descended the marquis Hwan, 711–694 B.C.), which he had en- ured to curb. Their power had subsequently been n, and the branch to which Mencius belonged had d in Tsâu, a small adjacent principality, the name ich still remains in Tsau hien, a district of Yenchâu tung. A magnificent temple to Mencius is the chief tion of the district city. The present writer visited 1873, and was struck by a large marble statue of him courtyard in front. It shows much artistic skill, and the impression of a man strong in body and mind, ghtful and fearless. His lineal representative lives e city, and thousands of Mangs are to be found in eighbourhood.

e dates of some of the principal events in Mencius's re fixed by a combination of evidence, and his death erred by common consent to the year 289 B.C. He had to a great age, some say to his eighty fourth year, ng his birth in 372 B.C., and others to his ninety th, placing it in 385. All that we are told of his r is that he died in the third year of the child, who hus left to the care of his mother. She was a lady perior character, and well discharged her trust. Her es and dealings with her son were celebrated by a writer in the first century before our era, and for two sand years she has been the model mother of China.

We have no accounts of Mencius for many years his boyhood, and he is more than forty years old w comes before us as a public character. He must hav much time in study, investigating the questions whi rite as to the fundamental principles of moral and and brooding over the condition of the country. T tory, the poetry, the institutions, and the great men past had received his careful attention. He intimat he had been in communication with men who ha disciples of Confucius. That sage had become to l duct of mortal men, the object of his untiring admi and in the doctrines which he had taught Mencius nized the truth for want of an appreciation of wh bonds of order all round him were being relaxed, a kingdom hastening to a general anarchy.

When he first comes forth from Tsau, he is accom by several eminent disciples. He had probably n Confucius to become the master of a school, a couraging the resort to it of inquiring minds t might resolve their doubts and unfold to them th methods of government. One of his sayings is would be a greater delight to the superior man to youth of brightest promise around him and to te train them than to enjoy the revenues of the ki His intercourse with his followers was not contin that of Confucius had been with the members selected circle, and, while he maintained his dignity them, he was not able to secure from them th homage and reverent admiration.

More than a century had elapsed since the d Confucius, and during that period the feudal king Châu had been showing more and more of th of dissolution, and portentous crimes that threate upset all social order were widely disseminated sentiment of loyalty to the dynasty had disap Several of the marquises and other feudal princes o times had usurped the title of king. The smaller s been absorbed by the larger ones, or reduced to a helpless dependence on them. Tsin, after greatly ing its territory, had broken up into three powerful dom, each about as large as England. Meanwhi the nation nominally one, and with the tradition thousand years affirming its essential unity, but divided into seven monarchies, each seeking to sub others under itself. The consequences were contin fare and chronic misery.

In Confucius's time we meet with recluses w withdrawn in disgust from the world, and it turne these had now given place to a class of men wh forth from their retirements provided with arts of chemes of policy which they recommended to the ruling chiefs, ever ready to change their allegiance were moved by whim or interest. Mencius was one about two of them. "Are they not really great men them be angry, and all the princes are afraid. L live quietly, and the flames of trouble are everywh extinguished." He looked on them as little no delighted to proclaim his ideal of the great man language as the following:

"To dwell in love, the wide house of the world to propriety, the correct seat of the world, and to walk in right the great path of the world; when he obtains his desire to practise his principles for the good of the people, and w desires to deny himself to practise them alone; to be a power of riches and honours to make himself poor, of pov mean condition to make him swerve from the right, and of p force to make him bend—these characteristics constitute t man."

Most vivid are the pictures which Mencius gives condition of the people in consequence of the wa states. "The royal ordinances were violated; th

[1] Mahaffy, *Ibid.*, p. 490.

ere oppressed, the supplies of food and drink
way like water.' It is not wonderful that, when
ndations of government were thus overthrown,
ons should have arisen that threatened to over
hat he considered to be the foundation of truth
social order. "A shrill-tongued barbarian from
h,' as Mencius called him, proclaimed the dissolu
anks, and advocated a return to the primitive
y.

"When Adam delved and Eve span,

his followers maintained that learning was
y, and statesmanship craft and oppression, that
nd peasant should be on the same level, and every
everything for himself. Another, called Yang chu,
he difference between virtue and vice, glory and
The tyrants of the past, he said, were now but so
tten bones, and the heroes and sages were no more.
he same with all at death, after that there was but
putridity and rottenness. The conclusion of the
natter therefore was—"Let us eat and drink; let
ty the ear and eye, get servants and maidens,
music, wine, when the day is insufficient, carry it
gh the night. Each one for himself." Against a
research, of a very different stamp, Mencius felt
indignation. This was Mo Ti, who found the
f all the evils of the time and of all time in the
mutual love. He taught, therefore, that men
love others as themselves; princes, the states of
nces as much as their own, children, the parents
s as much as their own. Mo, in his gropings, had
l of a noble principle, but he did not apprehend
rectly nor set it forth with discrimination. To
losopher the doctrine appeared contrary to the
an orthodoxy about the five relations of society,
attacked it without mercy and with an equal
n of thought. "Yang's principle," he said, "is
ne for himself,' which does not acknowledge the
t the sovereign. Mo's is 'to love all equally,'
oes not acknowledge the peculiar affection due to
But to acknowledge neither king nor father is
n the state of a beast. The way of benevolence
nteousness is stopped up."

this seething ocean of lawlessness, wickedness,
, and misery Mencius looked out from the quiet of
od, and his spirit was stirred within him to attempt
ne of the people from the misrule and error. It
e that he would prove the instrument for this pur

"If Heaven," he said, "wishes that the kingdom
enjoy tranquillity and good order, who is there
me to bring it about?" He formed his plan, and
ed to put it in execution. He would go about
the different kings till he should find one among
ho would follow his counsels and commit to him the
dminis tration of his government. That obtained,
not doubt that in a few years there would be a
n so strong and so good that all rulers would
ledge its superiority, and the people hasten from all
s to crown its sovereign as monarch of the whole of
This plan was much the same as that of Confucius
en, but, with the bolder character that belonged to
encius took in one respect a position from which
aster" would have shrunk. The former was always
o Châu, and thought he could save the country by
mation, the latter saw the day of Chau was
d the time was come for a revolution. Mencius's
as the more correct, but he was not wiser
e sage in forecasting for the future. They could
nly of a reformed dynasty or of a changed dynasty,
according to the model principles of a feudal com-
n, which they described in glowing language. They

desired a repetition of the golden age in the remote
but soon after Mencius disappeared from the stage
there came the sovereign of Chin, and solved the q
with fire and sword, introducing the despotic empire
has since prevailed.

An inquiry here occurs: "How, in the execution
plan, was Mencius, a scholar, without wealth or stat
find admission to the courts of lawless and unprin
kings, and acquire the influence over them wh
expected?" It can only be met by our bearing in
the position accorded from the earliest times in Ch
men of virtue and ability. The same written ch
denotes both scholar and officers. They are at the
the social scale, the first of the four classes into wh
population has always been divided. This appreciat
learning or culture has exercised a most powerful in
over the government under both conditions of its
ence, and out of it grew the system, which was org
and consolidated more than a thousand years ago, of
literary merit the passport to official employment
ancient doctrine was that the scholar's privilege wa
Heaven as much as the sovereign's right, the
system is a device of the despotic rule to put it
Heaven's place, and have the making of the schola
own hands. The feeling and conviction out of whi
system grew prevailed in the time of Mencius
dynasties that had successively ruled over the kingd
owed their establishment not more to the military go
their founder, than to the wisdom and organizing
of the learned men, the statesmen, who were their
friends and trusted counsellors. Why should
become to one of the princes of his day what I Y
been to Thang, and Thâi kung Wang to King Wa
the duke of Chau to Wû and Ch'ang? But, though M
might be the equal of any of those worthies, he kne
prince like Thang and the others, of noble aim an
who would welcome and adopt his lessons. In his
ness he overlooked this condition of success for his
prise. He might meet with such a ruler as he loo
or he might reform a bad one, and make him the co
that he required. On the strength of these petadve
and attended by several of his disciples, Mencius w
more than twenty years from one court to another,
baffled, and always ready to try again. He was r
with great respect by kings and princes. He
not enter into the service of any of them, but h
ionally accepted honorary offices of distinction; and
not scruple to receive large gifts which enabled him
and move about as a man of wealth. In deliver
message he was as fearless and outspoken as John
He lectured great men, and ridiculed them. He u
the ways of the old sage kings, and pointed out th
to universal sway; but it was all in vain. He could
any one to honourable action. He confronted here

We have to think of him, according to tradition,
the last twenty years of his life in the congenial
of his disciples, discoursing to them, and giving the
ng touches to the record of his conversations and
ns, which were afterwards edited by them, and con
his works. Living, he may have been a failure,
yet speaking in them, he has been a great power
the ever-multiplying millions of his countrymen.
will any thinker of the West refer to them without
st and benefit. Mencius was not so oracular, not
contained, as Confucius; but his teachings have a
y and sparkle of which we never weary, and which
heir own.

will now attempt to indicate briefly the more important
les which our philosopher thought would have been effectual
merate his country, and make an end of misery and heresy
its borders.

first as to his views on government and the work to be
y rulers for their subjects. Mencius held with Confucius
was a doctrine which had descended to them both from the
st antiquity that royal government is an institution of God
ient sovereign had said that "Heaven, having produced the
appointed for them rulers, and appointed for them teachers
ould be assisting to God. Our philosopher, adopting this
e, was led by the manifest incompetency of all the rulers of
e to ask how it could be known on what individual the
tment of Heaven had fallen or ought to fall, and he concluded
is could be ascertained only from his personal character and
duct of affairs. The people must find out the will of Heaven
ho should be their ruler for themselves. There was another
ng which delighted Mencius. "Heaven sees as the people
eaven hears as the people hear." He taught accordingly
hole government is from God, the governors are from the
, *vox populi vox Dei*.

laim then of a "divine right" should be allowed to a sovereign
re not exercising a rule for the good of the people. "The
are the most important element in a nation; the altars to
its of the land and grain are the second, the sovereign is
htest." Mencius was not afraid to follow this utterance to
sequences. The monarch whose rule is injurious to the
and who is deaf to remonstrance and counsel, should be
ed. In such a case "killing is no murder."

who is to remove the sovereign that thus ought to be removed?
is had three answers to this difficult question. First, he
have the members of the royal house perform the task. Let
lisown their unworthy head, and appoint some better man
al of their number in his room. If they could not or would
this, he thought, secondly, that any high minister, though
ied to the royal house, might take summary measures with
vereign, assuming that he acted purely with a view to the
weal. His third and grand device was what he called "the
er of Heaven." When the sovereign had become a pest
l of a blessing, he believed that Heaven would raise up some
r the help of the people, some one who should so conduct
f in his original subordinate position as to draw all eyes and
to himself. Let him then raise the standard not of rebel-
t of righteousness, and he could not help attaining to the
t dignity. Mencius hoped to find one among the rulers
day who might be made into such a minister, and he
lled one and another to adopt measures with that object.
in fact counselling rebellion, but he held that the house of
ad forfeited its title to the throne.

t now were the attributes which Mencius considered necessary
stitute a good government according to his ideal of it? It
be animated by a spirit of benevolence, and ever pursue a
of righteousness. Its aims must be, first, to make the people
f, and next, to educate them. No one was fit to occupy the
who could be happy while any of the people were miserable,
elighted in war, who could indulge in palaces and parks
the poorest did not in a measure share with him. Game
eceived his emphatic condemnation. Taxes should be light,
l the regulations for agriculture and commerce of a character
note and encourage them. The rules which he suggested to
those objects had reference to the existing condition of his
y, but they are susceptible of wide application. They carry
n schemes of drainage and irrigation for land, and of free
commerce. But it must be, he contended, that a sufficient
and certain livelihood be secured for all the people. Without
their minds would be unsettled and they would proceed to
form of wild license. They would break the laws, and the
would punish them—punish those whom his neglect of his
duties had plunged into poverty, of which crime was the conse
He would be, not their ruler, but their "trapper."

Supposing the people to be made well off, Mencius taught
education should be provided for them all. He gave the m
of Thang a programme of four kinds of educational institu
which he wished him to establish in his state—in the villa
the towns, for the poor as well as the rich, so that none m
remorant of their duties in the various relations of society
after all, unless the people could get food and clothing b
labour, he had not much faith in the power of education to
them virtuous. Give him, however, a government fulfilli
conditions that he laid down, and he was confident there
soon be a people, all contented, all virtuous. And he saw
to prevent the realization of such a government. Any ruler
become, *if he would*, "the minister of Heaven," who was hi
and the influence of his example and administration would
powerful. The people would flock to him as their priest, a
him to do justice on the foes of truth and happiness. Pu
grains would be abundant as water and fire, and the mult
well clothed and well principled, would sit under the s
their mulberry trees, and hail the ruler "King by the g
Heaven."

Secondly, as to Mencius' view about human nature. H
viction of the goodness of that encouraged him to hope fo
grand results from good government, and his direction to
object gives his principal title to a place among philos
thinkers.

Opinions were much divided about it among his contemp
Some held that the nature of man is neither good nor bad,
be made to do good and also to do evil. Others held t
nature of some men is good, and that of others bad; that m
the best of men sometimes have bad sons, and the worst
good sons. It was also maintained that the nature of man
and whatever good appears in it is the result of cultivatio
opposition to all these views Mencius contended that the n
man is good. "Water," he said, "will flow indifferently
east or west; but will it flow indifferently up or down
tendency of man's nature to goodness is like the tendency
to flow downward. By striking water you may make it le
your forehead, and by damming and leading it you may
go up a hill. But such movements are not according to the
of water, it is the force applied which causes them. Wh
do what is not good, their nature has been dealt with
way."

Mencius had no stronger language than this—as indeed
be difficult to find any stronger, to declare his belief of the g
of human nature. With various, but equally felicitous, illu
he replied to his different opponents. Sometimes he may
express himself too strongly, but an attentive study of his
how that he is speaking of our nature in its ideal, and n
actually is, as we may ascertain, by an analysis of it, tha
intended to be, and not as it has been made to become.
his doctrine of human nature is hardly to be distinguish
that of Bishop Butler, while the Christian prelate is left far
as the charm of style is concerned.

Our author insists on the constituents of human nature, e
especially on the principle of benevolence, righteousness, pr
and wisdom or knowledge the last including the judg
conscience. "These," said he, "are not infused into
without. Men have these principles just as they have th
limbs." But man has also instincts and appetites which se
own gratification without reference to righteousness or an
control. He met this difficulty by contending that human
is a constitution, in which the higher principles are des
rule the lower. "Some constituents of it are noble and
ignoble, some great and some small. The great must
injured for the small, not the noble for the ignoble."

One of his most vigorous vindications of his doctrine
following. "For the mouth to desire flavours, the eye
the ear sounds, and the four limbs ease and rest belong t
nature. An individual's lot may restrict him from the enjo
of them, and in such a case the superior man will not s
nature demands that pleasure, and I *will get it*. On th
hand, there are love between father and son, righteousness
ruler and minister, the rules of ceremony between host an
and knowledge seen in recognizing the able and virtuous,
the sage's fulfilling the heavenly course—these are appoin
Heaven. But they also belong to our nature and the
man will not say, The circumstances of my lot require
them." In his preliminary dissertation to the 7th edition
encyclopedia, Sir James Mackintosh has said that in his
on human nature Butler taught to the more worthy of th
of discovery than any in the whole department of inqui

e an acquainted; if we ought not to except the first steps
ecian philosophers toward a theory of moral. Menemus
or to Zeno, the one of those philosophers to whom Butler
adamity, and it does not appear that he had left anything
n of them to discover.

he proceeded from his ideal of human nature to account
phenomena of conduct so different from what they ought
cording to that ideal, he was necessarily less successful
zzled him and they made him indignant and angry. "There
g good," he said "that a man cannot do, he only does
t." But why does he not do it? Against the stubborn

NDELSSOHN, FELIX (1809–1847). Jakob Ludwig
Mendelssohn Bartholdy, one of the greatest com-
of this century, was the grandson of Moses Men-
se noticed below, and was born in Hamburg on
ary 3, 1809.

onsequence of the troubles caused by the French
tion of Hamburg, Abraham Mendelssohn, his father,
ed in 1811 to Berlin, where his grandmother,
t, then in the twenty fifth year of her widowhood,
d the whole family into her house, No. 7 Neue
nade. Here the little Felix and his sister Fanny
d their first instruction in music from their mother,
whose care they progressed so rapidly that the
her exceptional character of their talent soon
unmistakably apparent. Their next teacher was
ie Bigot, who, during the temporary residence of the
in Paris in 1816, gave them some valuable instruc
On their return to Berlin they took lessons in
glass and composition from Zelter, in pianoforte-
g from Ludwig Berger, and in violin playing from
Henning, the care of their general education being
trusted to the father of the novelist Paul Heyse.

Felix first played in public on the 24th of Oc
1818, taking the pianoforte part in a trio by Woelffl.
April 11, 1819, he entered the Berlin Singakademie
alto, and in the following year began to compose
extraordinary rapidity. His earliest dated work is a ca
In ruhrend feierlichen Tonen, completed on Januar
1820. During that year alone he produced nearly
movements, including songs, pianoforte sonatas, a
for pianoforte, violin, and violoncello, a sonata for
and pianoforte, pieces for the organ, and even a
dramatic piece in three scenes. In 1821 he wrot
symphonies for stringed instruments, each in three
ments, motetts for four voices; an opera, in on
called *Soldatenliebschaft*; another, called *Die beiden*
gegen; part of a third, called *Die wandernde Comedi*
and an immense quantity of other music of different
some of which, thought worthy of publication b
editors of his posthumous works, now stands befo
world in evidence of the precocity of his genius.
original autograph copies of these early productio
now preserved in the Berlin Library, where they for
of a collection which fills forty-four large volum
written with infinite neatness, and for the most
carefully dated a sufficient proof that the meth
habits which distinguished his later life were form
early childhood.

In 1821 Mendelssohn paid his first visit to Goethe
whom he spent sixteen days at Weimar, in company
Zelter. From this year also dates his first acquai
with Weber, who was then in Berlin superintendi
production of *Der Freischutz*; and from the summ
1822 his introduction, at Cassel, to another of the g
of his contemporaries, Ludwig Spohr. During thi
his pen was even more prolific than before, prod
among other works, an opera, in three acts, entitl
beiden Neffen, oder Der Onkel aus Boston, and a pian
concerto, which he played in public at a concert
by Frau Anna Milder.

It had long been a custom with the Mendelssohn
to give musical performances on alternate Sunday mo
in their dining room, with a small orchestra, which
always conducted, even when he was not tall enou
be seen without standing upon a stool. For each o
occasions he produced some new work, playing the
forte pieces himself, or entrusting them to Fanny,
his sister Rebecka sang, and his brother Paul play
violoncello. In this way *Die beiden Neffen* wa
privately performed, on the fifteenth anniversary
birthday, February 3, 1824. Between the 3d and th
of March, in this year, he composed his fine symph
C minor, now known as Op. 10, and soon afterwar
quartett in B minor, Op. 3, and the (posthumous)
forte sestett, Op. 110. In this year also began his
friendship with Moscheles, who, when asked to receiv
as a pupil, said, "If he wishes to take a hint fro
as to anything new to him, he can easily do so;
stands in no need of lessons."

In 1825 Abraham Mendelssohn took Felix to
where among other musicians then resident in the
apital he met the two most popular dramatic com
of the age, Rossini and Meyerbeer, and lived on
of intimacy with Hummel, Kalkbrenner, Rode, B
Herz, and many other artists of European celebrity
this occasion, also, he made his first acquaintance
Cherubini, who, though he rarely praised any one, exp
a very high opinion of his talent, and recommende
to write a *Kyrie*, for five voices, with full orc
accompaniments, which he himself described as "exc

xless" anything he had attempted. From letters at this period we learn that Felix's estimate of the school of music was very far from a flattering nt he formed some friendships in Paris, which easantly renewed on later occasions. He returned in with his father in May 1825, taking leave of risian friends on the 19th of the month, and pting his journey at Weimar for the purpose of a second visit to Goethe, to whom he dedicated his t in B minor. On reaching home he must have to work with greater zeal than ever; for on the July in this same year he completed his pianoforte io in F sharp minor (Op. 5), and on the 10th of an opera, in two acts, called *Die Hochzeit des ho*, a work of considerable importance, concerning we shall presently have to speak more particularly ordinary boy could have escaped uninjured from ares attendant upon such a life as that which ssohn now lived. Notwithstanding his overwhelm sion for music, his general education had been so red for that he was able to hold his own, in the of his seniors, with the easy grace of an accomplished the world. He was already recognized as a leading irit by the artists with whom he associated, and rtists were men of acknowledged talent and position. mptations to egoism by which he was surrounded have rendered most clever students intolerable. But ural amiability of his disposition, and the healthy ce of his happy home life, counteracted all tendencies s inordinate self-assertion; and he is described by o knew him at this period as the most charming aginable. Even Zelter, though by nature no less ive than Cherubini, was not ashamed to show that proud of him; and Moscheles, whose name was famous, met him from the first on equal terms.

after his return from Paris, Abraham Mendelssohn d from his mother's residence to No. 3 Leipziger , a roomy, old-fashioned house, containing an t music-room, and in the grounds adjoining a enhaus" capable of accommodating several hundred at the Sunday performances.[1] In the autumn following year this "garden-house" witnessed a able private performance of the work by means of the greatness of Mendelssohn's genius was first d to the outer world—the overture to Shakespeare's *mmer Night's Dream*. The finished score of this composition is dated "Berlin, August 6, 1826,"

to say, three days after its author had attained the seventeen years and a half. Yet we may safely that in no later work does he exhibit more originality ght, more freshness of conception, or more perfect y over the details of technical construction, than delightful inspiration, which, though now nearly ears old, still holds its place at the head of the most t achievements of our modern schools. The overas first publicly performed at Stettin, in February under the direction of the young composer, who his bright patent of artistic nobility to support his was at once accepted as the leader of a new and characteristic manifestation of the spirit of modern ss. Henceforth therefore we must speak of him, not udent, but as a mature and experienced artist.

nwhile *Camacho's Wedding* had been submitted to General-Musik-Director Spontini, with a view to its tion at the opera. The libretto, founded upon an e in the history of Don Quixote, was written by manu, and Mendelssohn threw himself into the spirit of the romance with a keen perception of its humour. The work was put into rehearsal soon af composer's return from Stettin, produced on Ap 1827, and received with great apparent enthusiasm for some reason which it is now impossible to a a cabal was formed against it, and it never reached a performance. The critics abused it mercilessly, exhibits merits of a very high order. The solemn for the trombones, which heralds the first appear the knight of La Mancha, is conceived in a sp reverent appreciation of the idea of Cervantes, would have done honour to a composer of experience. Even the critics suborned to condem work could not refrain from expressing their adm of this—but it had been decreed that the opera not live—and it did not.

Mendelssohn was excessively annoyed at this m and some time elapsed before his mind recovered it bright tone, but he continued to work diligently cause of art. Among other serious undertakin formed a choir for the study of the great choral of Sebastian Bach, then entirely unknown to the and, in spite of Zelter's determined opposition, succeeded, in 1829, in inducing the Berlin Singak to give a public performance of the *Passion accor St Matthew*, under his direction, with a chorus of three and four hundred voices. The scheme su beyond his warmest hopes, and proved the me restoring to the world great compositions with wh are all now familiar, but which, at that time, had nev heard since the death of Bach. But the obstructiv were grievously offended; and at this period Mend was far from popular among the musicians of Berli

In April 1829 Mendelssohn paid his first v London. His reception was most enthusiastic. H his first appearance before an English audience at the Philharmonic Society's concerts—then held Argyll Rooms on the 25th of May, conduct symphony in C minor from the pianoforte, to which led by John Cramer. On the 30th he played *Concertstück*, from memory, a proceeding at tha extremely unusual. At a concert given by Dronet, 24th of June, he played Beethoven's pianoforte con E flat, which had never before been heard in the c and the overture to *A Midsummer Night's Dream* w for the first time, presented to a London audienc returning home from the concert, Mr. Attwood organist of St Paul's Cathedral, left the score overture in a hackney coach, whereupon Mend wrote out another, from memory, without an err another concert he played, with Moscheles, his s published concerto in E, for two pianofortes and or After the close of the London season he starte Klingemann on a tour through Scotland, where inspired with the first idea of his overture to *Fingal*, returning to Berlin at the end of No Except for an accident to his knee, which lamed some considerable time, his visit was a highly u one, and laid the foundation of many firm friendsh many prosperous negotiations in the time to come.

The visit to England formed in reality the firs only of a great scheme of travel which his father him to extend to all the most important art c Europe. After refusing the offer of a professo Berlin, he started again, in May 1830, for Italy, on his way at Weimar, where he spent a memorab night with Goethe, and reaching Rome, after many interruptions, on November 1. No possible excitement ever prevented him from devoting a time every day to composition, but he lost no oppo

[1] After Mendelssohn's death this house was sold to the Prussian ment; and the "Herrenhaus" now stands on the site of the house.

ing either the countless treasures which form the
ory of the great city or the manners and customs of
Romans. He attended, with insatiable curiosity,
ices in the Sistine Chapel; and his keen power of
tion enabled him to throw much interesting light
hem. His letters on this subject, however, lose
f their value through his incapacity to comprehend
e relation existing between the music of Pale-trina
s contemporaries and the ritual of the Roman
. His Lutheran education kept him in ignorance
the first principles of ordinary chanting, and it
ing to find him describing as enormities peculiar
papal choir customs familiar to every village singer
land, and as closely connected with the structure of
nglican chant' as with that of "Gregorian music."
hough he could not agree, in all points, with Baini,
atest ecclesiastical musician then living, he fully
his admiration for the *Improperia*, the *Miserere*, and
tus plenus of the *Lamentationes* and the *Exultet*,
sical beauty of which he could understand, apart
heir ritual significance.

assing through Munich on his return in October 1831,
posed and played his pianoforte concerto in G minor,
epted a commission (never fulfilled) to compose an
for the Munich theatre. Pausing for a time at
rt, Frankfort, and Düsseldorf, he arrived in Paris
ember, and passed four pleasant months in the
l of acquaintances formed in 1825, and in close
rse with Liszt and Chopin. On February 19,
the overture to *A Midsummer Night's Dream* was
at the Conservatoire, and many of his other com
ns were brought before the public, but he did not
her escape disappointments with regard to some of
especially the Reformation symphony, and the visit
ought to a premature close in March by an attack
ver, from which, however, he rapidly recovered.
the 23d of April 1832 he was again in London,
he twice played his G minor concerto at the
rmonic concerts, gave a performance on the organ
Paul's, and published his first book of *Lieder ohne*

He returned to Berlin in July, and during the
he gave public performances of his Reformation
ony, his concerto in G minor, and his *Walpur-
ht*. In the following spring he paid a third visit
ndon for the purpose of conducting his Italian
ony, which was played for the first time, by the
rmonic Society, on the 13th of May 1833. On the
f the same month he conducted the performances at
wer Rhine festival at Düsseldorf, with such brilliant
that he was at once invited to accept the appointment
neral music director to the town, an office which
ed the management of the music in the principal
es at the theatre and at the rooms of two musical
ations. This post he willingly accepted, and it formed
ping stone to a far more important one.

ore entering upon his new duties, Mendelssohn paid
rth visit to London, with his father, returning to
ldorf on the 27th of September 1833. His influence
ed an excellent effect upon the church music and in
ncert-room, but his relations with the management
theatre were not altogether pleasant; and it was
ly this circumstance which first led him to forsake
ltivation of the opera for that of sacred music. At
ldorf he first designed his famous oratorio *St Paul*,
onse to an application from the Cacilien-Verein at
fort, composed his overture to *Die schöne Melusine*,
anned some other works of importance. He liked his
tment, and would probably have retained it much
had he not been invited to undertake the permanent
on of the Gewandhaus concerts at Leipsic, and thus
raised to the highest position attainable in the G
musical world. To this new sphere of labour he re
in August 1835, opening the first concert at the Ge
haus, on the 4th of October, with his overture
Meeresstille, a work possessing great attractions, t
by no means on a level with the *Midsummer
Dream*, *The Isles of Fingal*, or *Melusine*.

Mendelssohn's reception in Leipsic was most enthus
and under their new director the Gewandhaus co
prospered exceedingly. Meanwhile *St Paul* steadi
gressed, and was first produced, with triumphant s
at the Lower Rhine festival at Düsseldorf, on M
1836. On October 3 it was first sung in Engl
Liverpool, under the direction of Sir George Smart
on March 16, 1837, Mendelssohn again directed
Leipsic.

The next great event in Mendelssohn's life was his
marriage, on March 28, 1837, to Cecile Charlotte
Jeanrenaud, whose amiable disposition, surpassing b
and indescribable charm of manner endeared her
who knew her. The honeymoon was scarcely over
he was again summoned to England to conduct *St*
at the Birmingham festival, on September 20th.
this visit he played on the organ at St Paul's
Christ Church, Newgate Street, with an effect
exercised a lasting influence upon English organis
was here also that he first contemplated the proc
of his second oratorio, *Elijah*.

Passing over the composition of the *Lobgesang* in

events on which space does not permit us to enlarge,
Mendelssohn in 1841 recalled to Berlin by the k
Prussia, with the title of Kapellmeister. Thoug
appointment resulted in the production of *Antigone*,
Colonos, *Athalie*, the incidental music to the *Mid
Night's Dream*, and other great works, it proved an
source of vexation, and certainly helped to shorten th
poser's life. In 1842 he came to England for the
time, accompanied by his wife, conducted his
symphony at the Philharmonic, again played the o
St Peter's, Cornhill, and Christ Church, Newgate
and was received with all possible honour by the qu
the prince consort. He did not, however, permit
engagements to interfere with the direction of the G
haus concerts; and in 1843 he founded in Leipsic th
conservatoire which soon became the best musical
in Europe, opening it on April 3, in the buildings
Gewandhaus. In 1844 he conducted six of the
monic concerts in London, producing his new *Mid
Night's Dream* music, and playing Beethoven's pia
concerto in G with extraordinary effect. He retu
his duties at Berlin in September, but happily su
in persuading the king to free him from his most
engagements, and his delight at this relief w
bounded.

After a brief residence in Frankfort, Mend
returned to Leipsic in September 1845, resum
old duties at the Gewandhaus, and teaching re
in the conservatoire. Here he remained, with li
terruption, during the winter,—introducing his
Jenny Lind, then at the height of her popula
the critical frequenters of the Gewandhaus, and
working at *Elijah*, the first performance of which

a serious inroad upon the composer's health.
return to Leipsic he worked on as usual, but

hat his health was seriously impaired. In 1847 he England for the tenth and last time, to conduct four nances of *Elijah* at Exeter Hall, on the 16th, 23d, and 30th of April, one at Manchester on the 20th, e at Birmingham on the 27th. Again the queen rince consort received him with marked respect,—ight almost venture to say, affection,—and all seemed rous and happy. But the necessary exertion was yond his strength. He witnessed Jenny Lind's first ance at Her Majesty's Theatre, on the 4th of May, and gland on the 9th, little anticipating the trial that d him in the tidings of the sudden death of his sister , which reached him only a few days after his arrival nkfort. The loss of his mother in 1842 had shaken uch, but the suddenness with which this last sad gence was communicated broke him down com . He fell to the ground insensible, and never fully red. In June he was so far himself again that he ble to travel, with his family, by short stages, to aken, where he stayed for some time, illustrating ourney by a series of water-colour drawings, but g no attempt at composition for many weeks. He ed to Leipsic in September, bringing with him nts of *Christus*, *Loreley*, and some other unfinished taking no part in the concerts, and living in the st privacy. On the 9th of October he called on ne Frege, and asked her to sing his latest set of songs. ft the room for lights, and on her return found him ent pain, and almost insensible. It was the begin- f the end. He lingered on, now better now worse, gh four weary weeks, and on the 4th of November ssed away, in the presence of his wife, his brother, is three dear friends, Moscheles, Schleinitz, and and David. A cross now marks the site of his in the Alte Dreifaltigkeits Kirchhof, at Berlin.

delssohn's title to a place among the greatest composers of tury is incontestable. His style, though differing but little nical arrangement from that of his classical predecessors, is erized by a vein of melody peculiarly his own, and easily nishable by those who have studied his works, not only e genuine effusions of contemporary writers, but from the uccessful of the servile imitations with which, even during time, the music-shops were deluged. In less judicious hands id symmetry of his phrasing might, perhaps, have palled e ear; but under his skilful management it serves only to an additional charm to thoughts which derive their chief from the evident spontaneity of their conception. In this, l other matters of a purely technical character, he regarded epted laws of art as the medium by which he might most ly attain the ends dictated by the inspiration of his genius. caring nothing for rules, except as means for producing effect, he scarcely ever violated them, and was never weary of sing their value upon the minds of his pupils. His method terpoint was modelled in close accordance with that practised astian Bach. This he used in combination with an elastic ment of the sonata-form, similar to that engrafted by ven upon the lines laid down by Haydn. The principles d in this arrangement were strictly conservative; yet they l him, at the very outset of his career, to invent a new style original than that of Schubert or Weber, and no less re- le as the embodiment of canons already consecrated by l authority than as a special manifestation of individual

It is thus that Mendelssohn stands before us as at the same champion of conservatism and an apostle of progress; and iefly by virtue of these two apparently incongruous though perfectly compatible phases of his artistic character that his ce and example have, for so many years, held in check the e of reactionary opinion which a little injudicious en- ement might easily have fanned into revolutionary fury. y, this wholesome influence is still at work among us; and oratorios, his symphonies, his overtures, his concertos, and naller pianoforte pieces Mendelssohn sets before us an ex the value of which is universally recognized, and not likely to forgotten.

cerning Mendelssohn's private character there have never vo opinions. As a man of the world, he was more than ordi- accomplished,—brilliant in conversation, and in his lighter ts overflowing with sparkling humour and ready pleasantry, loyal and unselfish in the more serious business of life, an weary of working for the general good. As a friend he varyingly kind, sympathetic, and as true as steel. His ca as a Christian needs no stronger testimony than that allo his own delineation of the character of St Paul; but it is much to say that his heart and life were pure as those of child.

A complete list of Mendelssohn's published compositions—one hundred teen in number, besides some five and twenty unnumbered works of co importance—will be found in the thematic catalogue published by Mes kopf and Härtel at Leipsic, and also in Grove's *Dictionary of M Musicians*, vol. II. pp. 308, 309. Among his miscellaneous writings, we tion a translation of the *Andria* of Terence, in German verse, and an collection of letters, posthumously printed, and calculated to give t a far closer acquaintance with his life and character than any biographer to convey. (W

MENDELSSOHN, Moses (1729–1786), philo and scholar, well known as Lessing's friend and the type of his "Nathan," was born on September 6, 1 Dessau on the Elbe, where his Jewish father made a livelihood by teaching a small school and trans copies of the "law." The leading events of Mendel career have been indicated elsewhere (see Jews, v p. 680). His numerous writings include *Ueber d in metaphysischen Wissenschaften* (1763), which the prize in a competition in which Immanuel Kan part; *Briefe über die Empfindungen* (1764); *Phaedo über die Unsterblichkeit der Seele* (1767), an argum immortality, founded on the nature of the soul as e ing it from the ordinary laws of change, which ha severely criticized by Kant; *Jerusalem, oder die r Macht und Judenthum* (1783), a specially importa tribution to the question of Jewish emancipat number of contributions to his friend Nicolai's *Li briefen* and *Bibliothek der schonen Wissenschaften*; two tracts in Hebrew; and some new German trans from the Old Testament. The controversy which the publication of his *Morgenstunden* (1785-86), to Jacobi's *Briefe über die Lehre Spinoza's*, is said been more or less directly the cause of his death, took place on January 4, 1786 (see Jacobi, vol. 537). Of Mendelssohn's three sons, the second, Ab settled as a banker in Hamburg and married a Jewe Salomon Bartholdy, who bore him four children; th advice of their mother's brother, himself a consci convert from Judaism, were educated as Christian thenceforth joined their mother's second surname t own. The second of them, Felix, is the subject preceding notice. In later life Abraham Mend was accustomed to say, "When I was young I w son of my father; now I am the father of my son. *The Mendelssohn Family*, 1882.

MENDOZA, a city of the Argentine Republic, t town of the province of Mendoza, lies 700 miles north-west of Buenos Ayres, at the foot of the Cord 2510 feet above the sea level, in 32° 53′ S. lat. and W. long. It was formerly a frequent stopping-place route across the Andes by the Uspallata Pass, and rank as one of the best built towns in the country, 1861 it was almost completely destroyed by an ap earthquake, in which the people, for the mos collected in the churches, perished to the num about 12,000. Bravard, a French geologist who ha predicted the catastrophe, was one of those who pe Extensive ruins still mark the site of the old tow new town, which has been built at a little distan grown rapidly. Situated in a richly cultivated Mendoza depends mainly on agriculture and fruit g

The city was founded in 1559 by Garcia de Mendoza, 1776 it was made the administrative centre of the vice-r La Plata. See Mulhall, *Handbook of the La Plata State* and Mrs Mulhall, *Between the Amazon and the Andes*, 188

MENDOZA, Diego Hurtado de (*c.* 1503 novelist, poet, diplomatist, and historian, was a youn of the member of the illustrious Mendoza family t

ernment of Granada was entrusted not long after its
r, and was born in that city about the year 1503.
rquis of Santillana, so prominent a figure at the court
n II. of Castile, was his great grandfather At an
ge Mendoza, who had been destined for the church,
nt to Salamanca, where he studied with success, and
me time between the years 1520 and 1525, produced
arillo de Tormes, the work upon which his literary
y largely rests. Having persuaded his father to
im to enter the army, he served with the Spanish
ot Charles V. in Italy, and also availed himself of
nities as they arose to hear the lectures of famous
ors at Bologna, Padua, and Rome In 1538 he was
nto the diplomatic service of the emperor and sent as
ador to Venice; there he cultivated friendly relations
he Aldi, and energetically set about collecting a

NELAUS, king of Sparta, was the brother of
EMNON (*q.v.*) and the husband of Helena (*q.v.*). He
e of the heroes of the Trojan horse, and recovered
e at the sack of the city. On the voyage home-
his fleet was scattered off Malea by a storm which
him to Crete; after seven years' further wandering
prus, Phoenicia, Egypt, Ethiopia, Libya, and the
of the Erembi, he at last had an interview with
s and obtained a favourable wind which brought him
n the very day on which Orestes was holding the
feast over Ægisthus and Clytaemnestra. After a long and happy life in Lacedaemon, Menelaus, as the in law of Zeus, did not die but was translated to Ely

MENGS, Antony Raphael (1728 1779), was the celebrated representative of the eclectic school of pai in the 18th century, and played a great part in the days of the classic revival. He was born in 1728 at A in Bohemia, but his father, a Danish painter, establ himself finally at Dresden, whence in 1741 he conduct son to Rome. Mengs early showed that active intelli and large capacity for laborious study which secured the extraordinary distinction which he enjoyed throug His appointment in 1749 as first painter to the elec Saxony did not prevent his spending much time in I where he had married in 1748, and abjured the Prote faith, and where he became in 1754 director of the Va school of painting, nor did this hinder him on two occa from obeying the call of Charles III. of Spain to Ma There Mengs produced some of his best work, specially the ceiling of the banqueting hall, the subj which was the Triumph of Trajan and the Temple of C After the completion of this work in 1777, Mengs returned to Rome, and there he died, two years lat poor circumstances, leaving twenty children, seven of were pensioned by the king of Spain. Besides num paintings in the Madrid gallery, the Ascension at Dre Perseus and Andromeda at St Petersburg, and the c of the Villa Albani must be mentioned among his works. In England, the duke of Northumberland sesses a Holy Family, and the colleges of All Soul Magdalen, at Oxford, have altar-pieces by his hand his writings, in Spanish, Italian, and German, Meng put forth his eclectic theory of art, which treats of lection as attainable by a well schemed combinati diverse excellences,—Greek design, with the expr of Raphael, the chiaroscuro of Correggio, and the c of Titian. His close intimacy with Winkelmann— constantly wrote at his dictation - has greatly enh his historical importance, for he formed no scholars the critic must now concur in Goethe's judgment of M in *Winkelmann und seine Jahrhundert*; he must de that so much learning should have been allied to a want of initiative and utter poverty of invention embodied with a strained and artificial mannerism.

See *Opere di Antonio Raffaello Mengs*, Parma, 1780; *Werke, übersetzt v. C. F. Prange*, 1786, *Zeitschrift für bi Kunst*, 1880; Bianconi, *Elogio Storico di Mengs*, Milan, Nagler's *Kunstlerlexikon*.

MENHADEN, economically one of the most impo fishes of the United States, known by a great nu of local names, "menhaden" and "mossbunker" those most generally in use. In systematic works pears under the names of *Clupea menhaden* and *Br tus tyrannus*. It is allied to the European species of and pilchard, and, like the latter, approaches the coast wanderings in immense shoals, which are found throu the year in some part of the littoral waters between and Florida, the northern shoals retiring into deeper or to more southern latitudes with the approach of weather. The average size of the menhaden is abo inches. Although it was long known as a palatable fish, and largely used, when salted, for export to the Indies, and as bait for cod and mackerel, the menh fishery has been developed to its present importance within the last twenty years. A large fleet of ste and sailing vessels is engaged in it; and a great num large factories have sprung into existence to extract th which is used for tanning and currying, and for adul ing other more expensive oils, and to manufacture the into a very valuable guano. In the year 1877 2,42 gallons of oil and 55,444 tons of guano were prod

ged to the Netherlands in 1815, and became part of Belgium

NINGITIS (from *μῆνιγξ*, a membrane), a term in
ne applied to inflammation affecting the membranes
brain (cerebral meningitis) or spinal cord (spinal
gitis) or both.

erebral meningitis there are two varieties:- (1) that
the presence of tubercle in the membranes of the
which gives rise to the disease known as tubercular
gitis, or acute hydrocephalus; and (2) simple or
meningitis, which may arise from various causes.
g the more common are injuries of the head, exten
f disease from contiguous parts, such as erysipelas of
alp or caries of the bones of the ear, exposure to
r to extreme heat, the presence of tumours in the
nce of the brain. It may likewise occur in the
of fevers, rheumatism, and inflammatory affections,
so as a result of mental overwork, sleeplessness, and
lic excess. This latter variety of meningitis is less
on than the former, but it is on the whole more
ble to treatment. The symptoms present such a
l resemblance to those already described in tubercular
gitis that it is unnecessary to refer to them in detail
(YDROCEPHALUS), and the treatment is essentially the
for both.

nal meningitis, or inflammation of the membranes
ing the spinal cord, generally results from causes of
ilar kind to those producing cerebral meningitis,—
es, exposure to cold or sudden changes of tempera
diseases affecting adjacent parts such as the vertebral
n or the spinal cord itself, or extension downwards
ammation of the membranes of the brain. It is said
most common in males. As in the case of the brain,
embranes become extremely congested; exudation of
and effusion of serum follow; and the spinal cord
oots of the nerves become more or less involved in
orbid process.

e chief symptoms are fever, with severe pain in the
or loins shooting downwards into the limbs (which
he seat of frequent painful involuntary startings),
panied with a feeling of tightness round the body.
ocal symptoms bear reference to the portion of the
the membranes of which are involved. Thus when
nflammation is located in the cervical portion the
es of the arms and chest are spasmodically contracted.
here may be difficulty of swallowing or breathing, or
rrassed heart's action, while when the disease is seated
lower portion, the lower limbs and the bladder and
n are the parts affected in this way. At first there
is excited sensibility (hyperæsthesia) in the parts o
surface of the body in relation with the portion of
affected. As the disease advances these symptoms
place to those of partial loss of power in the aff
muscles, and also partial anæsthesia. These va
phenomena may entirely pass away, and the patient
some weeks or months recover; or, on the other hand,
may increase, and end in permanent paralysis.

The treatment is directed to allaying the pain
inflammatory action by opiates. Ergot of rye is str
recommended by many physicians. The patient s
have perfect rest in the recumbent, or better still i
prone, position. Cold applications to the spine may
use, while scrupulous attention to the functions o
bladder and bowels, and to the condition of the skin
the view of preventing bed-sores, is all important.

Epidemic Cerebro-spinal Meningitis.- This name, as w
cerebro spinal fever, is applied to a disease defined in the *Nom
tion of Diseases* as "a malignant epidemic fever, attended by p
contractions of the muscles of the neck and retraction of the
In certain epidemics it is frequently accompanied by a profus
purpuric eruption, and occasionally by secondary effusions into
joints. Lesions of the brain and spinal cord are found on disse
This disease appears to have been first distinctly recognized
year 1837, when it prevailed as an epidemic in the south-e
France, chiefly among troops in garrison. For several years
quently it existed in various other localities in France, and
among soldiers. At the same time in other countries in w
and central Europe the disease was observed in epidemic outb
both among civil and military populations. In 1846 it first s
itself in Ireland, chiefly among the inmates of workhouses in
and Dublin. Numerous outbreaks occurred also about thi
period in many parts of the United States. In more recen
the disease has repeatedly appeared both in Europe and A
but it has seldom prevailed extensively in any one tract of co
the outbreaks affecting for the most part limited communitie
as garrisons or camps, schools, workhouses, and prisons.

Little is known regarding the causation of this disease. A
seem liable to suffer, and, as regards sex, males are affecte
commonly than females. Occupation and condition of life
to exercise no influence. It has been observed to occu
frequently in cold seasons. The question of the contagio
of cerebro spinal fever remains still unsettled, but the we
authority appears to be in favour of the theory of the comm
bility of the disease. It cannot, however, be regarded as com
in the same degree as some other specific fevers, such as typhu
small-pox, or scarlatina.

The following are the more prominent symptoms. Afte
days of general discomfort the attack comes on sharply with
intense headache, giddiness, and vomiting. Neuralgic p
the abdomen, and pain with spasmodic contractions in the
of the extremities, occur at an early stage. The headache co
with great severity, and restlessness and delirium supervene,
panied with periods of somnolence. The pains and spasms
increase, the muscles of the neck, spine, and limbs being sp
affected. The patient's head is drawn backwards and rigidl
the spine arched, and the arms and legs powerfully flex
whole condition bearing a considerable resemblance to t
For a time there is greatly increased sensibility of the ski
being excited by the slightest contact. There is more or le
present. About the fourth day of the disease an eruption
skin both of the face and body frequently appears, in th
either of purpuric spots or small clear vesicles. Death m
place in from a few hours to eight or ten days. Should the
survive the immediate shock of the attack, serious compl
are apt to appear in the form of destructive inflammation
eyes or ears, inflammation with effusion into certain join
paralysis of limbs; or, again, recovery may take place afte
longed convalescence. The mortality appears to vary in d
epidemics, in some being as high as 80 per cent., in othe
about 20 per cent. Certain forms of the disease are of ma
character from the first, and very rapidly fatal.

The changes found after death in cerebro-spinal fever are
inflammation of the membrane of the brain and spinal co
effusion of serum or pus into the ventricular and arachnoid

The treatment is similar to that of other febrile conditio
for the special symptoms of pain, spasm, &c., opium seems
been found of eminent service, while quinine and ergot of
also recommended.

MENNONITES is a name borne by certain Ch
communities in Europe and America, denoting
adherence to a type of doctrine of which Menno S

ndeed the originator, but the chief exponent at when the anti-pædo-baptism of the congregations he laboured took permanent form in opposition ary Protestantism on the one hand and to the c ideas of the Munster type of anabaptism on the The original home of the views afterwards called te was in Zurich, where, as early as 1525, Grebel nz founded a community having for its most dismark baptism upon confession of faith. The chief s of these Zürich Baptists have been already stated ticle BAPTISTS, vol. iii. p. 353. The main interest ect lay not in dogma but in discipline. Within munities evangelical life was reduced to a law of on from the world, and this separation enforced ngent use of excommunication and the prohibition age beyond the brotherhood involved not only e from worldly vanities but refusal of civic duties te being held to be un Christian)—refusal to take o use the sword. In their revolt against the cor- of the mediæval church the Reformers neither he continuity of the church as an organization nor d the Christian character of the state. The new both, and their position thus appeared so radically ve of the foundations of society that it is not sur under the imperfect views of toleration then current, y became the objects of bitter persecution from nts as well as from Catholics. But the Grebelians lesire, like the fanatics of Münster, to found a new y in opposition to the anti Christian state. They nly to withdraw from what their conscience con content to live as strangers upon earth, and devot their energy to preserve the purity of their own nities. The mediæval conception of separation from ld as the true path of Christian perfection had l all middle class society in Europe, and prepared accept separatist views of the church as soon as re reached by the impulse of revolt against Roman ism; the pursuit of holiness in a society protected ct discipline is an ideal which experience has shown a great attraction for one class of earnest minds; spite of persecutions incomparably fiercer than the larger Protestant bodies ever underwent, the trine and praxis rapidly spread from Switzerland nany, Holland, and even to France. Each com- was quite independent, united to the rest only by a love. There was no sort of hierarchy, but only ers" chosen by the congregation, of whom the ominent were also "elders" entrusted with the ration of the sacraments—an organization so easily ve of reproduced that the movement could hardly ted by any persecution short of the total annihila ch at length was actually the fate of many of the mmunities. The remnants of the Swiss Mennonites 1620 into two parties, the stricter of which, the tes or Upland Mennonites, were distinguished from land Mennonites by holding that excommunication arty dissolved marriage, and by their rejection of and the use of the razor. Their persecution lasted 0; a few congregations still remain and keep es quite distinct from Baptist bodies of more origin. In Germany the Mennonites are some- ore numerous; more important are the German te colonies in southern Russia, brought thither in the empress Catherine, which in turn have recently ny emigrants to America. America indeed, and y Pennsylvania, early became a refuge for the tes of Switzerland, the Palatinate, and Holland, now the chief home of the body (175,000 in the States and 25,000 in Canada). The oldest con- is that of Germantown (since 1683); the most numerous of several divisions are the Old Mennonites, corresponding to the less strict of the Swiss sections.

All these communities in Europe and America are distinguished by an antique simplicity combined with antique prejudices, by indifference to the interests of the greater world, while at the same time their industry and self-concentration have made them generally well-to-do. Their religious type has varied very little in the course of centuries, as indeed is not surprising, their theology being ascetic rather than dogmatic or speculative. The Mennonites of Holland, on the other hand, have passed through an interesting and progressive history.

It was in Holland and the adjoining parts of Low Germany that the personal influence of Menno Simons (1492–1559) was mainly felt. He was originally a priest, and was pastor at his native place Witmarsum in Friesland from 1531 to 1536, when convictions long ripening in his mind compelled him to resign his cure. At this time the anti-pædo-baptist societies in the Low Countries were much agitated. The views which had just before received their political deathblow at Munster (see ANABAPTISTS) were not extinct, and even those who did not share them were by no means at one. Menno attached himself to the Obbenites, who held that on earth true Christians had no prospect but to suffer persecution, refused to use the sword, and looked for no millennium on earth. Menno became one of their elders, and by his wanderings among the scattered and oppressed communities, and especially by the natural eloquence and religious power of his numerous writings, did much to sustain the faith of his associates, to confirm the type of their religious life, and to prevent startling aberrations in doctrine or discipline. He was not an original thinker; but the love which all felt for the man, and which was kept alive for generations by his writings, gave him the place which the name of Mennonites expresses.

It may be ascribed to the influence of Menno's writings that the Dutch Mennonites, though for a time (since 1554) they broke into fractions on questions of discipline, and especially on the effect of excommunication upon marriage, never fell so far apart as regards the type of their religious life as to preclude the possibility of reunion. The Waterlanders in North Holland, who held the least strict doctrine of excommunication, soon moved farther in the direction of liberality, and exchanged the name Mennonites for that of Doopsgezinden (Baptist persuasion). In 1579 they refused to condemn any one for opinions, even on the incarnation, which the word of Scripture did not pronounce necessary to salvation. They aided William the Silent with money, and from 1581 to 1618 even accepted civil office. Meantime the stricter party had undergone various divisions, which, however, in 1627–32 were reunited on the basis of confessions essentially embodying Menno's teachings. They too had learned moderation, at least in their views of excommunication, and their antithesis to the state was softened since the cessation of persecution in 1581, but especially since in 1672 they were recognized as citizens. On the other hand, the adoption of a confession had deepened the separation between them and the liberal Doopsgezinden; but doctrine was never the fundamental principle of the Mennonite communities, confessionalism took no firm root, and the two sections gradually approached, and through a series of partial fusions became at length finally united when the Amsterdam congregations came together in 1801. The persuasion declined much in numbers in the 18th century; since then it has increased, and has now 127 congregations with nearly 50,000 members. The objection to hold civil office disappeared in 1795; that to carry arms in the war of freedom against Napoleon. Baptism on profession of faith and the refusal of the oath, tolerance in matters of doctrine without religious indifference, are the chief marks of the body, which in point of theological culture and general enlightenment, philanthropic zeal and social importance, has long stood very high.

Authorities. The best life of Menno Simons is Cramer's, 1837. De Hoop Scheffer's article in Herzog-Plitt, *R. E.*, is excellent; only one point of consequence in his account seems to call for modification,—the book against John of Leyden said to have been published before Menno joined the Obbenites, is almost certainly spurious. See Sepp, *Geschiedkundige Nasporingen*, 1. (1872) p. 128 *sq.* The completest edition of Menno's works is that in folio, 1686. Many of them are known only in bad Dutch versions; Menno himself wrote in the "Oostersch" or East Sea Dialect of Low German. For the literature on the Mennonites in general, see De Hoop Scheffer, on whom the foregoing sketch is mainly dependent.

MENSHIKOFF, ALEXANDER DANILOVICH (1672–1729), born at Moscow on the 17th of November (o.s.) 1672, was the son of a poor man, who employed him to sell cakes about the streets of that city. In this humble occupation he attracted the attention of Lefort, one of Peter the Great's most active co-operators, who was pleased with his sprightliness, and took him into his service. Peter, soon afterwards

the youn at Lefort's, was also delighted with him, ok him to be his page. Menshikoff soon became nsable to the czar, assisting him in his workshop, playing signal bravery in the company of his master siege of Azoff. He formed one of the suite of Peter his travels, and worked with him at Saardam and rd. Throughout his wars with the Swedes, Men- was the companion of the czar, and greatly distin- l himself. For his gallantry at the battle of the on the 7th of May (o.s.) 1703, he received the order Andrew. In 1704 he was made general, and at the of the czar created a prince of the Holy Roman e. His house on the Vasilii-Ostroff was magnificent; mbassadors were received, and banquets were given us with gold and silver plate. Unfortunately there rk side to the picture, and the favourite was guilty rtion to such an extent as to bring him under his 's censure. On the death of Peter the position of ikoff became very perilous; his successes had raised him a host of enemies eager for his downfall. The ns, Dolgoroukis, and all those who formed what may ed the Old Russian party, wished to proclaim the Alexis emperor. Those, however, whose aggrandize- was bound up with Peter's reforms—Menshikoff, sin, Bontourlin, Goloffkin, and others— were in favour ng the crown to Peter's widow, who accordingly ed the throne as Catherine I. During her reign the ce of Menshikoff was unbounded, and he virtually ed the country; but the empress died in 1727, reign of two years. She had made a will, no at the instigation of the favourite, to the effect eter, her grandson, was to be czar under the guardian- Menshikoff, whose daughter Mary was to be married youthful sovereign. Under pretence of taking care young czar, Menshikoff caused him to be removed house and surrounded him with his creatures. He w at the height of his power; foreign ambassadors ed that even the great Peter himself was never so much. The young czar, however, showed no on for Mary Menshikoff, and the girl was equally tic towards her betrothed, being in love with a r of the family of Sapieha at the time her father orced her into the engagement. The Dolgoroukis he aversion of the young prince to his *fiancée* as a means of creating dislike to the father. A chain of e was gradually leading to the downfall of the favo He was soon refused admittance to the summer p whither the young czar had retired. Next he was arr and so overpowered was he at his disgrace tha had an apoplectic stroke. In vain did he address l both to the emperor and his sister. Shortly atte order of the czar, the fallen magnate departed St Petersburg, but more like a nobleman retiring t estate than a culprit going into exile. The people reg him with dislike, and most of them rejoiced over hi On his way a courier arrived with orders to tak czar's ring of betrothal from his daughter Mary an her back her own, which had been worn by Pet Menshikoff was not permitted to pass through Mo but was conducted to Oranienburg, in the govern Riazan, and there placed under strict surveillance. afterwards the whole family was banished to Siberia arrived at Berezoff towards the end of 1727. Menshi wife died on the journey, and was buried near Kazan. the arrival of the prisoners they were lodged in a w house, consisting of four rooms. But Menshikoff di long endure the horrors of exile in this inclement re According to Mannstein, he died (November 12, 1729) of an apoplectic stroke, because there was n at Berezoff, as he himself remarked, who understood to open a vein. The young czar ordered the release exile of the two remaining children of Menshikoff, daughter Mary had died at Berezoff in the same as her father, and restored some of their proper them.

MENSHIKOFF, Alexander Sergeievich (1787–1 great-grandson of Peter's favourite, born in 1787, e the Russian service as attaché to the embassy at Vienna accompanied the emperor Alexander throughout his paigns against Napoleon, and attained the rank of ge but retired from active service in 1823. He then de himself to naval matters, and put the Russian n which had fallen into decay during the reign of Alex on an efficient footing. On the outbreak of the Cr War he was appointed commander in chief, and suff severe defeat at the Alma. On the death of the em Nicholas in 1855 he was recalled, ostensibly on ac of failing health. He died in 1869.

MENSURATION

ENSURATION, or the art of measuring, involves the construction of measures, the methods of using and the investigation of rules by which magnitudes it may be difficult or impossible to measure directly lculated from the ascertained value of some associated tude. It is usual, however, to employ the term ration in the last of these senses; and we may ore define it to be that department of mathematical e by which the various dimensions of bodies are ated from the simplest possible measurements.

determination of the lengths and directions of nt lines, including what are familiarly known as ms in heights and distances, generally depends on olution of triangles, and will be discussed in the s Trigonometry and Surveying. The remaining ns of the subject are the determinations of the s of curves, the areas of plane or other figures, and olumes and surfaces of solids; and it is of mensura s thus restricted that the present article will discuss of the more important problems.

Units of Length, Area, and Volume.—In measuring agnitude we select some standard or "unit" to measure by. Thus in measuring length we take for u inch, a foot, or a yard. From the unit of length we the units of area and volume. Thus we define the u area to be the area of the square described upon th of length, and the unit of volume to be the volume cube whose edge is the unit of length or whose side unit of area. For example, if an inch be taken as th of length, the square whose side is 1 inch is the u area, and the cube whose edge is 1 inch is the u volume. The length of a line, the area of a surfac the volume of a solid are then expressed by the nu whole or fractional, of units of length, area, and v which they respectively contain. Hence, if l deno linear unit, the length of a line which contains a units or simply a since l is unity; similarly the area of a s which contains b units of area is bm, or simply b, m is the unit of area.

§ 2. *Commensurable and Incommensurable Magnitu* When two magnitudes have a common measure, t when another magnitude can be found which is co in each an exact number of times, they are said "commensurable." Thus a line 4½ and another 3½

e commensurable; for, if $\frac{1}{9}$ inch be taken as unit of the former contains the unit nine times and the seven times. If no common measure can be found, o magnitudes are said to be "incommensurable" stance, 1 and $\sqrt{2}$ have no common measure; for ·1112 . . . an interminable decimal, and hence no owever small, can be found which will be contained an exact number of times. If, however, we take ·1, the error will be less than $\frac{1}{10}$, if $\sqrt{2}$ 1·111, ror will be less than $\frac{1}{10000}$, &c. Hence, by taking a nt number of figures, we can find a fraction which ffer from $\sqrt{2}$ by less than any assignable quantity, herefore we can always find two commensurable ades that will represent two incommensurable ones degree of accuracy we please. In what follows we herefore only consider commensurable lines.

Area of a Rectangle.—Let the side AB (fig. 1) con units and the side BC b units of length. If we AB into a equal parts, qual to the unit of length, milarly BC into b equal nd it through the points ision we draw lines l to the sides of the gle, these lines will di e rectangle into a series angles, each of which t of area, since each is are whose sides are of ngth. As we have a rows of these rectangles, and ch row, the whole number of rectangles will be ab. ore

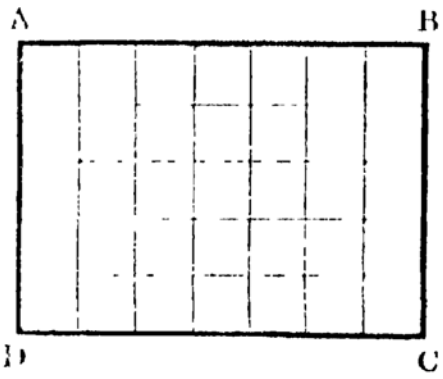

Fig. 1

area of ABCD ab units of area
ab

PART I.—PLANE FIGURES.

ON I. PLANE FIGURES CONTAINED BY STRAIGHT LINES.

A. *The Rectangle.*

Let ABCD (fig. 2) be a rectangle, and let AB = CD = a, = b, AC = c, and the angle ; it is required to find its area. rectangle is completely de- d when two independent data, which at least is a length, are onnecting its parts, we can de its area in the following cases.

When its length a and its breadth b are given.—It has already been proved

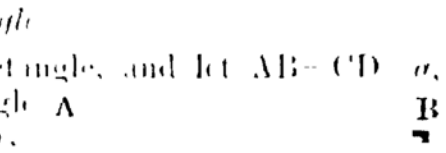

Fig. 2.

area of ABCD $= ab$;

rea of a rectangle is equal to its length multiplied by its

ple.—Let a = 12 feet 6 inches and b = 9 inches, then

area of ABCD = 12·5 × ·75 = 9·375 square feet.

ake use of logarithms in the above calculation we have

$$\log \text{area} = \log a + \log b,$$

$\log a$	$\log 12{\cdot}5$	1·0969100
$\log b$	$\log\ {\cdot}75$	1·8750613
$\log \text{area}$		
area		9·375

When a side a and the diagonal c are given.—By Euclid have

$$b^2 = c^2 - a^2, \text{ or } b = \sqrt{c^2 - a^2},$$

$$\text{area of ABCD} = ab = a\sqrt{c^2 - a^2},$$

$$\log \text{area} = \log a + \tfrac{1}{2}\log(c^2 - a^2) + \tfrac{1}{2}\log(c + a).$$

ple.—Let a = 238 and c = 456, then

$\log a$	$\log 238$	2·3765770
$\frac{1}{2}\log(c+a)$	$\frac{1}{2}\log 694$	1·4206797
$\frac{1}{2}\log(c-a)$	$\frac{1}{2}\log 218$	1·1692282
$\log \text{area}$		4·9664849;
area		= 92573·1.

(γ) When a side a and α its inclination to the diagonal are given.—Since

$$\frac{b}{a} = \tan\alpha, \quad b = a\tan\alpha,$$

and therefore area of ABCD = $ab = a^2\tan\alpha$;

or $\log \text{area} = 2\log a + \text{L}\tan\alpha - 10$.

Example. Let a = 36 and α = 32° 25′ 15″, then

$2\log a = 2\log 36 = 3{\cdot}1126050$

$\text{L}\tan\alpha = \text{L}\tan 32° 25′ 15″ = 9{\cdot}8028622$

therefore $\log \text{area} = 12{\cdot}9154672 - 10 = 2{\cdot}9154672$;

hence area = 823·127.

(δ) When the diagonal c and α its inclination to either of the sides are given.—We have

$$a = c\cos\alpha, \text{ and } b = c\sin\alpha,$$

therefore area of ABCD $= ab = c^2\sin\alpha\cos\alpha = \frac{1}{2}c^2\sin 2\alpha$;

or $2\,\text{area} = c^2\sin 2\alpha$,

and hence $\log 2\,\text{area} = 2\log c + \text{L}\sin 2\alpha - 10$.

§ 5. A square being a rectangle whose sides are equal, we can at once determine its area. When one datum, which must be a length, is given the square is completely determined, and hence we have only two cases to consider.

(α) When the side is given.—From § 4, α, we have at once

$$\text{area of square} = ab = a \times a = a^2.$$

(β) When the diagonal c is given.—From § 4, β, we have

$$a^2 + a^2 = c^2, \text{ or } a^2 = \tfrac{1}{2}c^2;$$

hence area of square $= a^2 = \frac{1}{2}c^2$, or $2\,\text{area} = c^2$;

and therefore $\log 2\,\text{area} = 2\log c$.

B. *Right-angled Triangles.*

§ 6. The diagonal of every rectangle divides it into two equivalent right angled triangles (Euel. i. 34), and hence the area of the right-angled triangle ABC (fig. 2) is equal to half the area of the corresponding rectangle ABCD.

C. *Triangles Generally.*

§ 7. In every triangle there are six elements to be considered, namely, the three sides and the three angles. If any three of these six be given, provided one is a length, the triangle is completely determined, and hence its area can be found.

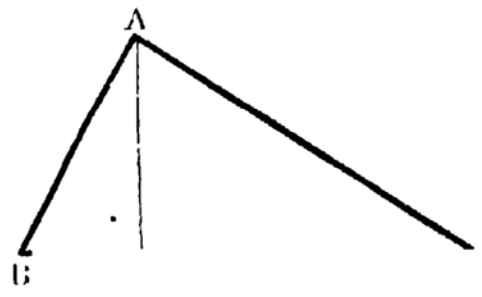

Fig. 3

§ 8. *Length of Perpendiculars of a Triangle.*—In the triangle ABC (fig. 3) let BC = a, CA = b, AB = c, AD the perpendicular from A on BC = h, BD = x, and CD = y.

Since BDA and CDA are right angles, we have

$$c^2 = x^2 + h^2, \text{ and } b^2 = y^2 + h^2,$$

and therefore

$$b^2 - c^2 = y^2 - x^2 = (y + x)(y - x) = a(y - x);$$

whence $$y - x = \frac{b^2 - c^2}{a}.$$

But $y + x = a$, and, by solving these equations, we obtain

$$y = \frac{b^2 + a^2 - c^2}{2a}.$$

Again

$$h^2 = b^2 - y^2 = b^2 - \left(\frac{b^2 + a^2 - c^2}{2a}\right)^2 = \frac{(2ab)^2 - (b^2 + a^2 - c^2)^2}{4a^2}$$

$$= \frac{(a + b + c)(b + c - a)(c + a - b)(a + b - c)}{4a^2};$$

hence $$h = \frac{1}{2a}\sqrt{(a+b+c)(b+c-a)(c+a-b)(a+b-c)}.$$

Now let $a + b + c = 2s$, then $b + c - a = 2(s - a)$, $c + a - b = 2(s - b)$, and $a + b - c = 2(s - c)$.

Therefore, on substituting and reducing, we obtain

$$h = \frac{2}{a}\sqrt{s(s-a)(s-b)(s-c)}.$$

Similarly the perpendiculars from B and C on the opposite sides are respectively

$$\frac{2}{b}\sqrt{s(s-a)(s-b)(s-c)}, \text{ and } \frac{2}{c}\sqrt{s(s-a)(s-b)(s-c)}.$$

§ 9. We now proceed to investigate formulæ for the area of a triangle in the following important cases.

(α) When the base a and the altitude h are given.—Since a

is equel to half a rectangle of the same base and altitude, at once

$$\text{area ABC} = \tfrac{1}{2}ah.$$

ple. Let $a = 40$ chains and $h = 14{\cdot}52$ chains, then

$$\text{area} = \tfrac{1}{2} \times 40 \times 14{\cdot}52 = 290{\cdot}4 \text{ square chains.}$$

Then two sides a *and* c *and the included angle* B *are given.*—

g. 3 $\dfrac{h}{c} = \sin B$, and therefore $h = c\sin B$;

$$\text{area} = \tfrac{1}{2}ah = \tfrac{1}{2}ac\sin B;$$

$$\log 2\text{area} = \log a + \log c + L\sin B - 10.$$

ple.—Let $a = 40$, $c = 30$, and $B = 30°$, then

$$\text{area} = \tfrac{1}{2}ac\sin B = \tfrac{1}{2} \times 40 \times 30 \times \tfrac{1}{2} = 300.$$

Then the three sides a, b, c *are given.*—From § 8

$$h = \frac{2}{a}\sqrt{s(s-a)(s-b)(s-c)},$$

efore

$$\tfrac{1}{2}ah = \tfrac{1}{2}a \times \frac{2}{a}\sqrt{s(s-a)(s-b)(s-c)} = \sqrt{s(s-a)(s-b)(s-c)};$$

ogarea $= \tfrac{1}{2}\{\log s + \log(s-a) + \log(s-b) + \log(s-c)\}$.

$a + b + c$, we have

rea of triangle $= \tfrac{1}{4}\sqrt{2(a^2b^2 + b^2c^2 + c^2a^2) - (a^4 + b^4 + c^4)}$.

ple 1.—Let $a = 13$, $b = 14$, and $c = 15$, then

$s = \tfrac{1}{2}(13 + 14 + 15) = 21$, $s - a = 21 - 13 = 8$,
$s - b = 21 - 14 = 7$, and $s - c = 21 - 15 = 6$;

$$\text{area} = \sqrt{21 \cdot 8 \cdot 7 \cdot 6} = 84.$$

ple 2.—Let $a = 255$, $b = 238$, and $c = 221$, then

log s	log 357	= 2·5526682
log $(s-a)$	log 102	= 2·0086002
log $(s-b)$	log 119	= 2·0755470
log $(s-c)$	log 136	= 2·1335389

$$\log\text{area} = \tfrac{1}{2}(8{\cdot}7703543) = 4{\cdot}3851771;$$

$$\text{area} = 24276.$$

Then any two angles B *and* C *and the adjacent side* a *are* Since

$$\frac{c}{a} = \frac{\sin C}{\sin A}, \qquad c = \frac{a\sin C}{\sin A},$$

efore (by β)

ea $= \tfrac{1}{2}ac\sin B = \dfrac{a^2\sin B\sin C}{2\sin A}$, where $A = 180° - (B + C)$,

$$\log 2\text{area} = 2\log a + L\sin B + L\sin C + L\operatorname{cosec} A - 30.$$

l the angles of a triangle are given when any two are e can find the area of a triangle when any two angles and side are given. Thus, when A, B, and c are given, we know nd the problem reduces to a case of the preceding.

Then the three medians α, β, γ *are given.*—If a, b, c be the les of a triangle, and α, β, γ the three medians, *i.e.*, the awn from the angles to the middle points of the opposite en by well-known geometrical propositions we have

$$4(\alpha^2 + \beta^2 + \gamma^2) = 3(a^2 + b^2 + c^2),$$
$$16(\alpha^2\beta^2 + \beta^2\gamma^2 + \gamma^2\alpha^2) = 9(a^2b^2 + b^2c^2 + c^2a^2),$$
$$16(\alpha^4 + \beta^4 + \gamma^4) = 9(a^4 + b^4 + c^4).$$

9, γ)

riangle $= \tfrac{1}{4}\sqrt{2(a^2b^2 + b^2c^2 + c^2a^2) - (a^4 + b^4 + c^4)}$,

$= \tfrac{3}{4}\sqrt{2(\alpha^2\beta^2 + \beta^2\gamma^2 + \gamma^2\alpha^2) - (\alpha^4 + \beta^4 + \gamma^4)}$.

D. *Parallelograms*

The opposite sides and angles of a parallelogram being three independent e of which at least th, are necessary and t to determine it ly.

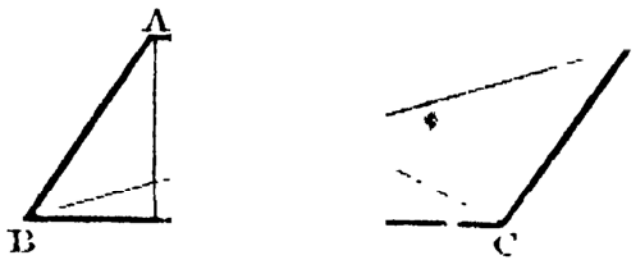

Fig. 4.

parallelogram ABCD let BC = DA = a,) = b, AC = c, AE = h, ngle ABC = α and 3.

the diagonal AC divides the parallelogram into two equi- riangles, we obtain

$$\text{area of ABCD} = 2 \text{ area of triangle ABC} = 2 \times \tfrac{1}{2}a \times h \ (\S\ 9,\ \alpha) = ah;$$

$$\text{rea of ABCD} = 2 \text{ area ABC} = 2 \times \tfrac{1}{2}ab\sin\alpha \ (\S\ 9,\ \beta) = ab\sin\alpha;$$

$$\log\text{area} = \log a + \log b + L\sin\alpha - 10;$$

$$\text{area of ABCD} = 2 \text{ area ABC} = 2(\text{ABO} + \text{CBO})$$
$$= 2\{\tfrac{1}{2}\text{BO.AO}\sin\text{AOB} + \tfrac{1}{2}\text{BO.CO}\sin\text{COB}\} = 2\{\tfrac{1}{2}\text{BO.AC}\sin\beta\}$$
$$= \tfrac{1}{2}\text{BD.AC}\sin\beta = \tfrac{1}{2}cd\sin\beta,$$

$$\log 2\text{area} = \log c + \log d + L\sin\beta - 10.$$

§ 11. If the parallelogram be *equiangular* (a rectangle and area = $\tfrac{1}{2}c^2\sin\beta$. If it be *equilateral* (a rhombus), β area = $\tfrac{1}{2}cd$. If it be both *equiangular* and *equilateral* (a $c = d$ and $\beta = 90°$, and area = $\tfrac{1}{2}c^2$ as before (§ 5, β).

E. *Trapeziums*

§ 12. To determine a trapezium completely four data a sary and sufficient.

In the trapezium ABCD (fig. 5) let BC = a, CD = b, DA = c,

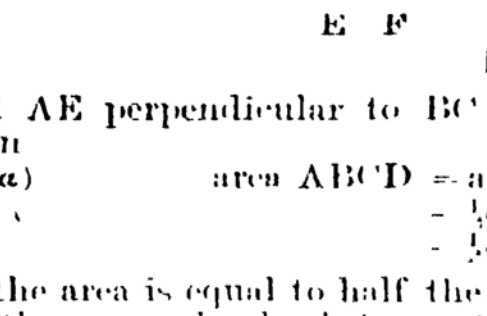

Fig. 5.

and AE perpendicular to BC = h, and draw AF parallel then

$$(\alpha)\qquad \text{area ABCD} = \text{area ABC} + \text{area ADC} = \tfrac{1}{2}ah + \tfrac{1}{2}ch = \tfrac{1}{2}(a + c)h;$$

or the area is equal to half the sum of the parallel sides m by the perpendicular between them.

Again, area of ABF = $\tfrac{1}{2}$BF · AE (§ 9, α) = $\tfrac{1}{2}(a - c)h$,

also $\text{area of ABF} = \sqrt{s(s - \text{AB})(s - \text{BF})(s - \text{FA})}$,

where $2s = \text{AB} + \text{BF} + \text{FA}$:

$$h = \frac{2}{a - c}\sqrt{s(s - \text{AB})(s - \text{BF})(s - \text{FA})}, \text{ therefore}$$

$$(\beta)\qquad \text{area of ABCD} = \tfrac{1}{2}(a + c)h = \frac{a + c}{a - c}\sqrt{s(s - \text{AB})(s - \text{BF})(}$$

$$= \frac{1}{4}\frac{a + c}{a}\sqrt{(a + b + c + d)(a + b - c - d)(a + b - c + d)(a - b -}$$

since $\text{AB} = d$, $\text{BF} = a - c$, and $\text{FA} = \text{CD} = b$.

Thus we can find the area of a trapezium in terms of its si

§ 13. If $c = 0$, ABCD becomes a triangle, and its area

$$= \tfrac{1}{4}\sqrt{(-a + b + d)(a + b - d)(a + b + d)(a - b + d)}.$$

Again, if $c = a$, then also $b = d$, and ABCD becomes a p gram, and its area takes the indeterminate form $\frac{0}{0}$, as it sh since four sides do not completely determine a parallelogra

F. *Quadrilaterals Generally.*

§ 14. A quadrilateral is completely determined when fi pendent data are given. We consider the following cases.

(α) *When any diagonal and the perpendiculars on it opposite vertices are given.*

The quadrilateral ABCD (fig. 6) = ABD + BCD
$= \tfrac{1}{2}$BD.AE + $\tfrac{1}{2}$BD.CF
$= \tfrac{1}{2}$BD(AE + CF);

or the area is equal to half the product of the diagonal sum of the perpendiculars.

If the diagonal BD fall without the figure, as in the concave quadrilateral ABCD (fig. 7), then it is clear that

area ABCD = $\tfrac{1}{2}$BD(AE − CF).

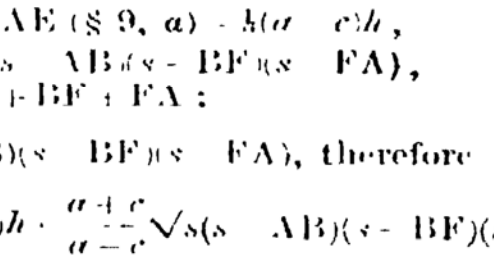

Fig. 6.

(β) *When the diagonals and their included angle are given.*—In the quadrilateral ABCD (fig 8, p. 10) let BD = h, AC = k, and angle DEA =

ABCD = ABD + BCD
= $\tfrac{1}{2}$BD.AE sin α + $\tfrac{1}{2}$BD.CE sin α (§ 10, γ)
= $\tfrac{1}{2}h$(AE + CE) sin α
= $\tfrac{1}{2}hk\sin\alpha$;

or the area is equal to the product of the diagonals and th their contained angle.

The same result holds when one of the diagonals falls without the quadrilateral, as in fig. 7, as the reader can easily verify.

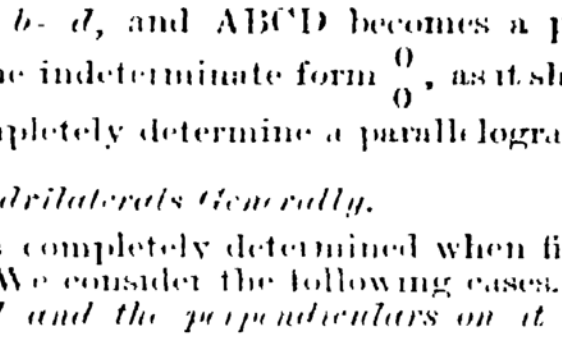

Fig. 7.

(γ) *When the four sides and the angle between the diagonals are given.*—If a, b, c, d be the sides and α the angle between the diagonals it can easily be shown that

$$\text{area of quadrilateral} = \tfrac{1}{4}(a^2 - b^2 + c^2 - d^2)\tan\alpha.$$

When the four sides are given and the opposite angles are supplementary.—In fig. 8 let AB = a, BC = b, CD = c, DA = d, angle ABC = α, angle β, and let $\alpha + \beta = 180°$.

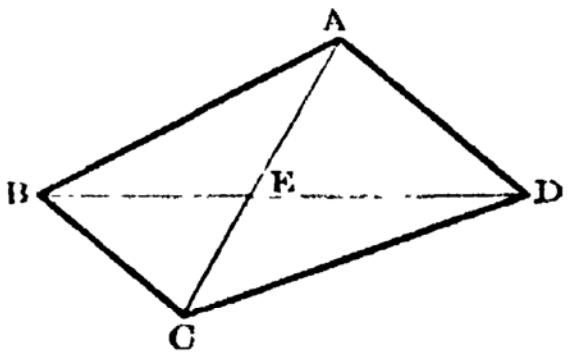

Fig. 8.

$$\text{ABCD} = \text{ABC} + \text{ADC}$$
$$= \tfrac{1}{2}ab\sin\alpha + \tfrac{1}{2}cd\sin\beta$$

$$\sin\beta = \sin(180° - \alpha) = \sin\alpha,$$

hence

$$\text{area of ABCD} = \tfrac{1}{2}(ab + cd)\sin\alpha.$$

This gives us the area of the quadrilateral in terms of the four sides and one angle.

Also we have

$$AC^2 = a^2 + b^2 - 2ab\cos\alpha = c^2 + d^2 + 2cd\cos\beta = c^2 + d^2 + 2cd\cos\alpha,$$

whence

$$\cos\alpha = \frac{a^2 + b^2 - c^2 - d^2}{2(ab + cd)}, \text{ and hence}$$

$$1 + \cos\alpha = \frac{(a + b + c - d)(a + b - c + d)}{2(ab + cd)}, \text{ and}$$

$$1 - \cos\alpha = \frac{(c + d + a - b)(c + d - a + b)}{2(ab + cd)}.$$

From this we obtain

$$\sin^2\alpha = (1 + \cos\alpha)(1 - \cos\alpha)$$
$$= \frac{(b + c + d - a)(c + d + a - b)(d + a + b - c)(a + b + c - d)}{4(ab + cd)^2}.$$

Let

$$a + b + c + d = 2s,$$

then

$$\tfrac{1}{2}(ab + cd)\sin\alpha = \sqrt{(s - a)(s - b)(s - c)(s - d)};$$

hence

$$\text{area of ABCD} = \sqrt{(s - a)(s - b)(s - c)(s - d)},$$

and

$$\log(\text{area}) = \tfrac{1}{2}\{\log(s - a) + \log(s - b) + \log(s - c) + \log(s - d)\}.$$

If $\alpha = 0$, the quadrilateral becomes a triangle, and its area is $\sqrt{s(s - a)(s - b)(s - c)}$ as before. In extracting the square root of $\sin^2\alpha$ we take the positive sign, since the angle α is less than two right angles.

G. *Regular Polygons*

Since a regular polygon is both equilateral and equiangular, a circle can be inscribed within it and also described about it, and if we join the n straight lines drawn from the common centre of the circles to the n vertices of the polygon they divide it into n triangles equal in every respect. Therefore the area of the polygon is equal to n times the area of any one of these triangles.

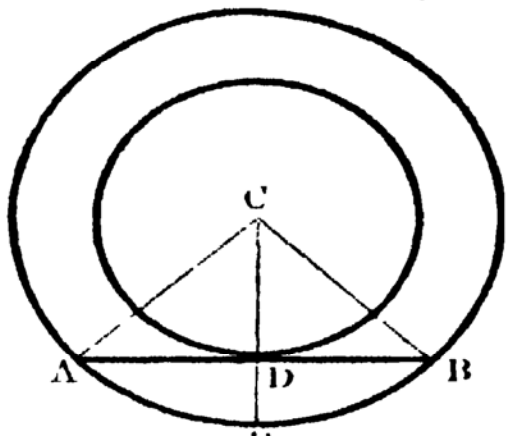

Fig. 9.

Radius of Inscribed and Circumscribed Circles. Let AB (fig. 9) be a side of a regular polygon of n sides, let C be the centre of the inscribed and circumscribed circles, CD r the radius of the inscribed circle, and CE R the radius of the circumscribed circle.

The angle ACB is evidently equal to the nth part of four right angles, that is

$$\text{ACB} = \frac{360°}{n}, \text{ and ACD} = \tfrac{1}{2}\text{ACB} = \frac{180°}{n}.$$

Also

$$\text{AD} = \frac{a}{2} = \text{CD}\tan\text{ACD} = r\tan\frac{180°}{n},$$

and

$$\text{AD} = \frac{a}{2} = \text{AC}\sin\text{ACD} = R\sin\frac{180°}{n};$$

hence

$$r = \frac{a}{2}\cot\frac{180°}{n},$$

and

$$R = \frac{a}{2}\operatorname{cosec}\frac{180°}{n}.$$

Perimeter of Polygon.—The perimeter of the polygon of n sides is na, *i.e.*, $2nr\tan\frac{180°}{n}$, or $2nR\sin\frac{180°}{n}$.

Hence it follows that the perimeters of the inscribed and circumscribed regular polygons of n sides of a circle of radius r are

$$2nr\sin\frac{180°}{n} \text{ and } 2nr\tan\frac{180°}{n} \text{ respectively.}$$

Area of Polygon.

(α) *In terms of* r.—The area of polygon

$$= n\text{ACB} - n\text{AD}.\text{CD} = n \times r^2\tan\frac{180°}{n}$$

(β) *In terms of* R.—The triangle ACB

$$= \tfrac{1}{2}\text{AC}.\text{CB}\sin\text{ACB} = \tfrac{1}{2}R^2\sin\frac{360°}{n},$$

and therefore area of polygon $= \frac{1}{2}nR^2\sin\frac{360°}{n}$.

(γ) *In terms of* a.—The triangle ACB

$$= \tfrac{1}{2}\text{AB}.\text{CD} = \frac{a}{2} \times r = \frac{a}{2} \times \tfrac{1}{2}a\cot\frac{180°}{n} = \frac{a^2}{4}\cot\frac{180°}{n},$$

and therefore area of polygon $= a^2 \times \frac{n}{4}\cot\frac{180°}{n}$,

or

$$\log 4\,\text{area} = \log n + \text{L}\cot\frac{180°}{n} + 2\log a - 10.$$

From α and β it follows that the areas of the inscribed and circumscribed regular polygons of n sides of a circle of radius r are

$$\tfrac{1}{2}nr^2\sin\frac{360°}{n} \text{ and } nr^2\tan\frac{180°}{n} \text{ respectively.}$$

§ 19. In the formula (§ 18, γ) for the area of a polygon the factor $\frac{n}{4}\cot\frac{180°}{n}$ has a definite value for every value of n, and if we find its value once for all for a large number of values and tabulate the results, we can find the area of a regular polygon of n sides by multiplying the square of its side by the appropriate tabular value.

Again, if $a = 1$ we have

$$r = \tfrac{1}{2}\cot\frac{180°}{n} \text{ and } R = \tfrac{1}{2}\operatorname{cosec}\frac{180°}{n};$$

and thus we obtain in a similar manner the radius of the inscribed and circumscribed circles by multiplying the side by the appropriate tabular value of $\frac{1}{2}\cot\frac{180°}{n}$ and $\frac{1}{2}\operatorname{cosec}\frac{180°}{n}$ respectively.

§ 20. The following table contains the values of $\frac{n}{4}\cot\frac{180°}{n}$, their logarithms, and the values of $\frac{1}{2}\cot\frac{180°}{n}$ and $\frac{1}{2}\operatorname{cosec}\frac{180°}{n}$ for values of n from 3 to 12.

n	$\frac{n}{4}\cot\frac{180°}{n}$	Logarithms.	$\frac{1}{2}\cot\frac{180°}{n}$	$\frac{1}{2}\operatorname{cosec}\frac{180°}{n}$
	0·1330127	1·6365006	0·2886751	·577
	1·0000000	0·0000000	0·5000000	·707
	1·7201774	0·2356490	0·6881909	·850
	2·5980762	0·4146519	0·8660254	1·000
	3·6339124	0·5603745	1·0383461	1·152
	4·8284271	0·6838568	1·2071068	1·306
	6·1818242	0·7911166	1·3737387	1·461
	7·6942088	0·8861640	1·5388418	1·618
11	9·3656407	0·9715375	1·7028437	1·775
12	11·1961524	1·0490688	1·8660254	1·931

Let A denote the area of a polygon of n sides and A′ the corresponding tabular value of $\frac{n}{4}\cot\frac{180°}{n}$, then

$$\text{A} = a^2\text{A}',$$

or

$$\log\text{A} = 2\log a + \log\text{A}'.$$

H.—*Length of the Radius of the Inscribed, Escribed, and Circumscribed Circles of a Triangle.*

§ 21. (α) *Radius of Inscribed Circle.* Let O (fig. 10) be the centre of the circle inscribed in the triangle ABC and touching the sides in D, E, and F. Join OA, OB, and OC. The angles at D, E, F are right angles (Euel. iii. 18). Let BC = a, CA = b, AB = c, and OD = OE = OF = r.

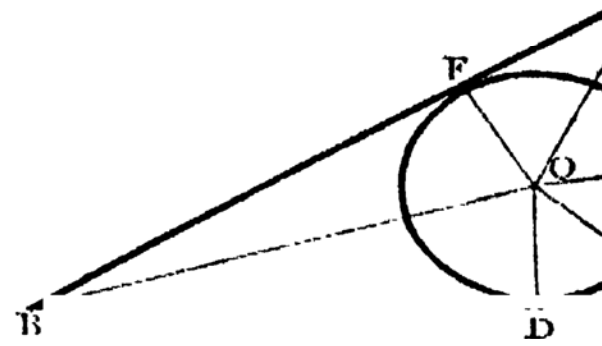

Fig. 10.

Now ABC = BOC + COA + AOB

$$= \tfrac{1}{2}ar + \tfrac{1}{2}br + \tfrac{1}{2}cr = \tfrac{1}{2}(a + b + c)r = rs;$$

whence

$$r = \frac{\text{area of ABC}}{s} = \frac{\sqrt{s(s - a)(s - b)(s - c)}}{s}$$

(β) *Radius of Escribed Circles.*—Let OD = OE = OF = r_a,

$$\text{ABC} = \text{ACO} + \text{ABO} - \text{BOC}$$
$$= \tfrac{1}{2}br_a + \tfrac{1}{2}cr_a - \tfrac{1}{2}ar_a = \tfrac{1}{2}(b + c - a)r_a = r_a(s - a),$$

and

$$r_a = \frac{\text{area of ABC}}{s - a} = \frac{\sqrt{s(s - a)(s - b)(s - c)}}{s - a} = \sqrt{\frac{s(s - b)(s}{s - a}}$$

Similarly

$$r_b = \sqrt{\frac{s(s - a)(s - c)}{s - b}} \text{ and } r_c = \sqrt{\frac{s(s - a)(s - b)}{s \quad c}}.$$

Radius of Circumscribed Circle.—Let AD (fig. 12) = p the dicular from A on the side BC, and AE = 2R the diameter

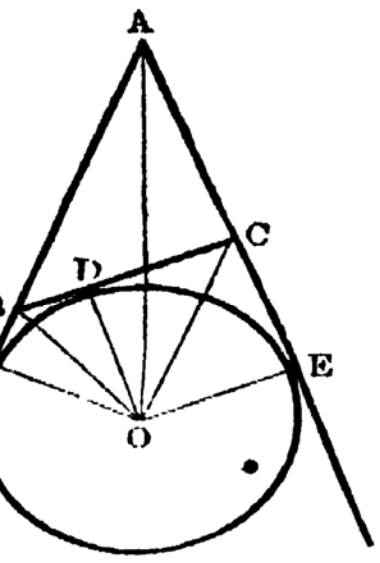

Fig. 11.

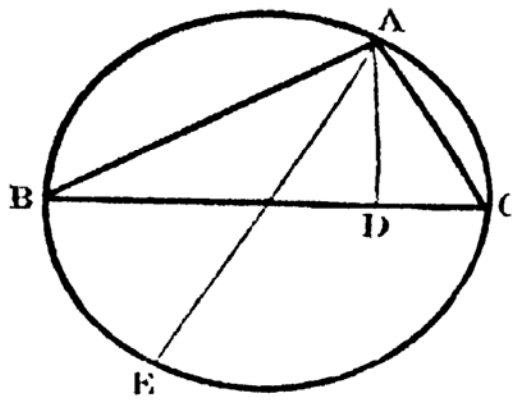

Fig. 12

ircle, then (Euel. vi. C) we have

$$2R \times p = b \times c,$$

e

$$2R \times ap = abc.$$

$= 2\Delta$, where Δ denotes the area of ABC;

$$R = \frac{abc}{4\Delta} = \frac{abc}{4\sqrt{s(s-a)(s-b)(s-c)}}.$$

ple.—Let $a = 13$, $b = 14$, and $c = 15$; then r will be found r_a $10\frac{1}{2}$, r_b 12, r_c 14, and R $8\frac{1}{8}$.

ION II.—PLANE FIGURES CONTAINED BY CURVED LINES.

A. *The Circle.*

Circumference of a Circle.—If we inscribe in any circle a polygon of n sides, and also circumscribe a regular polygon ame number of sides, it is clear that the perimeter of the intermediate between the perimeters of the inscribed and cribed polygons, and that the difference between the peri- f the inscribed and circumscribed polygons can be made as s we please by sufficiently increasing n. A similar state- olds with reference to the areas of the circle and the in- and circumscribed polygons. With the above assumptions ly proved that the circumference of a circle bears a constant its diameter. Hence we have

Circumference = C = constant × radius = constant × r.

ual to denote this constant by 2π, and therefore

$C = 2\pi r = \pi d$, where d is the diameter of the circle.

Numerical Value of π.—The constant π being, as can be roved, an interminable decimal, we can only approximate lue, but this we can do to any degree of accuracy we please. nd σ denote respectively a side of the inscribed and circum- polygons of n sides, and s' and σ' a side of the inscribed umscribed polygons of $2n$ sides, it can easily be shown that

$$(\alpha)\ \sigma = \sqrt{r^2 - (\tfrac{1}{2}s)^2}, \qquad (\beta)\ s'^2 = 2r\left\{r - \sqrt{r^2 - (\tfrac{1}{2}s)^2}\right\}$$

$$(\gamma)\ \sigma' = \frac{rs}{\sqrt{r^2 - (\frac{1}{2}s')^2}}$$

is the radius of the circle.

take $r = \frac{1}{2}$ we find, by means of these formulæ, and by g the value of s when $n = 6$, that the perimeter of inscribed of 96 sides = 3·140 . . . . , and the perimeter of circum- polygon of 96 sides = 3·142. . . .

this we learn that the circumference of the circle, in this is greater than 3·140 . . . . and less than 3·142 . . . . , refore as far as the second place of decimals

$$\pi = 3{\cdot}14.$$

ng greater and greater values of n we obtain closer and proximations to π.

receding method for approximating to the value of π is the afforded by elementary geometry, and is also the oldest; ter and more rapid methods are furnished by the higher atics. The calculation of π has been carried to 707 places nals, the following being the first 20 figures in the result:—

3·14159265358979323846.

practical purposes it is sufficient to take

$$\pi = 3{\cdot}14159 \text{ or } = \frac{355}{133}.$$

The following table contains the functions of π that are of quent occurrence in mensuration:—

	Number.	Logarithm.
π	3·1415927	0·4971499

§ 25. *Units of Angular Measurement.* In measuring select some line of constant length as the standard or uni larly in measuring angles we require to take some angle of magnitude as unit angle. The right angle is by its nature the simplest unit angle, but, for convenience, we take the $\frac{1}{90}$th part of a right angle for unit, and call it a degree, which is subdivided into sixty equal parts called minutes, and these again into sixty equal parts called seconds. For theoretical purposes we define the unit angle to be *the angle subtended at the centre of a circle by an arc equal to the radius.* This angle we call a "radian." In many treatises the radian measure of an angle is called the circular measure.

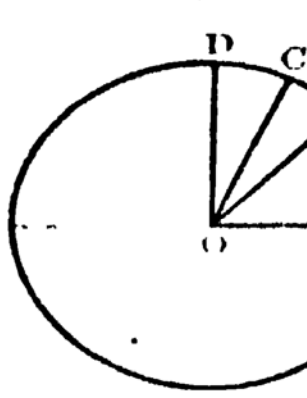

Fig. 13.

§ 26. *The radian is a constant angle.* Let OA (fig. 13) = r, then AOB = 1 radian, and let AOD = 90°, then

$$\text{arc AD} = \tfrac{1}{4} \times 2\pi r = \tfrac{1}{2}\pi r,$$

and, since angles at the centre of a circle are proportiona arcs on which they stand (Euel. vi. 33),

$$\frac{\text{number of degrees in radian AOB}}{\text{number of degrees in AOD}} = \frac{\text{AB}}{\text{AD}} = \frac{r}{\frac{1}{2}\pi r} = \frac{2}{\pi};$$

therefore number of degrees in radian

$$= 90° \times \frac{2}{\pi} = 57°{\cdot}2957795 = \text{constant}.$$

§ 27. *Number of Radians in any Angle.* Let AOC (fig any angle, AOB the radian, and AC = s; then

$$\frac{\text{number of radians in AOC}}{\text{one radian}} = \frac{\text{AC}}{\text{AB}} = \frac{s}{r},$$

therefore number of radians in AOC = $\frac{s}{r}$.

If AOC = 90°, then $s = \frac{1}{2}\pi r$, and number of radians = $\frac{1}{2}\pi$; thus π radians in two and 2π in four right angles.

When $r = 1$ we have number of radians = s, and hence treatises for the number of radians in an angle we find th of the are given

§ 28. *To transfer from degrees to radians and conversely* denote the number of degrees in an angle, and θ the nu radians in the same, then, since $\frac{x}{180} = \frac{\theta}{180}$,

$$(\alpha)\ \theta = \frac{\pi x}{180}, \qquad (\beta)\ x = \frac{180}{\pi}\theta.$$

§ 29. The following table contains the values of θ for x up to 180, and also for minutes and seconds.

Degrees.	Radian.	Degrees.	Radian.	Degrees.	Radian.			
1	·0174533	61	1·0646508	121	2·1118484	1	·002909	1
2	·0349066	62	1·0821041	122	2·1293017	2	·005818	2

20	·3490659	80	1·3962634	140	2·4434610	20	·058178	20
30	·5235988	90	1·5707963	150	2·6179939	30	·087266	30
40	·6981317	100	1·7453293	160	2·7925268	40	·116355	40
50	·8726646	110	1·9198622	170	2·9670597	50	·145444	50
60	1·0471976	120	2·0943951	180	3·1415927	60	·174533	60

example of the use of this table we proceed to find the θ when $x = 68° 45' 17''·8$.

When $x = 68°$ $\theta = 1\cdot1868239$,
$x = 40'$ $\theta = \cdot0116355$,
$x = 5'$ $\theta = \cdot0014544$,
$x = 10''$ $\theta = \cdot0000485$,
$x = 7''$ $\theta = \cdot0000339$,
and when $x = 0''·8$ $\theta = \cdot0000039$,
re when $x = 68° 45' 17''·8$ $\theta = 1\cdot2060001$

Combining the results of §§ 27 and 28 we obtain

$$(\alpha)\quad \theta = \frac{s}{r}, \text{ and } s = \frac{180}{\pi}\cdot\frac{s}{r},$$

$$(\beta)\quad r = \frac{180}{\pi}\cdot\frac{s}{\theta}$$

$$(\gamma)\quad s = r\theta$$

Length of Arcs of Circles. The following are the more im- cases

When terms of the chord of the arc and the radius of the circle are given.— (fig 14) c chord AB, r radius OC or OA, and AEB s, then

$\frac{1}{2}AB = c = r\sin\frac{1}{2}C$, whence C is known, and therefore the arc s is found (§ 30, γ).

When terms of the height of the arc and the radius of the circle are given.— h height of arc, then

$$CD = CE - DE = r - h,$$

$$\cos\tfrac{1}{2}C = \frac{CD}{AC} = \frac{r-h}{r},$$

C is found, and therefore s

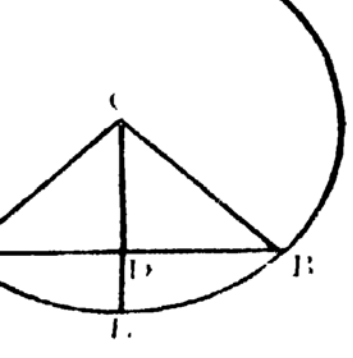

Fig. 14.

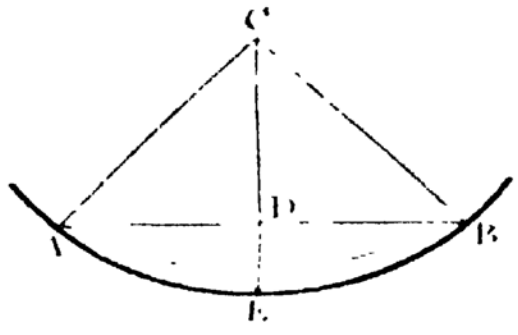

Fig. 15.

Huygens's Approximation to the Length of a Circular Arc. (fig 15) p be the chord of the arc AEB, and $AE = EB = q$ all the arc, then the arc AEB $= \frac{1}{3}(8q - p)$ approximately. r denote the radius, s the arc AEB, and 2θ the angle

hen θ Again, $AB = p = 2AD = 2r\sin\theta = 2r\sin\frac{s}{2r}$

ilarly $q = 2r\sin\frac{s}{4r}$.

$$\sin\theta = \theta - \frac{\theta^3}{3} + \frac{\theta^5}{5} - \&c.,$$

$$p = 2r\left\{\frac{s}{2r} - \frac{1}{3}\left(\frac{s}{2r}\right)^3 + \frac{1}{5}\left(\frac{s}{2r}\right)^5 - \&c.\right\}$$

$$2\cdot3\cdot4\cdot r^3 \quad 2\cdot3\cdot4\cdot5\cdot16\cdot \quad \&c.$$

arly $8q = 16r\left\{\frac{s}{4r} - \frac{1}{3}\left(\frac{s}{4r}\right)^3 + \frac{1}{5}\left(\frac{s}{4r}\right)^5 - \&c.\right\}$

$$4s = \frac{s^3}{2\cdot3\cdot4\cdot r^2} - \frac{s^5}{2\cdot3\cdot4\cdot5\cdot64\cdot r^4} - \&c.$$

, neglecting powers of $\frac{s}{r}$ be- fourth, we obtain

$$p = s\left(1 - \frac{s^4}{7680r^4}\right)$$

mately.

actice it is sometimes more ent to use the equivalent

$$s = 2q + \tfrac{1}{3}(2q - p).$$

Area of Sector of a Circle.— sector be OAB (fig 16). he arc AB into n equal parts, w the chords of these Let P denote the perimeter of the line AB, A the area of the polygon AOB, and ρ the alti-

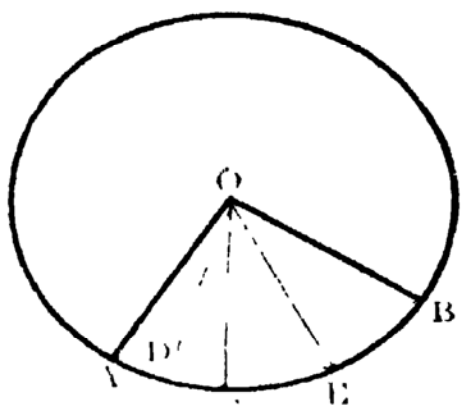

Fig. 16.

tude of any one of the n equal triangles of which this p made up.

Now in the limit, when n is indefinitely increased, P the arc AB $= s$, a result which we symbolize thus—

$$\mathbf{L}_{n=\infty} P = \text{arc AB} = s.$$

Similarly $\mathbf{L}_{n=\infty} \rho = \text{radius} = r$.

Again, the area of the sector is equal to the area of the when the broken line AB becomes the arc AB, that is,

$$\text{sector} = \mathbf{L}_{n=\infty} A = \mathbf{L}_{n=\infty} \tfrac{1}{2}\rho \times P = \tfrac{1}{2}\mathbf{L}_{n=\infty}\rho \times \mathbf{L}_{n=\infty} P = \tfrac{1}{2}rs.$$

§ 34. Let S denote the area of a sector of a circle, then, b of the above result and § 27, we have

$$(\alpha)\quad S = \tfrac{1}{2}sr,$$
$$(\beta)\quad S = \tfrac{1}{2}r\theta \cdot r = \tfrac{1}{2}r^2\theta.$$

§ 35. We proceed to find the area of a sector of a circle in lowing additional cases

(α) *When the chord of the sector and the radius of the ci given.*— In fig 14 let AB $= 2c$, and let AC $= r$, then we have

$$\sin\frac{ACB}{2} = \frac{AD}{AC} = \frac{c}{r},$$

whence ACB and therefore θ is known, and S can be found

ACB has two values, the smaller one giving the area of th and the larger that of the major conjugate sector.

(β) *When the chord and height of the chord are give* DE (fig 14) $= h$ and AB $= 2c$, then

$AC^2 = r^2 = AD^2 + DC^2 = c^2 + (r - h)^2$, whence

$r = \frac{c^2 + h^2}{2h}$, and therefore by previous case the area can be

(γ) *When the chord and angle subtended at the centre a* Let AB (fig 14) $= 2c$ and ACB $= \theta$, then

$$\frac{c}{r} = \sin\frac{ACB}{2}, \text{ or } r = \frac{c}{\sin\frac{1}{2}\theta},$$

therefore area of sector $= \frac{1}{2}r^2\theta = \frac{1}{2}\left(\frac{c}{\sin\frac{1}{2}\theta}\right)^2\theta$.

§ 36. *Area of a Circle.* The circle being a sector whose whole circumference we obtain at once

$$\text{area of circle} = \tfrac{1}{2}r \times s = \tfrac{1}{2}r \times 2\pi r = \pi r^2.$$

An independent proof of this proposition might be means of the inscribed and circumscribed polygons, and area of a circle the area of a sector can be deduced. Th tesimal calculus affords a simple and elegant proof (see § 4

§ 37. If A denote the area, r the radius, $d = 2r$ the diam C the circumference of a circle, we have

$$(\alpha)\quad A = \pi r^2,$$
$$(\beta)\quad A = \tfrac{1}{2}\times 2\pi r \times r = \tfrac{1}{2}Cr,$$
$$(\gamma)\quad A = \frac{4\pi^2r^2}{4\pi} = \frac{C^2}{4\pi},$$
$$(\delta)\quad A = \frac{\pi 4r^2}{4} = \frac{\pi d^2}{4}$$

Whence we see that the area of a circle is obtained by mul

(α) the square of its radius by $\pi = 3\cdot14159$,
(β) the radius by half the circumference,
(γ) the square of the circumference by $\frac{1}{4\pi} = \cdot07957$,
(δ) the square of the diameter by $\frac{1}{4}\pi = \cdot78539$.

§ 38. Again, from the above formulæ we deduce

$$(\alpha)\quad r = \frac{1}{\sqrt{\pi}}\sqrt{A} = \cdot5641896 \times \sqrt{A},$$
$$(\beta)\quad d = \frac{2}{\sqrt{\pi}}\sqrt{A} = 1\cdot1283792 \cdot \sqrt{A},$$
$$(\gamma)\quad c = 2\sqrt{\pi A} = 3\cdot5449077 \times \sqrt{A},$$

thus obtaining radius, diameter, and circumference from ar

§ 39. *Area of a Circular Ring.*—Let r and r_1 denote the the outer and inner circles respectively (fig 17), then the area of the space between them

$$= \pi r^2 - \pi r_1^2 = \pi(r + r_1)(r - r_1).$$

The circles need not be concentric, and the reader should note that the area of the ring is equal to the area of an ellipse whose major and minor axes are $r + r_1$ and $r - r_1$ (see § 51).

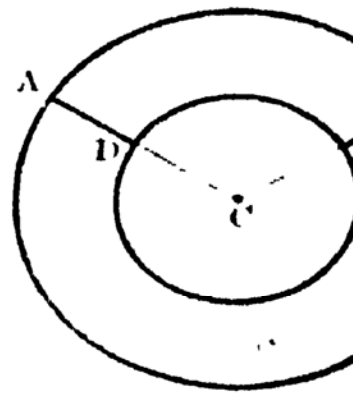

Fig. 17.

§ 40. *Area of the Sector of an Annulus.*—Let angle ACB $= \theta$ in fig. 17, then the area of ABED

$$= \text{sector ACB} - \text{sector DCE}$$
$$= \tfrac{1}{2}r^2\theta - \tfrac{1}{2}r_1^2\theta,$$
$$= \tfrac{1}{2}\theta(r + r_1)(r - r_1).$$

et $AB = l$, $DE = l_1$, and $CA - CD = r - r_1 = h$, then

$$r = \frac{l}{\theta} \text{ and } r_1 = \frac{l_1}{\theta} \text{ : therefore}$$

$$r + r_1 = \frac{1}{\theta}(l + l_1), \text{ and}$$

$$\text{sector} = \tfrac{1}{2}\theta(r + r_1)(r - r_1) = \tfrac{1}{2}\theta\left(\frac{l + l_1}{\theta}\right)h = \tfrac{1}{2}h(l + l_1).$$

Area of a Segment of a Circle. (α) *When the radius and the bended at the centre are given.*—In fig. 14, let AEB be of a circle, then its area

$$= \text{sector ACB} - \text{triangle ACB}$$
$$= \tfrac{1}{2}r^2\theta - \tfrac{1}{2}r^2\sin\theta \text{ (§§ 9, 31)}$$
$$= \tfrac{1}{2}r^2(\theta - \sin\theta).$$

egment be greater than a semicircle $\sin\theta$ is negative and ula becomes

$$\tfrac{1}{2}r^2(\theta + \sin\theta),$$

o geometrically evident.

ht in a similar manner find the area of a segment of a circle

hen the chord and radius are given,
hen the chord and its height are given,
hen the radius and height of the chord are given,
hen the chord and angle subtended by the chord are given

these cases the method of proceeding is obvious, a segment e difference between a sector and a triangle.

Area of a Lune. Let ADB and ACB (fig. 18) be two segf circles, then the area of
- ADBC

ment ADB − segment ACB.

f we so choose our data that determine the areas of the gments we have only to take fference to find the area of e.

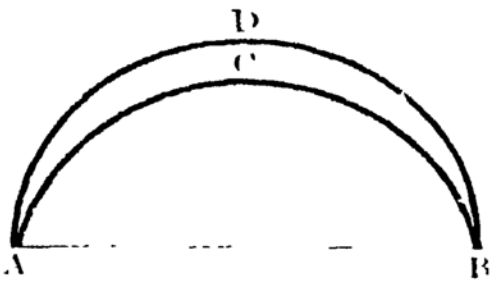

Fig. 18.

Area of a Circular Zone.—
3 and CD (fig. 19) be two chords, then the area of the zone ABCD

= circle − segment AHB − segment DFC;
= segment AED + trapezium ABCD + segment BGC
= 2 segment AED + trapezium ABCD.

The INFINITESIMAL CALCULUS (*q. v.*) furnishes a simple and proof of the formula for the areas of a circle and a sector. (x) be the equation to a plane curve referred to rectangular

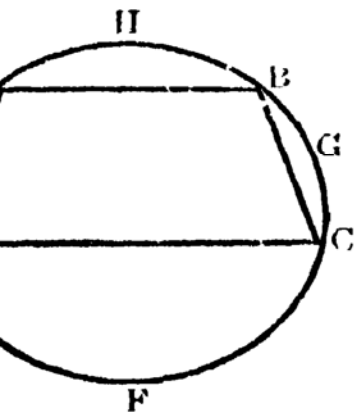

Fig. 19.

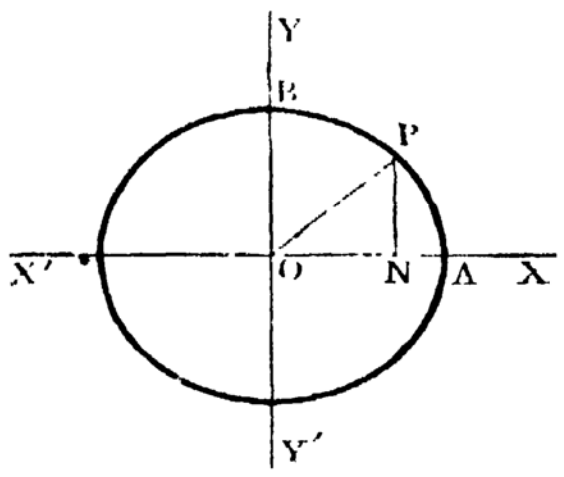

Fig. 20.

hen the area between the curve, the axis of x, and two es corresponding to the abscisse a and b is represented by egral

$$\int_a^b \phi(x)dx.$$

x and y be the coordinates of P (fig. 20), then if $OP = r$ the n to the circle is $y^2 = r^2 - x^2$, and therefore

$$\text{area of quadrant AOB} = \int_0^r \sqrt{r^2 - x^2}\,dx$$

$$= \left[\frac{r^2}{2}\sin^{-1}\frac{x}{r} + \frac{x}{2}\sqrt{r^2 - x^2}\right]_0^r = \frac{r^2}{2} \times \frac{\pi}{2} = \frac{\pi r^2}{4},$$

erefore area of whole circle $= \pi r^2$.

If the equation to a plane curve be given in polar coordi the area bounded by two radii and the curve is equal to

$$\tfrac{1}{2}\int_{\theta_1}^{\theta_2} r^2 d\theta,$$

θ_1 and θ_2 are the values of θ corresponding to the limiting

For example, let AOP (fig. 20) be θ, then area of circle

$$= \tfrac{1}{2}\int_0^{2\pi} d\theta \quad \frac{2\pi r^2}{2} = \pi r^2 \text{ as before.}$$

The area of a sector can be found in a similar manner.

B. *The Parabola*

§ 16. *Length of an Arc of any Plane Curve.*—If a plane c referred to rectangular axes, then the length of any arc curve

$$s = \int \left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}} dx = \int \left\{1 + \left(\frac{dx}{dy}\right)^2\right\}^{\frac{1}{2}} dy$$

taken between proper limits, *i.e.*, the extremities of the ar INFINITESIMAL CALCULUS.

§ 17. *Arc of a Parabola.*—Let the axes of coordinates be

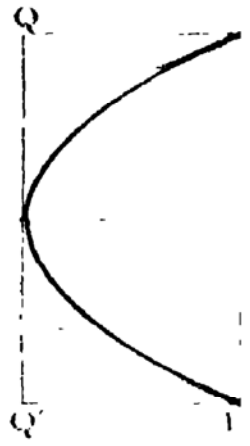

Fig. 21.

of x and the tangent at the vertex A (fig. 21), then, the to the parabola being $y^2 = 2mx$, where $m = 2a$ = latus rec have

$$\frac{dx}{dy} = \frac{y}{m}, \text{ and hence}$$

$$s = \text{arc AP} = \int_0^{y_1} \left\{1 + \frac{y^2}{m^2}\right\}^{\frac{1}{2}} dy$$
$$= \frac{y_1}{m}\sqrt{y_1^2 + m^2} + m\log\frac{y_1 + \sqrt{y_1^2 + m^2}}{m}$$

therefore whole arc PAP′ $= \frac{y_1}{m}\sqrt{y_1^2 + m^2} + m\log\left(\frac{y_1 + \sqrt{y_1^2}}{m}\right.$

Since $y_1^2 = 2mx_1$, the formula may be written

$$\text{PAP}' = \sqrt{4x_1^2 + y_1^2} + \frac{y_1}{2x_1}\log\frac{2x_1 + \sqrt{4x_1^2 + y_1^2}}{y_1}$$

§ 18. *Area of a Parabola.*—Taking the equation to the in the form $y^2 = 4px$, we get

$$\text{area of segment PAP′ (fig. 21)} = 2\int_0^{x_1} 2\sqrt{px}\,dx$$

$$= \tfrac{8}{3}p^{\frac{1}{2}}x_1^{\frac{3}{2}} = \tfrac{2}{3}x_1 y_1$$

From these formulæ we see that the area of a parabolic varies directly as the cube of the square root of the abscissa, and directly as the cube of the ordinate, and that it is equal to $\frac{2}{3}$ rectangle PQQ′P′, or $\frac{4}{3}$ triangle PTP′.

A similar relation holds for the segment cut off by any chord, and thus the area of any parabolic segment can be determined in terms of any data that are sufficient to de termine the segment

§ 49. *Area of a Parabolic Zone.*—Let PM (fig. 22) = y_1, QN = y_2, AM = x_1, AN = x_2, and let the ordinates be inclined to the axis at an angle α.

Area of zone PQQ′P′ = segment PAP′ − segment QAQ′

$$= \frac{y_1^3}{3p} - \frac{y_2^3}{3p} \times \sin\alpha.$$

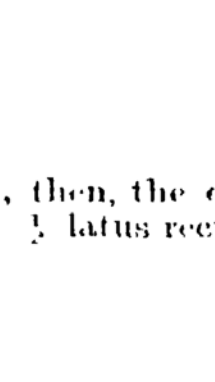

Fig. 2

Now $y_1^2 = 4px_1$ and $y_2^2 = 4px_2$, therefore $\frac{y_1^2 - y_2^2}{4(x_1 - x_2)} = p$, and substituting for p we have area of zone

$$= \tfrac{1}{3}(x_1 - x_2)\left(\frac{y_1^3 - y_2^3}{y_1^2 - y_2^2}\right)\sin\alpha = \tfrac{1}{3}\frac{x_1 - x_2}{y_1 + y_2}(y_1^2 + y_1y_2 + y_2^2)\sin$$

C. *The Ellipse.*

§ 50. *Circumference of an Ellipse.* The equation to th being $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, where a and b are the semiaxes, we have

$\frac{dy}{dx} = -\frac{b^2x}{a^2y}$, and therefore (fig. 23)

of quadrant AB $= \int_0^a \left(\frac{a^2-e^2x^2}{a^2-x^2}\right)^{\frac{1}{2}} dx$, where $e^2 = \frac{a^2-b^2}{a^2}$.

integral may be shown to be equal to the series

$$\frac{\pi a}{2}\left(1 - \frac{e^2}{2^2} - \frac{1\cdot 3e^4}{2^2\cdot 4^2} - \frac{1\cdot 3^2\cdot 5e^6}{2^2\cdot 4^2\cdot 6^2} - \&c.\right),$$

dly converging series when e is a small fraction.

taking more and more of the above series we can ximate as nearly as we to the circumference of an . For example, we have rant AB

$$\left(1 - \frac{e^2}{4}\right) \quad \frac{\pi a}{2}\left(1 - \frac{e^2}{2}\right)^{\frac{1}{2}}$$

a first approximation, whole circumference

$$\left\{\frac{(2a)^2 + (2b)^2}{2}\right\}^{\frac{1}{2}} \text{ nearly.}$$

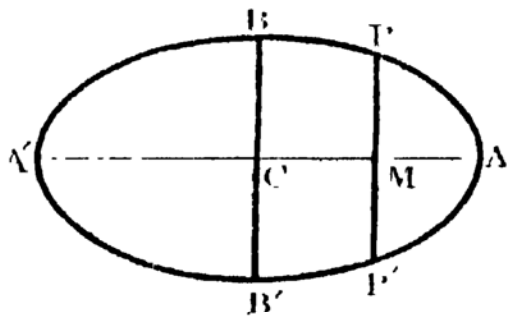

Fig. 23

1. *Area of an Ellipse.*— We have at once

$$\text{area} = 4\int_0^a y\,dx = 4\frac{b}{a}\int_0^a \sqrt{a^2 - x^2}\,dx.$$

$\int_0^a \sqrt{a^2 - x^2}\,dx$ is the area of the quadrant of a circle of radius thus

$$\text{area of ellipse} = 4\frac{b}{a}\frac{\pi a^2}{4} \quad (\S\ 44)$$
$$= \pi ab.$$

following proof is worth the reader's attention. By a well- theorem in conic sections the orthogonal projection of a on a given plane is an ellipse. Now, if A denote the area of ane figure, A′ the area of the projected figure, and θ the angle en the planes it can easily be shown, by dividing the two by planes indefinitely near to each other and perpendicular common section of the planes, that

$$A\cos\theta = A'.$$

case of the circle and ellipse $A = \pi a^2$ and $\cos\theta = \frac{b}{a}$;

$$\text{area of ellipse} = \pi a^2 \frac{b}{a} = \pi ab.$$

2. *Area of an Ellipse in terms of a Pair of Conjugate Diame-* Let a' and b' denote the semiconjugate diameters, and α the between them, then by an elementary property of the ellipse

$$ab = a'b'\sin\alpha;$$

$$\text{area of ellipse} = \pi a'b'\sin\alpha.$$

D. *The Hyperbola.*

3. *Area of a Segment of an Hyperbola.*—The equation of an bola being $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$, we have

$$y = \frac{b}{a}\sqrt{x^2 - a^2};$$ hence (fig. 24)

of the segment PAP′ $= 2\frac{b}{a}\int_a^{x_1}\sqrt{x^2 - a^2}\,dx$

$$= \frac{b}{a}x_1\sqrt{x_1^2 - a^2} - ab\log_e\left(\frac{x_1 + \sqrt{x_1^2 - a^2}}{a}\right)$$

$$= x_1y_1 - ab\log_e\left(\frac{x_1}{a} + \frac{y_1}{b}\right).$$

4. *Area of a Sector of an Hyperbola.* The sector PAP′C is to triangle PCP′ − segment PAP′

$$= x_1y_1 - \left\{x_1y_1 - ab\log_e\left(\frac{x_1}{a} + \frac{y_1}{b}\right)\right\}$$

$$= ab\log_e\left(\frac{x_1}{a} + \frac{y_1}{b}\right).$$

5. *Area of a Zone of an Hyperbola.* In fig. 24 the zone PQ

= segment QAQ′ − segment PAP′

$$= x_2y_2 - ab\log_e\left(\frac{x_2}{a} + \frac{y_2}{b}\right) - x_1y_1 + ab\log_e\left(\frac{x_1}{a} + \frac{y_1}{b}\right)$$

$$= x_2y_2 - x_1y_1 - ab\log_e\left(\frac{ay_2 + bx_2}{ay_1 + bx_1}\right), \text{ where}$$

and x_2, y_2 are the coordinates of P and Q respectively.

If the axes of coordinates be inclined at an angle α, we the above results by $\sin\alpha$ to obtain the correct areas.

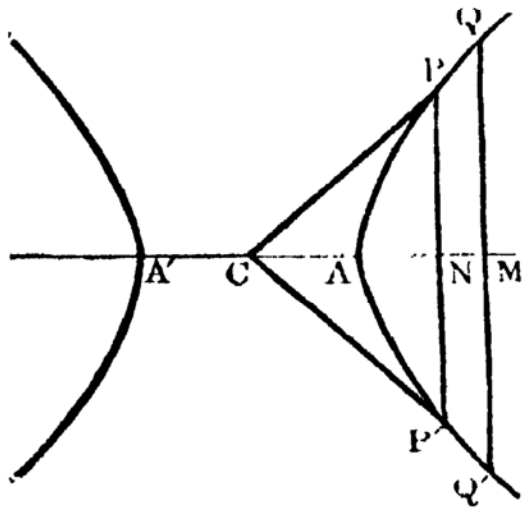

Fig. 24.

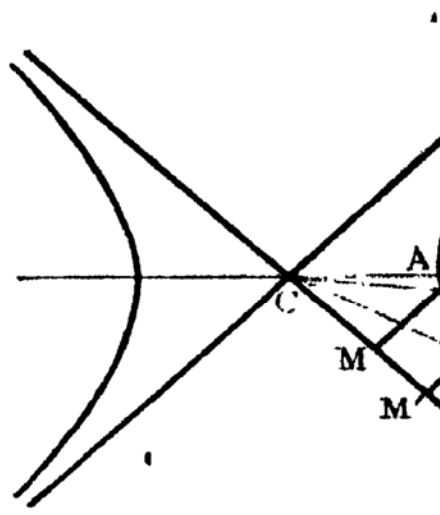

Fig. 25.

§ 56. *Area bounded by an Hyperbola and its Asymptot* equation of an hyperbola referred to its asymptotes is of th

$$xy = c^2.$$

Let CM′ (fig. 25) $= x_1$, CM $= x_2$, Q′M′ $= y_1$, Q M $= y_2$, then the angle between the asymptotes,

$$\text{area of } QMM'Q' = \int_{x_2}^{x_1} y\sin\alpha\,dx$$

$$= c^2\sin\alpha\int_{x_2}^{x_1}\frac{dx}{x} = c^2\sin\alpha\log_e\left(\frac{x_1}{x_2}\right) = c^2\sin\alpha\log_e\left(\frac{y_2}{y_1}\right)$$

since $x_1 = \frac{c^2}{y_1}$ and $x_2 = \frac{c^2}{y_2}$.

Now $c^2 = \frac{a^2 + b^2}{4}$ and $\sin\alpha = \frac{2ab}{a^2 + b^2}$, and therefore

$$(\alpha) \qquad \text{area} = \tfrac{1}{2}ab\log_e\left(\frac{x_1}{x_2}\right) = \tfrac{1}{2}ab\log_e\left(\frac{y_2}{y_1}\right).$$

Again, let MM′ $= x_1 - x_2 = p$, then

$$c^2 = x_1y_1 = x_2y_2 = \frac{py_1y_2}{y_2 - y_1}, \text{ therefore}$$

$$(\beta) \qquad QMM'Q' = \frac{py_1y_2}{y_2 - y_1}\log_e\left(\frac{x_1}{x_2}\right)\sin\alpha = \frac{py_1y_2}{y_2 \quad y_1}\log_e\left(\frac{y_2}{y_1}\right)\sin$$

Again, since

$$\tfrac{1}{2}x_1y_1\sin\alpha = \tfrac{1}{2}c^2\sin\alpha = \tfrac{1}{2}x_2y_2\sin\alpha,$$

we have triangle QCM = Q′CM′, and hence the sector QCQ′ = QMM′Q′.

The corresponding results for a rectangular hyperbola tained by substituting in the above formulæ $\frac{1}{2}a^2$ for c^2 a

Section III.—Plane Irregular, Rectilineal, and C lineal Figures.

A. *Irregular Rectilineal Figures.*

§ 57. The area of any irregular polygon can be found by it into triangles, trapeziums, &c., in the most convenient and adding together all the areas. For example,

ABCDEF (fig. 26) = CKB + BKHA + AHF + FGE + EGH

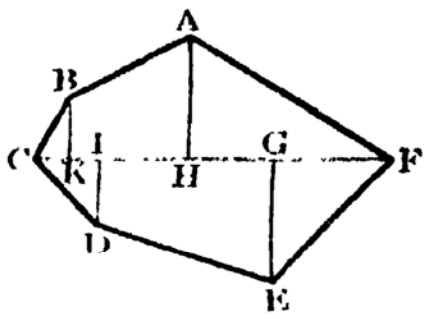

Fig. 26.

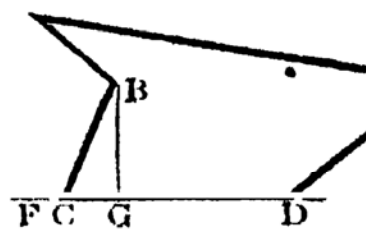

Fig. 27.

It may sometimes happen that some of the componen have to be subtracted instead of added; for example,

ABCDE (fig. 27) = AFHE + BCG − AFGB − EDH

§ 58. Again, the irregular rectilineal figure P_1P_2 . . . 28) can be broken up into a series of triangles and trape shown in the figure, and hence its area can be found.

§ 59. A figure made up of straight lines may be mea cutting it up into triangles by lines drawn from some one the others. For example (fig. 29),

ABCDEF = ABC + ACD + ADE + AEF.

polygon be concave some of the triangles will have to be ted.

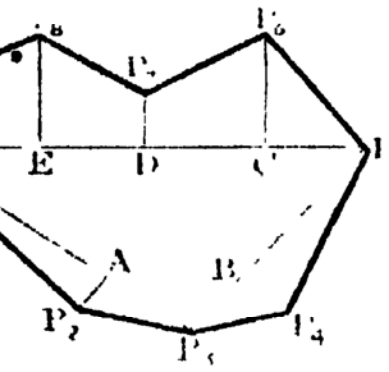

Fig. 28.

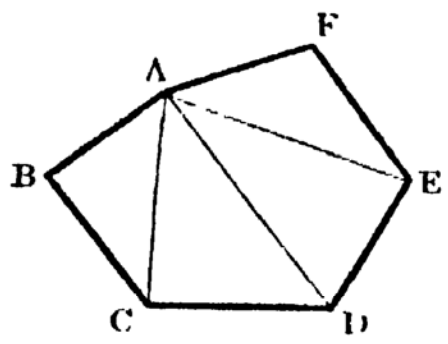

Fig. 29.

Area of a Polygon in terms of the Coordinates of its Angular — Let the coordi- P, Q, R (fig. 30) be (x_2, y_2), and (x_3, y_3) vely, and let the inclined at an angle w PL, QM, and RN to OY, then

OM $OL = x_2 - x_1$,

$ON - OM = x_3 - x_2$,

$ON - OL = x_3 - x_1$.

B. *Irregular Curvilineal Figures.*

Length of any Curve.—If we divide the given arc into an umber of intervals and re- ese as approximately circu- can find an approximation ength of the arc by means gens's formula, § 32. For , if we divide ABC (fig. 33) r parts in D, B, and E, and e chords AD, AB, DB, BE, EC, then

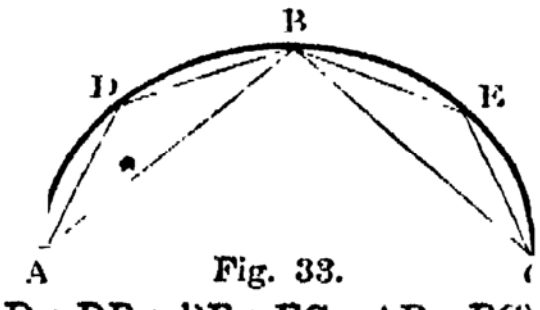

Fig. 33.

= AD + DB + BE + EC + ½(AD + DB + BE + EC − AB − BC)

nately.

For other methods of approximation, see Rankine's *R Tables.*

§ 63. *Area of an Irregular Curvilineal Figure.*—For ro proximations the following, called the trapezoidal method, used:

Divide A_1A_n (fig. 34) into n equal parts, and through th

P_{n-2} P_n,

A_1 A_2 A_{n-2} A_n

Fig. 34.

of division draw the ordinates, called by surveyors offset A_2P_2, &c.

Let $A_1P_1 = s_1$, $A_2P_2 = s_2$, &c., $A_nP_n = s_n$, and $A_1A_2 = A_2A_3 = \ldots = A_{n-1}A_n = a$.

Join P_1P_2, P_2P_3, &c., then the area of the polygon A_1A_nP

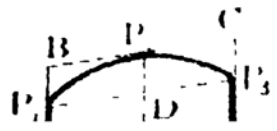
$= A_1A_2P_2P_1 + A_2A_3P_3P_2 + \ldots + A_{n-1}A_nP_nP_{n-1}$

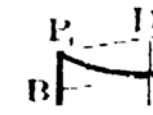
$= \frac{1}{2}a(s_1 + s_2) + \frac{1}{2}a(s_2 + s_3) + \ldots + \frac{1}{2}a(s_{n-1} + s_n)$ (§ 13, a

$= a\{\frac{1}{2}(s_1 + s_n) + s_2 + s_3 + \ldots + s_{n-1}\}$.

If we take n sufficiently great the difference between the the polygon and the curvilineal figure can be made as sma please, in other words, the smaller we make a the more ne will the above formula represent the area of the curvilineal

The curve may either be wholly convex or wholly concave to the line A_1A_n, or partly convex and partly concave.





§ 64. *Simpson's Rule.*—Let A_1A_n (fig. 34) be divided into an *even* number of equal parts, and as before through the points of division draw the ordinates A_1P_1, A_2P_2, &c.

Let $A_1A_3P_3P_1$ (figs. 35, 36) be a part of the figure thus divided, join P_1P_3, and through P_2 draw BC parallel to P_1P_3 to meet A_1P_1 in B and A_3P_3 in C.

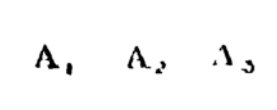


Fig. 35.

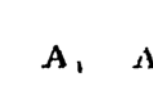

Fig.

Conceive a parabola to b through $P_1P_2P_3$ having its axis parallel to the ordinates, t

$A_1P_1P_2P_3A_3$ = trapezium $A_1P_1DP_3A_3$ + parabolic segment

$= a(s_1 + s_3) + \frac{1}{3}a\{s_2 - \frac{1}{2}(s_1 + s_3)\} = \frac{1}{3}a(s_1 + 4s_2 + s_3)$.

Now when the points P_1, P_2, P_3 are near each other the curve will coincide very nearly with the given curve; hence

$A_1P_1P_2P_3A_3 = \frac{1}{3}a(s_1 + 4s_2 + s_3)$ very nearly.

Similarly $A_3P_3P_5A_5 = \frac{1}{3}a(s_3 + 4s_4 + s_5)$, &c.;

hence whole area of figure

$= \frac{1}{3}a\{s_1 + s_n + 2(s_3 + s_5 + \ldots + s_{n-2}) + 4(s_2 + s_4 + \ldots +$

whence the rule: add together the two extreme ordinate the sum of the intermediate odd ordinates, and four times of the even ones, and multiply this result by one-third of the distance between the ordinates; the result is the area, *accu* the curved boundary be the arc of a parabola, in other proximately.

The curve may either be wholly convex or wholly concav line A_1A_n, or partly convex and partly concave, provide latter case the points of contrary flexure occur only at ordinates, for otherwise the intermediate arcs could not approximately parabolic. When points of contrary flexu ordinates may be drawn at these points, and the interme being found separately may be added to obtain the whole a

§ 65. In the two preceding sections we investigated two for approximating to the areas of curvilinear figures. proceed to consider the subject more generally.

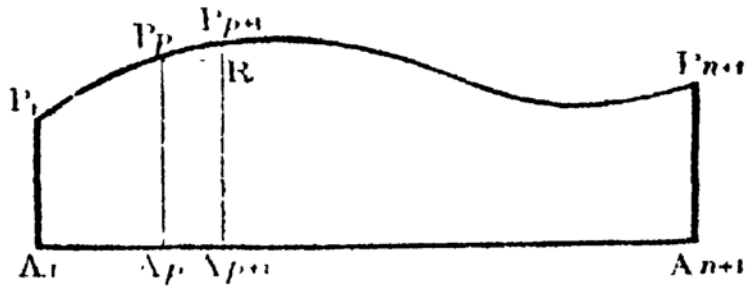

Fig. 37.

Let the equation to the curve $P_1P_pP_{n+1}$ (fig. 37) agree

$y = A + Bx + Cx^2 + \ldots + Kx^n$ for $n+1$ points between P_{n+1}, then the area of the curvilinear figure bounded by the lines A_1P_1, A_1A_{n+1}, and $A_{n+1}P_{n+1}$ and the curve P_1P_{n+1} ...ce very nearly with the curvilinear figure bounded by the ...aight lines and the curve whose equation is $y = A + Bx + \ldots + Kx^n$, and the greater the number of common points ...n will be the agreement

...A_{n+1} be divided into n equal parts, each equal to h, then ... nh. Now

$x = 0, \quad y = y_1 = A;$

$x = h, \quad y = y_2 = A + Bh + Ch^2 + \ldots + Kh^n$

$x = 2h, \quad y = y_3 = A + B\cdot 2h + C\cdot 2h^2 + \ldots + K(2h)^n;$

$\ldots\ldots\ldots\ldots\ldots\ldots$

$x = ph, \quad y = y_{p+1} = A + Bph + Cp^2h^2 + \ldots + K(ph)^n;$

$\ldots\ldots\ldots\ldots\ldots\ldots$

$x = nh, \quad y = y_{n+1} = A + Bnh + Cn^2h^2 + \ldots + K(nh)^n.$

...hese $n+1$ equations the $n+1$ quantities A, B, ... K ...letermined as functions of $y_1, y_2, \ldots y_{n+1}$, and h

... the area of the rectangle $A_pA_{p+1}P_pR = A_pA_{p+1} \cdot A_pP_p$.

$A_pP_p = y_p = A + B(ph) + C(ph)^2 + \ldots + K(ph)^n$

$A_pA_{p+1} = k = \frac{nh}{m}$

area of $A_pR = \left\{ A + B(ph)\frac{nh}{m} + C(ph)^2\frac{nh}{m} + \ldots + K(ph)^n\frac{nh}{m} \right\}\frac{nh}{m}$

$= \left\{ A + Bph\frac{n}{m} + Cp^2h^2\frac{n^2}{m^2} + \ldots + Kp^nh^n\frac{n^n}{m^n} \right\}\frac{nh}{m}$

of the whole figure

$= \sum_{p=0}^{p=m-1} \frac{nh}{m}\left\{ A + Bph\frac{n}{m} + Cp^2h^2\frac{n^2}{m^2} + \ldots + Kp^nh^n\frac{n^n}{m^n} \right\}$

$= \frac{nh}{m}\left\{ AS_0 + Bh\frac{n}{m}S_1 + Ch^2\frac{n^2}{m^2}S_2 + \ldots + Kh^n\frac{n^n}{m^n}S_n \right\},$

$S_n = 1^n + 2^n + 3^n + \ldots + m^n.$

...we take the limit of each of the terms

$\frac{S_0}{m}, \quad \frac{S_1}{m^2}, \quad \frac{S_2}{m^3}, \quad \ldots \quad \frac{S_n}{m^{n+1}}$

...curvilinear figure

$= nh\left\{ A + \frac{B}{2}nh + \frac{C}{3}n^2h^2 + \ldots + \frac{1}{n+1}n^nh^n \right\}.$

... this general result we can deduce "Simpson's Rule" and ...ther rule called "Weddle's Rule."

...let $n = 2$, that is, assume that the curve under consideration ...points in common with the curve whose equation is ...$Bx + Cx^2$, . . . , with a parabola, then

$y_1 = A,$
$y_2 = A + Bh + Ch^2,$
$y_3 = A + 2Bh + 4Ch^2.$

... area is approximately

$2h\left\{ A + B2h + \frac{4}{3}C2^2h^2 \right\}$

$\frac{1}{3}h\left\{ 6A + 6Bh + 8Ch^2 \right\}$

$= \frac{1}{3}h\left\{ y_1 + 4y_2 + y_3 \right\}$. Simpson's Rule.

...w put $n = 6$, we have area of curvilinear figure

$= h\left\{ A + \frac{1}{2}B6h + \frac{1}{3}C6^2h^2 + \frac{1}{4}D6^3h^3 + \frac{1}{5}E6^4h^4 + \frac{1}{6}F6^5h^5 + \frac{1}{7}G6^6h^6 \right\}.$

$y_1 = A,$

$y_2 = A + Bh + Ch^2 + \ldots + Gh^6,$

$\ldots\ldots\ldots\ldots\ldots$

$y_7 = A + B(6h) + C(6h)^2 + \ldots + G(6h)^6.$

...is system of equations we can determine A, B, C, . . . G, ...stituting the values so obtained in the above expression we ...he following remarkable formula for the approximate area:

area $= \frac{3}{10}h\left\{ (y_1 + y_3 + y_5 + y_7) + y_1 + 5y_2 + y_4 + y_6 \right\}$.

This formula, called Weddle's Rule, gives the closest approximation to the curvilinear area that can be obtained by any simple rule.

We are now in a position to find the approximate area of any irregular plane figure. For the given figure be divided into plane rectilinear and curvilinear figures, the areas of which can be separately determined by the rules already given. For example, APQRS (fig. 38)

$= ABC + APD + BRC - DQB - ASC.$

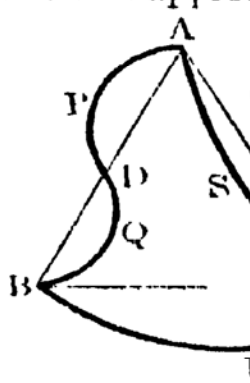

Fig. 38.

PART II. SOLIDS.

SECTION I. SOLIDS CONTAINED BY PLANES.

A. *Prisms, Parallelepipeds, and Prismatoids.*

§ 66. *Volume of a Right Prism.* First let the prism be a rectangular parallelepiped (fig. 39), and let the sole AB contain a units of length, BC b units of length, and CD c units of length. If we divide AB into a equal parts, BC into b equal parts, and CD into c equal parts, and if, through the points of division we draw planes parallel to the sides of the parallelepiped, these planes will divide it into a series of parallelepipeds whose edges are each equal to the unit of length. Each horizontal layer contains ab of these cubes, and since there are c layers the whole number of cubes will be abc. But each of these is the unit of volume, and

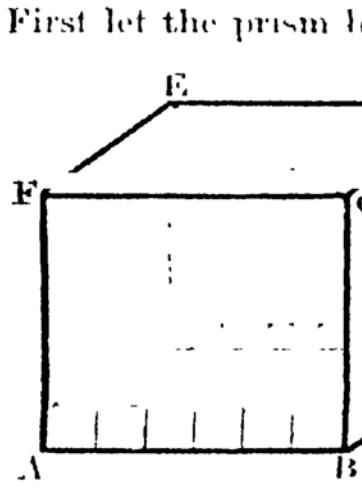

Fig. 39.

volume of ABCD $= abc = ab \times c =$ area of base ABC $\times$ altitude.

In the above demonstration we have assumed the edges commensurable, but from § 2 it follows that the proof will also when the edges are incommensurable. If the parallelepiped be cut by a plane BGE it will be divided into two equal triangular right prisms, and hence

volume of right triangular prism $= \frac{1}{2}ab \times c =$ area of its base $\times$ altitude.

Since every prism can be divided into triangular prisms as in fig. 40, we have at once

volume of right prism A'ABCDE = A'ABC + A'ACD + A'ADE
$= ABC \times BB' + ACD \times CC' + ADE \times DD'$
$= (ABC + ACD + ADE) \times$ altitude
(since $BB' = CC' = DD' =$ altitude)
= area of base ABCDE $\times$ altitude.

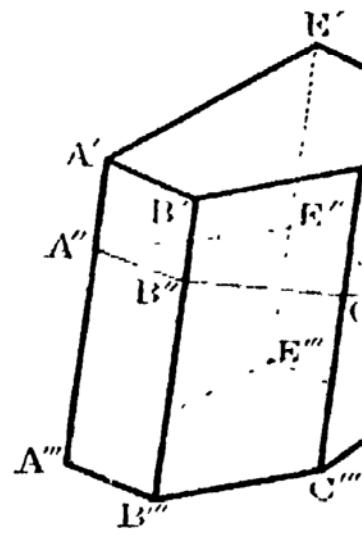

Fig. 41.

Fig. 40.

§ 67. *Volume of an Oblique Prism.*—Draw the right section A"B"C"D"E" (fig. 41), and let A' denote its area and A the area of the base A'B'C'D'E'. Let l denote the length of the prism or altitude, and α the angle between the planes A'B'C'D'E' and A"B"C"D"E".

Conceive the part above the right section placed at the other extremity of the prism. Then we have a right prism whose volume $= A' \times l$ (§ 66); but $A' = A\cos\alpha$, since A' is the projection of A (§ 51),

and $l = \frac{h}{\cos\alpha}$; hence

$$\text{volume} = A' \times l = A\cos\alpha \times \frac{h}{\cos\alpha} = A \times h;$$

or the volume of any prism is equal to the area of its base multiplied by its altitude.

Surface of a Prism.—Since the lines A″B‴, B″C‴, &c. (fig. ich make up the perimeter of the right section are all n ne perpendicular to the parallel edges AA‴, BB‴, &c., they pendicular to these edges and are therefore the altitudes of rallelograms A′B′B‴A‴, B′C′C‴B‴, &c., respectively. The surface of the prism is equal to the sum of these parallelo- and therefore

$$= A'A''' \cdot A''B'' + B'B'' \cdot B''C''' + \dots\dots$$
$$= A'A'''(A''B'' + B''C'' + \dots\dots),$$
$$A'A''' = B'B''' \text{ &c.};$$

lateral surface of any prism is equal to the perimeter of its ection multiplied by the length of the prism.

e prism be *right*, that is, if the faces be perpendicular to the hen its lateral surface is equal to the perimeter of its base lied by its length.

whole surface of any prism is obtained by adding to the surface the areas of its bases.

. If the prism be *regular*, that is, if the bases be regular ns, then

$$\text{base} = a^2 \times \frac{n}{4} \cot\frac{180^\circ}{n} \text{ (§ 18, } \gamma\text{)}, \text{ where } n \text{ is the number}$$

s each of length a, and therefore

$$\text{volume} = a^2 \times \frac{n}{4} \cot\frac{180^\circ}{n} \times h,$$

h is the altitude of the prism.

in, if the prism be right and regular, then

$$\text{its lateral surface} = nah + 2a^2 \times \frac{n}{4} \cot\frac{180^\circ}{n}$$

. *Volume of a Pyramid.* Let VABC (fig. 42) be for sim- a triangular pyramid. Divide VA into n equal portions, and h the points of section draw parallel to the base ABC, and h BC and through the inter- s of these planes with VBC draw parallel to VA. Let h denote itude of the pyramid, then the o of the base of the r^{th} prism he vertex V

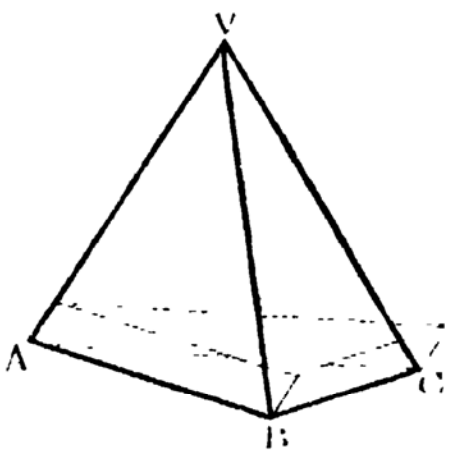

Fig. 42.

$$= r^2 \times \frac{h}{n^3},$$

A denote the area of ABC, we

$$\frac{\text{base of } r^{th} \text{ prism}}{A} = \frac{r^2h^2}{n^3} \times \frac{1}{h^2} = \frac{r^2}{n^3},$$

by a well-known theorem in solid ry, the areas of sections of a pyramid made by planes parallel base are proportional to the squares of their altitudes. s we have

$$\text{base of } r^{th} \text{ prism} = \frac{r^2}{n^2} A, \text{ and therefore}$$

$$\text{its volume} = \frac{r^2}{n^2} A \times \frac{h}{n} \text{ (§ 67)}$$

$$= \frac{hA}{n^3} \times r^2.$$

ore volume of whole pyramid

$$= hA \prod_{n=\infty} \frac{1^2 + 2^2 + \dots + r^2 + \dots + n^2}{n^3}$$

$$= hA \prod_{n=\infty} \frac{n(n+1)(2n+1)}{6n^3} = \frac{hA}{3}$$

volume of any pyramid is equal to one-third of the area of its ultiplied by its height.

n this we see that pyramids on equal bases are to one another r altitudes.

e pyramid be *regular*, that is, if its base be a regular polygon rpendicular through whose centre passes through the vertex,

$$\text{its volume} = \frac{1}{3} \cot\frac{180^\circ}{n} \cdot h^3.$$

Surface of a Regular Pyramid.—The lateral surface of the pyramid VABCDEF (fig. 43) is equal to the sum of the areas n congruent triangles which make up the lateral surface of ramid.

area of triangle VAB = $\frac{1}{2}$AB × VG; hence whole lateral sur- $\frac{1}{2}n$AB·VG = $\frac{1}{2}nal$, where l is the slant height and a the length side of the base.

n, if VO = h = altitude of pyramid, we have

$$l = VG = \sqrt{VO^2 + OG^2} = \sqrt{h^2 + \frac{a^2}{4} \cot^2\frac{180^\circ}{n}},$$

therefore whole surface = base + lateral surface

$$= a^2 \times \frac{n}{4} \cot\frac{180^\circ}{n} + \frac{1}{2}na\sqrt{h^2 + \frac{a^2}{4} \cot^2\frac{180^\circ}{n}}$$

$$= \frac{1}{2}na\left(\frac{a}{2} \cot\frac{180^\circ}{n} + \sqrt{h^2 + \frac{a^2}{4} \cot^2\frac{180^\circ}{n}}\right).$$

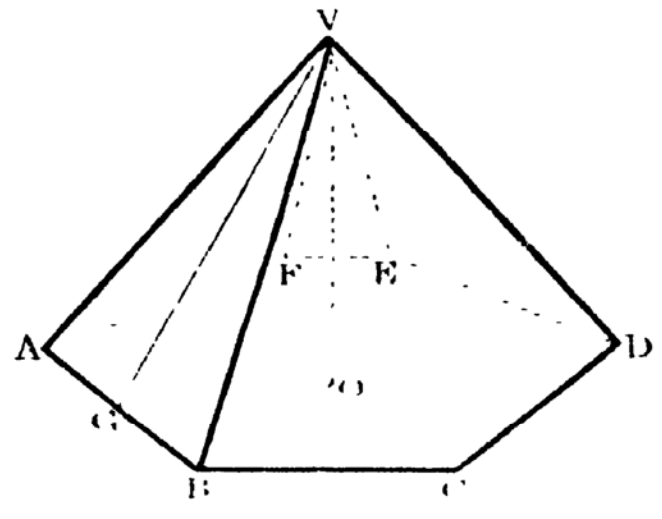

Fig. 43.

§ 72 *The Prismatoid.* If we have a polyhedron whose two polygons in parallel planes, the number of sides in ea the same or different, and if we so join the vertices of the that each line in order forms a triangle with the preceding line and one side of either base, the figure so formed is called a "prismatoid," and holds in stereometry a position similar to that of the trapezium in planimetry. To make the investigation of the volume of the prismatoid as simple as possible, we take the case where the lower base is a polygon of four and the upper one of three sides.

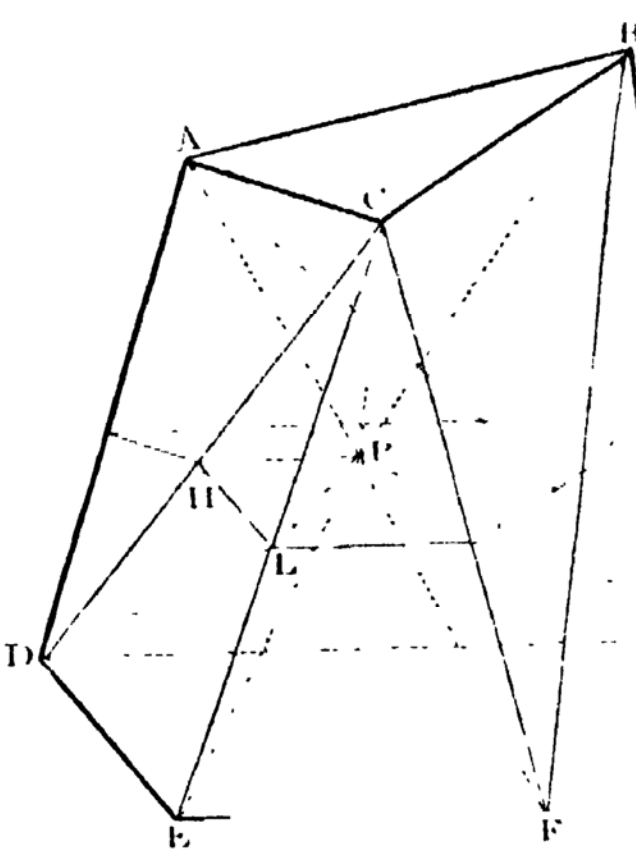

Fig. 44.

Let ABCDEFG (fig. 44) be the prismatoid, of which ABC or A_1 is the upper and DEFG or A_3 the lower base, and let HLM be the section equidistant from the bases. Take any point P section and join it to the corners of the prismatoid. divide the polyhedron into two pyramids PABC and and a series of polyhedra of which CPDE may be tak specimen.

Let h be the altitude of the prismatoid, then $\frac{1}{2}h$ is the al each of the pyramids PABC, PDEFG, and hence

$$\text{volume of PABC} = \tfrac{1}{6}hA_1, \text{ and}$$
$$\text{volume of PDEFG} = \tfrac{1}{6}hA_3.$$

Again join PH, PL, and LD, then

$$\text{volume of CPDE} = 2 \text{ volume of CPDL},$$
$$\text{since DE} = 2\text{HL},$$
$$\text{and volume of CPDL} = 2 \text{ volume of CPHL},$$
$$\text{hence volume of CPDE} = 4 \text{ volume of CPHL}.$$

Now volume of CPHL = $\frac{1}{6}h \times$ area of HLP, and therefo of CPDE = $\frac{2}{3}h \times$ area of HLP.

Similarly the volume of every such polyhedron is $\frac{2}{3}h \times$ of its own portion of the middle section. Hence if A_2 de area of the middle section we have

$$\text{volume of prismatoid} = \tfrac{1}{6}hA_1 + \tfrac{1}{6}hA_3 + \tfrac{2}{3}hA_2$$
$$= \tfrac{1}{6}h(A_1 + 4A_2 + A_3).$$

§ 73. *Volume of the Frustum of a Pyramid.* Let A′A″B (fig. 45) be a frustum of the pyramid VA′B′C′, and let A denote the areas of the ends A′B′C′, A″B″C″ respective VP = x = altitude of pyramid VA″B″C″, and let PQ = h = al frustum.

Now $\frac{A_2}{A_1} = \frac{x+h}{x}$, whence $x = \frac{h\sqrt{A_1}}{\sqrt{A_2} - \sqrt{A_1}}$.

frustum = VA′B′C′ − VA‴B‴C‴

$$= \tfrac{1}{3}\{A_1(c+h) \quad A_3 c\}$$

$$\left\{ A_1\left(\begin{matrix} h\sqrt{A_1} \\ \sqrt{A_1}-\sqrt{A_3}\end{matrix}\right) \quad A_3\left(\begin{matrix} h\sqrt{A_3} \\ \sqrt{A_1}-\sqrt{A_3}\end{matrix}\right)\right\}$$

$$= \tfrac{1}{3}h(A_1 + \sqrt{A_1 A_3} + A_3);$$

a which applies to the frusta of all pyramids regular and

bove result may be otherwise expressed. For, let $A'B' = a_1$ $A'''B''' = a_3$, then, if $A''B''C''$ be a section equidistant from the the frustum, $A''B'' = a_2 = \tfrac{1}{2}(a_1 + a_3)$.

$A_1 = pa_1^2$ and $A_3 = pa_3^2$ (see § 70);

A_2 = area of $A''B''C''$ $= pa_2^2 = p\left(\frac{a_1+a_3}{2}\right)^2$, which gives

$$4A_2 = pa_1^2 + 2pa_1a_3 + pa_3^2 \quad A_1 + 2\sqrt{A_1A_3} + A_3;$$

e volume of frustum

$$= \tfrac{1}{6}h(2A_1 + 2\sqrt{A_1A_3} + 2A_3) = \tfrac{1}{6}h(A_1 + 4A_2 + A_3);$$

olume of the frustum of a pyramid is obtained by adding as of the ends to four he area of the middle and multiplying the one-sixth of the alti-

above result can be ob- at once from § 72, since ‴B‴C‴ is a prismatoid nilar bases.

Surface of the Frustum ular Pyramid. In fig. the perimeter of A_1 p_1, A_2 p_2, and that of and let $VD' = l_1$, l_3, and therefore $D'D'''$ $VD''' = l_1 \quad l_3 \quad l$. The surface of the frustum is the difference between the lateral surfaces of the pyramids ′ and VA‴B‴C‴,

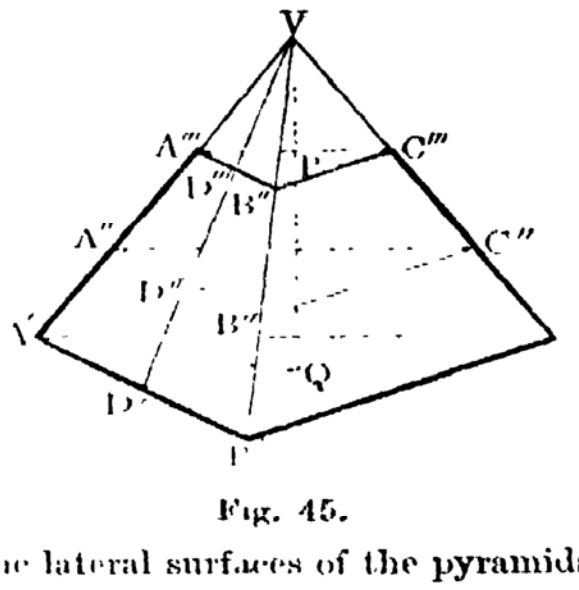

Fig. 45.

$$\tfrac{1}{2}p_1 l_1 \quad \tfrac{1}{2}p_3 l_3.$$

nce $\frac{l}{l_3} = \frac{a_1}{a_3} = \frac{ma_1}{ma_3} = \frac{p_1}{p_3}$, we have $l_1 = \frac{p_1 l}{p_1 - p_3}$ and $l_3 = \frac{p_3 l}{p_1 - p_3}$,

re lateral surface of frustum

$$= \tfrac{1}{2}l\left(\frac{p_1^2 - p^2}{p_1 - p_3}\right) \qquad p_1 + p \qquad lp_2;$$

lateral surface of the frustum of a regular pyramid is equal product of the slant height and the perimeter of the section tant from the ends.

wise. The top and base being regular polygons, the inclined are congruent trapeziums. Let l be the height of each um, and let there be n of them, then

$$\text{area of each face} = \frac{l}{2}(p_1 + p_3),$$

herefore the area of lateral surface $= \frac{l}{2}(p_1 + p_3) = lp_2$.

If h the altitude of the frustum be given, we deduce the height and then proceed as before. Thus let $VP = h_3$, , and using the same notation as in §§ 72, 73, and 74 we

$$\frac{h_1}{h_1 - h_3} = \frac{a_1}{a_1 - a_3}, \text{ which gives } h_1 = \frac{a_1(h_1 - h_3)}{a_1 - a_3}, \quad \frac{a_1 h}{a_1 - a_3}.$$

$$l, \qquad \text{of } 180°, \text{ and } l = \left(\qquad\right) l,$$

l is known since l_1 is known in terms of h

n the pyramid is irregu- lateral planes are non- ent trapeziums, the areas of can be found separately by nd hence the whole surface.

Volume of the Frustum of angular Prism.—Let A denote ea of ABC (fig. 46), and let , h_3 be the altitudes of A′, respectively with reference to ne ABC. Divide the frustum ree pyramids B′A′AC, B′ABC, A′ACC′ by the planes B′AC′ A′AC. These three pyramids spectively equal to BA′AC, , and ABCC′;

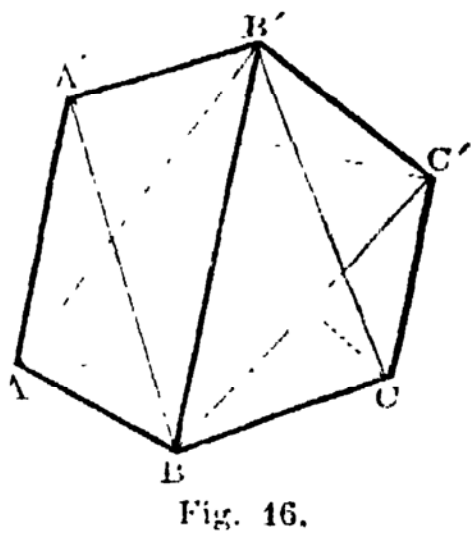

Fig. 46.

volume of frustum $= \tfrac{1}{3}h_1 A + \tfrac{1}{3}h_2 A + \tfrac{1}{3}h_3 A$

$$= \tfrac{1}{3}A(h_1 + h_2 + h_3).$$

§ 77. If the prism be right or oblique, the volume of a frus equal to one-third of the area of its right section multiplied sum of the parallel edges. For divide the frustum AA′B′ 47) into two frusta by a plane A″B″C″ of area A at right to the edges, then

AA′B′C′ = AA″B″C″ + A″A′B′C′

$= \tfrac{1}{3}A(AA'' + BB'' + CC'') + \tfrac{1}{3}A(A'A'' + B'B'' + C'C'')$

$= \tfrac{1}{3}A(AA'' + BB'' + CC'' + A'A'' + B'B'' + C'C'')$

$= \tfrac{1}{3}A(AA' + BB' + CC'')$.

Again, since every prism can be divided into triangular we can find by repeated applications of the above proposit volume of the frustum of any prism whatever. For exar

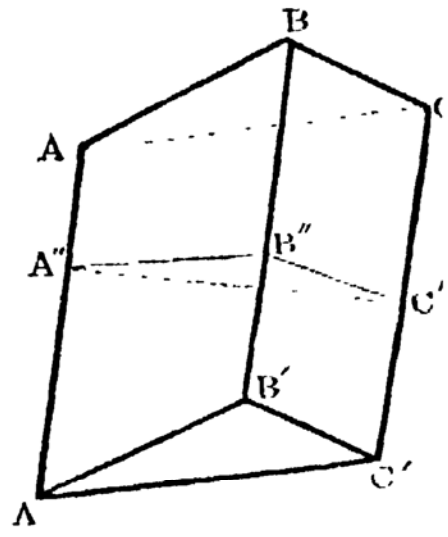

Fig. 47

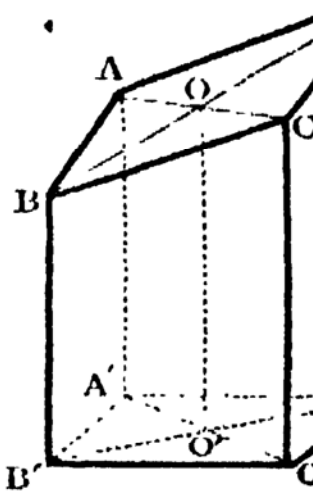

Fig. 48.

the base of the frustum of a right prism AA′B′C′D′ (be a rectangle 12 feet by 6 feet, and the parallel edges i 6, 4, 10, and 12 feet, then

A = area of base $= 12 \times 6 = 72$ square feet.

Frustum = ABCA′B′C′ + ADCA′D′C′

$= \frac{1}{3} \times \frac{1}{2}A(AA' + BB' + CC') + \frac{1}{3} \times \frac{1}{2}A(AA' + CC' + DD')$

$\frac{1}{6}A(2AA' + 2CC' + BB' + DD') = 576.$

§ 78. *Volume of a Wedge.* The wedge (fig. 49) being merely the frustum of a triangular prism, we have at once

volume $= \frac{1}{3}A(FE + AD + BC)$,

where A is the area of its right section; otherwise, the wedge may be considered a prismatoid whose upper base is a straight line, and hence its volume $= \frac{1}{6}h(4A_2 + A_3)$, since A

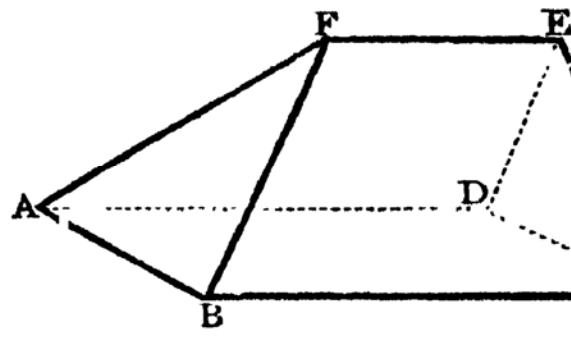

Fig. 49.

B. *Regular Polyhedra.*

§ 79. The regular polyhedra are five in number, nam *tetrahedron*, *cube*, *octahedron*, *dodecahedron*, and *icosahedro* solid angles are formed respectively by three equilateral t three squares, four equilateral triangles, three pentagons, equilateral triangles.

Since a regular polyhedron admits of having a sphere i within it and described about it, it can easily be shown volume of the polyhedron

$$= a^3 \times \frac{nl}{24} \times \frac{\cos\frac{\pi}{m}\cot^2\frac{\pi}{n}}{\left\{1 - \cos\left(\frac{\pi}{m}+\frac{\pi}{n}\right)\cos\left(\frac{\pi}{m}-\frac{\pi}{n}\right)\right\}^{\frac{1}{2}}};$$

and from § 18, γ, it follows that the surface of the polyhed

$$= a^2 \times \frac{ln}{4}\cot\frac{\pi}{n},$$

where l = the number of faces,
m = the number of faces in each solid angle,
n = the number of edges in each face,
and a = the length of each side.

The following table contains the surfaces and volumes five regular polyhedra whose edge is 1.

Polyhedron.	Surface.	Volume.
Tetrahedron	1·7320508	0·117851
Cube	6·0000000	1·000000
Octahedron	3·4641016	0·471404
Dodecahedron	20·6457788	7·663118
Icosahedron	8·6602540	2·181695

face and volume of a regular polyhedron whose edge is
ined by multiplying the surface and volume of a similar
on whose edge is 1 by a^2 and a^3 respectively

s II. Solids contained by Surfaces which are not all Planes

A. *The Cylinder*

Volume of a Cylinder (fig. 50). Inscribe in the cylinder a
l prism of which the number of sides may be increased
ely. Then in the limit the base of the prism becomes the
he cylinder, and the volume of the prism the volume of
der. Now by § 67 we have

volume of prism = area of base × altitude;
volume of cylinder = area of base × altitude.

Surface of a Right Cylinder.—As above, in the limit the
he prism becomes the base of the cylinder, and the surface
rism the surface of the cylinder. Now the lateral surface

meter of right section × length
meter of base × length, in the case of a right prism (§ 68)
ateral surface of right cylinder = circumference of base
.

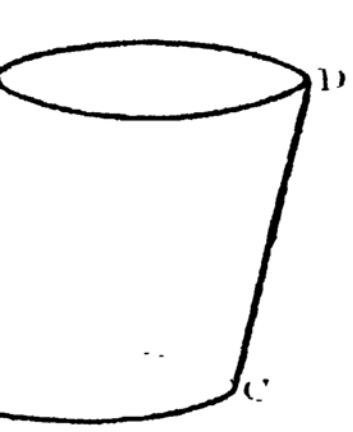

Fig. 50.

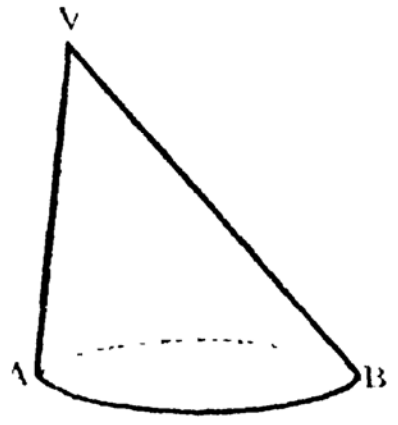

Fig. 51.

B. *The Cone.*

Volume of a Cone (fig. 51). Inscribe within the cone a
l of which the number of sides may be indefinitely
then in the limit the base of the pyramid becomes the base
one and the volume of the pyramid the volume of the cone.

volume of pyramid = ⅓ base × altitude,
ce volume of cone = ⅓ base × altitude.

Volume of the Frustum of a Cone.—From § 73 we find that
me of the frustum of a pyramid

$$\tfrac{1}{3}h(A_1 + \sqrt{A_1A_3} + A_3),$$

nce in the limit the frustum of the pyramid becomes the
of the cone, we have

volume of conical frustum $= \tfrac{1}{3}h(A_1 + \sqrt{A_1A_3} + A_3)$,

A_1 and A_3 are the areas of the terminating planes of the

he terminating planes be circles of radii r_1 and r_3, then
of frustum

$$= \tfrac{1}{3}h(\pi r_1^2 + \pi r_1 r_3 + \pi r_3^2) = \tfrac{1}{3}\pi h(r_1^2 + r_1 r_3 + r_3^2).$$

, by the same section we have

volume of frustum of pyramid $= \tfrac{1}{6}h(A_1 + 4A_2 + A_3)$,
e volume of conical frustum $= \tfrac{1}{6}\pi h(r_1^2 + 4r_2^2 + r_3^2)$,

r_2 is the radius of the circular section parallel to the ter-
g planes and equidistant from them.

Surface of a Right Cone.—The lateral surface of a regular
l is by § 71

½ perimeter of base × slant height;

nce in the limit the surface of the pyramid becomes the sur-
the cone, the lateral surface of a right cone is equal to half
umference of its base multiplied by the slant height.

the lateral surface of a right cone of slant height l and the
f whose base is r is equal to

$$\tfrac{1}{2} \times 2\pi r \times l = \pi r l,$$

whole surface = lateral surface + area of base
$= \pi r l + \pi r^2$
$= \pi r(l + r)$.

, if h, the altitude of the cone, be given, we have

$$l = \sqrt{h^2 + r^2},$$

refore whole surface $= \pi r(\sqrt{h^2 + r^2} + r)$.

Surface of the Frustum of a Right Cone.—The lateral surface
frustum of a regular pyramid is equal to the product of th
eight and the perimeter of its middle section (§ 74); hence
in the limit we find that the lateral surface of the frustum
right cone is equal to the product of its slant height and t
umference of the section equidistant from its parallel fac

Let r_1 and r_3 denote the radii of the ends of the frustum
the length of the slant height, then

$r_2 = \tfrac{1}{2}(r_1 + r_3)$ = radius of middle section,

and therefore

lateral surface $= 2\pi r_2 l = 2\pi \cdot \tfrac{1}{2}(r_1 + r_3) \cdot l = \pi l(r_1 + r_3)$,

and whole surface $= \pi r_3 + \pi l(r_1 + r_3) + \pi r_1^2$.

If h, the altitude of the frustum, be given, we have

$$l = \sqrt{h^2 + (r_1 - r_3)^2}.$$

C. *The Sphere.*

§ 86. *Surface of a Spherical Zone.* Let AB (fig. 52) be a small arc of the sphere, and let AA′, BB′ be perpendicular to the axis AA′ to find the surface of the zone generated by the arc AB. Join AB, and draw OP perpendicular to AB, BD parallel to AA′, and PP′ parallel to AA′ or BB′. The chord AB generates the frustum of a cone, whose lateral surface $= 2\pi PP' \cdot AB$.

But, since the triangles ABD and OPP′ are similar,

AB : OP = BD : PP′.

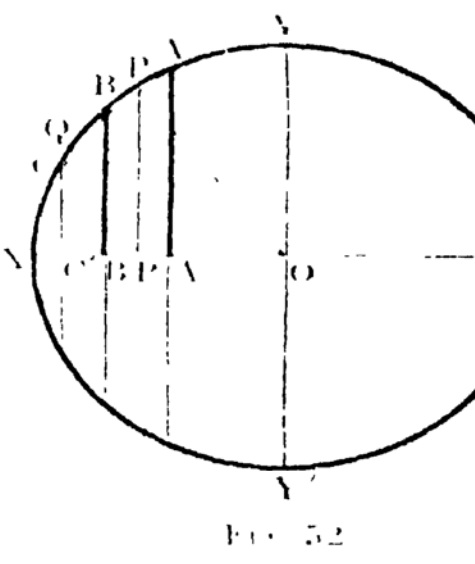

Fig. 52.

therefore area of conical frustum $= 2\pi \cdot OP \cdot BD = 2\pi \cdot OP \cdot AA'$.
Similarly the area of the frustum generated by BC $= 2\pi \cdot OQ \cdot$

But in the limit when the chords AB, BC, &c., are indefinitely diminished, the perpendiculars OP, OQ, &c., become each
hence by summing all the areas we get in the limit

area of zone $= 2\pi r \times$ projection of arc on axis of revolution.

Hence the convex surface of a segment of a sphere is equal
circumference of a great circle multiplied by the height of t
ment or zone.

§ 87. *Surface of a Sphere.* The whole sphere is one
whose height is $2r$, we obtain at once

surface of sphere $= 2\pi r \cdot 2r = 4\pi r^2$,

or the surface of a sphere is equal to four great circles.

The total surface of the cylinder circumscribing the sp
radius r is $6\pi r^2$, hence the surface of the sphere = ⅔ surface
circumscribing cylinder.

§ 88. *Surface of a Lune, a Spherical Triangle, and a Sp
Polygon.* It is shown in spherical trigonometry that

(α) the area of a lune included between two great cir
sphere of radius r, and whose inclination is θ radians

$= 2\theta r^2$;

β) the area of a spherical triangle whose angles are A, B
$= (A + B + C - \pi)r^2$,

) spherical polygon of n sides is
$= \{P - (n-2)\pi\}r^2$, where P = the sum of its angles

§ 89. *Measurement of Solid Angles.* A convenient unit
measurement of plane angles is the "radian." If we a su
h unit of surface of a sphere subtends the same solid ang
centre, we can deduce a very convenient unit for the meas
of solid angles. The unit, which has received the name
dian," we define to be the solid angle subtended at the cen
sphere by a portion of the surface whose area is r^2.

§ 90. *Value of Steradians in any Angle.* Let A be the
the centre of a sphere, and let S be the portion of the surfa
sphere which it intercepts, then

number of steradians in A $= \dfrac{S}{r^2}$.

For example, if A be a plane solid angle, S a hem
$2\pi r$; hence the number of steradians
in a plane solid angle $= \dfrac{S}{r^2} = \dfrac{2\pi r}{r} = 2\pi$,

and therefore the number of steradians in
the solid angle at a point $= 4\pi$. This solid
angle is sometimes called a "sphere."

Hence, if we can find the surface in
tended by any solid angle, we can alw
find its magnitude in terms of the u
solid angle.

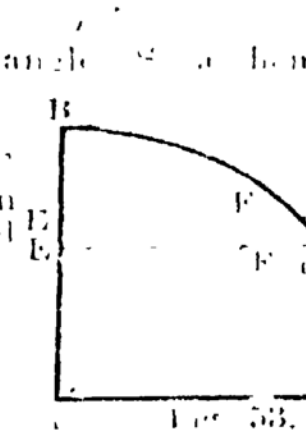

Fig. 53.

Volume

(fig. 53) be the quadrant of a circle, draw DB and DC tang
it, then, if AD be joined and the whole figure be conce

round AB, ABD, ABC, and ABDC will generate a cone, sphere, and a cylinder respectively.

draw two parallel planes EFGH and E′F′G′H′ very near each d perpendicular to AB, and draw EE′ and GG′ parallel to n, by § 80,

olume generated by LHH′L′ πEH² − EE′,
EGG′E′ πEG² − LE′,
EFF′E′ πEF² − LF².

lume generated by EFF′E′ + volume generated by EGG′E′
π(EF² + EG² − LE′ = πEA′ · EG² − EE′
π(AG² − EE′ = πLH² − LL′
volume generated by LHH′L′

n the limit, when the number of frustums indefinitely increased and their thickness indefinitely diminished, we have volume generated by AF = volume of spherical zone generated by CG = volume of cylinder generated by CH.

radius of sphere, h = AL = height of zone ACGE, then

volume of cone = $\frac{1}{3}\pi h^3$ · h = $\frac{1}{3}\pi h^3$, and
volume of cylinder = $\pi r^2 \cdot h$,
volume of spherical zone = $\pi r^2 h - \frac{1}{3}\pi h^3$
= $\frac{1}{3}\pi h(3r^2 - h^2)$.

eight of a hemisphere is r,

volume of hemisphere = $\frac{1}{3}\pi r \cdot 3r^2 - r^3$ = $\frac{2}{3}\pi r^3$,
volume of whole sphere = $\frac{4}{3}\pi r^3$,

readily obtainable by the infinitesimal calculus, or by ng within the sphere a series of triangular pyramids whose all meet at the centre of the sphere, and the angles of whose l rest on the surface. In the limit the altitude of each becomes the radius of the sphere, and the sum of the bases yramids the surface of the sphere; hence

volume = $\frac{1}{3}S \cdot r$ = $\frac{1}{3} \cdot 4\pi r^2 \cdot r = \frac{4}{3}\pi r^3$.

ume of the circum-cribing cylinder = $\pi r^2 \cdot 2r = 2\pi r^3$,
e volume of sphere = $\frac{2}{3}$ volume of circumscribing cylinder.

Let S denote the surface of a sphere and V its volume, then 87 and 91 we have

$$(\alpha)\quad r = \frac{S}{2\sqrt{\pi}}\sqrt{\frac{S}{4\pi}} = \sqrt[3]{\frac{3}{4\pi}}\cdot\sqrt[3]{V};$$

$$(\beta)\quad S = \sqrt{\pi}\sqrt[3]{6V}\cdot\sqrt[3]{V},$$

$$= \frac{1}{6\sqrt{\pi}}\sqrt{S^3}$$

which give the radius in terms of the surface or volume, the in terms of the volume, and the volume in terms of the

Volume of a Spherical Shell.—Let r and r_1 denote the radii wo spheres, then

volume of shell V = $\frac{4}{3}\pi r_1^3 - \frac{4}{3}\pi r^3$
= $\frac{4}{3}\pi(r_1^3 - r^3)$
= $\frac{4}{3}\pi r_1 - r)(r_1^2 + r_1 r + r^2)$.

t $r_1 - r = h$, then

$$V = \frac{4}{3}\pi r_1^3 h\left(1 + \frac{r}{r_1} + \frac{r^2}{r_1^2}\right)$$

small compared with r_1, then r/r_1 is very nearly equal to 1, have approximately

$V = \frac{4}{3}\pi r_1^3 h(1 + 1 + 1) = 4\pi r_1^2 h$.

t h be nearly equal to r_1, r is very small, and r/r_1 is also very so that we have approximately

$V = \frac{4}{3}\pi r_1^2 h$.

Volume of a Spherical Segment.—Let CRC (fig. 54) be a of a spherical segment wh RQ is p, then, if OQ = h, of segment CRC = volume of here = volume of zone VVC′C

$= \frac{1}{3}\pi h\{3r^2 - h^2\}$, § 91
$= \frac{1}{3}\pi(r - p)\{3r^2 + (r - p)^2\}$
$= p^2(3r - p)$.

ut $p = 2r$, we obtain as before of sphere = $\frac{4}{3}\pi r^3$
t CQ = r_1 we have
r_1 = RQ.EQ = $p(2r - p)$

whence $r = \frac{r_1^2}{2p} + \frac{p}{2}$,

re volume of segment = $\frac{1}{3}\pi p^2(3r_1 + p^2)$.

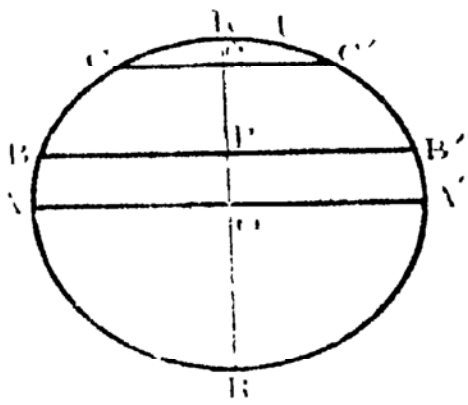

Fig. 54.

Volume of a Spherical Frustum.—When one of the terminating planes passes through the centre we have already that the volume

$= \frac{1}{3}\pi h(r^2 + h^2)$,

where h is its altitude.

Now suppose that neither of the terminating planes passes the centre; for example, to find the volume of the frustum

Let RQ = p and RP = q, then

BB′C′C = segment RBB′ − segment RCC′
$= \frac{1}{3}\pi q(3a_2^2 + q^2) - \frac{1}{3}\pi p(3a_1^2 + p^2)$,

where a_1 and a_2 are the radii of the ends CC′ and BB′.

Let $q - p = h$ = height of frustum, and, since, from the geo the figure,

$$\frac{a_1^2 + p^2}{p} = \frac{a_2^2 + q^2}{q} = 2r,$$

we have volume = $\frac{1}{6}\pi h\{3(a_1^2 + a_2^2) + h^2\}$,

a result which may also be obtained by considering BB′C′C difference of the two zones AA′C′C and AA′B′B.

D. *Spheroid.*

§ 96. *Surface of a Prolate Spheroid.*—The prolate sphero solid generated by the revolution of an ellipse about its ma If S be the surface generated by an arc of the curve, then

$S = 2\pi\int y\sqrt{1 + \left(\frac{dy}{dx}\right)^2}dx$, taken between proper lim

In the case before us

$S = 2\pi b^2 + 2\pi\frac{ab}{e}\sin^{-1}e$,

where e is the eccentricity (INFINITESIMAL CALCULUS, art.

§ 97. *Surface of an Oblate Spheroid.*—The oblate sphero solid generated by the revolution of an ellipse about its m (fig. 55).

Here surface = $2\pi a^2 + \pi\frac{b^2}{e}\log_e\frac{1+e}{1-e}$ (INFINITESIMAL CA art. 179).

§ 98. *Volume of a Spheroid.*—We have volume of prolate

$$\pi\int_{-a}^{+a} b^2\left(1 - \frac{x^2}{a^2}\right)dx = 2\pi b^2\int_0^a\left(1 - \frac{x^2}{a^2}\right)dx = \frac{4}{3}\pi ab^2$$

Similarly volume of oblate spheroid = $\frac{4}{3}\pi a^2 b$.

Thus,

$$(\alpha)\quad \frac{\text{volume of prolate spheroid}}{\text{volume of oblate spheroid}} = \frac{\frac{4}{3}\pi ab^2}{\frac{4}{3}\pi a^2 b} = \frac{b}{a};$$

$$(\beta)\quad \frac{\text{sphere described on major axis}}{\text{prolate spheroid}} = \frac{\frac{4}{3}\pi a^3}{\frac{4}{3}\pi ab^2} = \frac{a^2}{b^2};$$

$$(\gamma)\quad \frac{\text{sphere described on minor axis}}{\text{oblate spheroid}} = \frac{\frac{4}{3}\pi b^3}{\frac{4}{3}\pi a^2 b} = \frac{b^2}{a^2}.$$

§ 99. *Volume of a Segment of a Spheroid.*

(α) *The prolate spheroid.*—This segment is generated revolution of AMP (fig. 23, p. 20) about AM, and hence

its volume = $\pi\int_0^h y^2dx = \pi\frac{b^2}{a^2}\int_0^h(2ax - x^2)dx = \frac{\pi}{3} \times \frac{b^2h^2}{a^2}(3$

where A is the origin and AM = h.

(β) *The oblate spheroid.* The segment in this case is g by the revolution of BMP (fig. 55) about BC, and hence

its volume = $\pi\int_0^h y^2dx = \pi\frac{a^2}{b^2}\int_0^h(2bx - x^2)dx = \frac{\pi}{3} \times \frac{a^2h^2}{b^2}(3$

where B is the origin and BM = h.

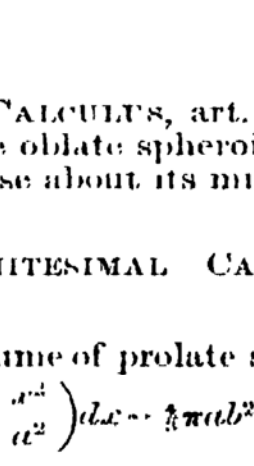

Fig. 55

§ 100. *Volume of the Frustum of a Spheroid when one of the Terminating Planes passes through the Centre.*

(α) *The prolate spheroid.* The frustum in this case is generated by the revolution of BCMP about CM (fig. 23).

Now volume generated by BCMP
= volume generated by BCA
− volume generated by PMA

$$\frac{2}{3}\pi ab^2 - \frac{b^2h^2}{a}(3a - h)$$

$$= \frac{\pi}{3}\frac{b^2k}{a^2}(3a^2 - k^2), \text{ where}$$

k = CM = height of frustum = $a - h$.

(β) *The oblate spheroid.*—We can show in a similar that the volume generated in this case

$$= \frac{\pi}{3} \times \frac{a^2k}{b^2}(3b^2 - k^2).$$

The above formulæ may be put into another form. Thu case of the prolate spheroid, since the point P lies on t $b^2x^2 + a^2y^2 = a^2b^2$, we have

$b^2k^2 + a^2b_1^2 = a^2b^2$, where b_1 = PM, which gives

$$k^2 = a^2\frac{(b^2 - b_1^2)}{b^2};$$

by substitution, the volume of prolate frustum
$$= \tfrac{1}{3}\pi k(2b^2 + b_1^2).$$
y we can show that the volume of the oblate frustum
$$= \tfrac{1}{3}\pi k^2(2a^2 + a_1^2),$$
where a_1 = PM.

rmulæ play an important part in the gauging of casks.

E. *Paraboloid.*

Surface of a Paraboloid. - Let the equation to the para $y^2 = 4ax$, and let the coordinates of P (fig. 21, p. 19) be x_1, the surface of the paraboloid generated by the revolution bout AP
$$2\pi\int_0^{x_1} y\sqrt{1+\left(\frac{dy}{dx}\right)^2}dx = 4\pi\sqrt{a}\int_0^{x_1}\sqrt{x}\sqrt{x+a}\,dx$$
$$= \tfrac{8}{3}\pi\sqrt{a}\left\{(x_1+a)^{\frac{3}{2}} - a^{\frac{3}{2}}\right\}.$$

Volume of a Paraboloid.—With the same notation we
$$\text{ume} = \pi\int_0^{x_1} y^2dx = 4\pi a\int_0^{x_1} x\,dx = \tfrac{1}{2}\pi \quad 4ax_1 = x_1 \quad \tfrac{1}{2}\pi y_1^2 \quad x_1;$$
olume of a paraboloid generated by the revolution of a part abola between the vertex and any point is equal to half the of the circumscribing cylinder.

If the coordinates of Q be x_2, y_2, then the volume of the PP'Q'Q
$$= \tfrac{1}{2}\pi\left\{y_2^2x_2 \quad y_1^2x_1\right\} - 2\pi a(x_2^2 - x_1^2) - \tfrac{1}{2}\pi(y_2^2 + y_1^2)h,$$
= MN; hence the volume of the frustum of a paraboloid to half the sum of the areas of its ends multiplied by its

F. *Ellipsoid*

Volume of an Ellipsoid. - The equation to the ellipsoid
$$\frac{x^2}{a^2} + \frac{y^2}{b^2} \quad 1,$$
ation to the elliptic section at the distance z from the
$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - 1 \quad \frac{z^2}{c^2}.$$
we draw an indefinite number of parallel planes per- ar to the axis of z, each slice will be an infinitely thin cal plate, and accordingly the whole volume of the ellipsoid $= \int A\,dz$, where A is the area of the elliptic section.

$= \pi ab\left(1 - \frac{z^2}{c^2}\right)$, § 51,

$$\text{volume} = \pi ab\int_{-c}^{c}\left(1 \quad \frac{z^2}{c^2}\right)dz = \tfrac{4}{3}\pi abc.$$

ere being an ellipsoid whose axes are all equal, we obtain

$$\text{volume of sphere} \quad \tfrac{4}{3}\pi a^3 = \tfrac{4}{3}\pi r^3.$$

G. *Hyperboloid.*

Volume of an Hyperboloid. The hyperboloid is generated evolution of the hyperbolic segment ANP about AN (fig 0). If the coordinates of P be x_1, y_1, then

$$\text{olume of hyperboloid} = \pi\int_a^{x_1} y^2dx \quad \pi\frac{b^2}{a^2}\int_a^{x_1}(x^2 - a^2)dx$$
$$= \pi\frac{b^2}{a^2}\left\{\frac{x_1^3}{3} - a^2x_1 + \frac{2a^3}{3}\right\} = \frac{\pi b^2h^2}{3a^2}(3a + h),$$
where $h = \text{AN} = x_1 \quad a$.

, since x_1, y_1 is on the curve, we have

$b^2(a + h)^2 = \quad a^2b^2$, which gives $\frac{b^2}{a^2} = \frac{y_1^2}{2ah + h^2}$; whence

$$\text{volume of hyperboloid} = \frac{\pi hy_1^2}{3} \quad \frac{3a + h}{2a + h}.$$

Solids to which the "Prismoidal Formula" applies.

It was shown in § 72 that the volume of any polyhedron by two parallel planes and by plane rectilinear figures
$$\tfrac{1}{6}h(A_1 + 4A_2 + A_3),$$
A_1, A_3, and A_2 denote respectively the areas of the two ends he middle section.

ow proceed to show that the same formula determines the of all solids bounded by two parallel planes, provided the any section parallel to these planes can be expressed as a integral algebraic function of the third degree in x, where distance of the section from either plane.

Let $\phi(x) = A + Bx + Cx^2 + Dx^3 + \ldots + Kx^n$ denote t of the section in question

Now the solid between the sections $\phi(0)$ and $\phi(4)$ is equa solid between the sections $\phi(0)$ and $\phi(2)$ plus the solid betw sections $\phi(2)$ and $\phi(4)$. Hence if the prismoidal formula is in this case, we have
$$\tfrac{1}{6}h\left\{\phi(0) + 4\phi(2) + \phi(4)\right\}$$
$$= \tfrac{1}{12}h\left\{\phi(0) + 4\phi(1) + \phi(2)\right\} + \tfrac{1}{12}h\left\{\phi(2) + 4\phi(3) + \phi(4)\right\}$$
where h is the distance between the sections $\phi(0)$ and $\phi(4)$. Hence we have
$$\phi(0) - 4\phi(1) + 6\phi(2) - 4\phi(3) + \phi(4) = 0.$$

Now	$\phi(0)$	A						
	$4\phi(1)$	$-4A$	$4B$	$4C$	$4D$	$4E$	. . . .	$4K$
	$+6\phi(2)$	$6A$	$+12B$	$+24C$	$+48D$	$+96E$	. . . .	$+6\ 2^n$
	$-4\phi(3)$	$-4A$	$-12B$	$-36C$	$-108D$	$-324E$	. . . .	
	$+\phi(4)$	A	$+4B$	$+16C$	$+64D$	$+256E$	. . . .	$+4^nK$.

Therefore 0 0 0 0 0 $+24E + PF + \ldots + Tk$

Hence E F . . . . K 0, and therefore $\phi(x)$ must be tion of the third degree in order that the prismoidal formu apply.

§ 107. If we take $\phi(x) = A + Bx + Cx^2 + Dx^3$, there will be possible varieties as there are combinations of four things, o three, and four together, $= 4 + 6 + 4 + 1 = 15$ varieties. Corres to each of these there will be *at least one solid* the area of a of which at a distance x from one of the parallel pl $\phi(x) = A + Bx + Cx^2 + Dx^3$, and *at least one solid* of re generated by the curve whose equation is of the form
$$\pi y^2 = \phi(x) = A + Bx + Cx^2 + Dx^3.$$
As space prevents us discussing all the cases that may a content ourselves by giving three examples as illustrations.

(α) *Volume of an ellipsoid.* Here $\phi(x) = Bx + Cx^2$.

Let $2a$, $2b$, and $2c$ be the axes of which $2a$ is the greate $h = 2a$, $A_1 = 0$, $A_3 = 0$, and $A_2 = \pi bc$, therefore volume $= \frac{1}{6}h(A_1 + 4A_2 + A_3) = \frac{1}{3}a(4\pi bc) = \frac{4}{3}\pi abc$, which agrees with the result in § 104.

(β) *Volume of a sphere.* —Here $\pi a = \phi(x) = Bx + Cx^2$.

Let r be the radius of the sphere, then $h = 2r$, $A_1 = 0$, A_3 $A_2 = \pi r^2$, hence, as before (§ 91),
$$\text{volume of sphere} = \tfrac{1}{6}h(A_1 + 4A_2 + A_3) = \tfrac{2r}{6}(4\pi r^2) = \tfrac{4}{3}\pi r$$

(γ) *Volume of a right circular cone.* —Here $\pi a^2 = \phi(x) = C$.

Let r = radius of base and h the altitude, then $A_1 = 0$, and $A_2 = \pi(\frac{1}{2}r)^2$, hence
$$\text{volume of cone} = \tfrac{1}{6}h\left\{A_1 + 4A_2 + A_3\right\} = \tfrac{1}{6}h\left\{\pi r^2 + \pi r^2\right\} = \tfrac{1}{3}h$$

In a similar manner we can determine the volumes of a a prolate spheroid, an oblate spheroid, &c.

§ 108. In general, if in any solid we have
$$\phi(x) = A + Bx + Cx^2 + Dx^3,$$
where A, B, C, and D are known constants, then, if h be th of the solid,
$$A_1 = \phi(0) = A,$$
$$A_2 = \phi(\tfrac{1}{2}h) = A + B\tfrac{1}{2}h + C(\tfrac{1}{2}h)^2 + D(\tfrac{1}{2}h)^3,$$
$$A_3 = \phi(h) = A + Bh + Ch^2 + Dh^3,$$
and therefore
$$\text{volume of solid} = \tfrac{1}{6}h(A_1 + 4A_2 + A_3)$$
$$= Ah + \tfrac{1}{2}Bh^2 + \tfrac{1}{3}Ch^3 + \tfrac{1}{4}Dh^4.$$

I. *Solid of Revolution in General*

§ 109. *Volume of any Solid of Revolution.* Let P_1P_2 (fig. 34) be the generating curve and A_1 . . A_n the revolution. Divide the curve into portions in the points &c., and draw the chords and tangents of the small ar P_2P_3, &c., then it is evident that the solid generated by t is greater than the sum of the conical frusta traced out chords and less than the sum of the conical frusta traced ou tangents. Hence, by increasing the number of chords, an increasing the points of division of the curve, we can m difference between these sums as small as we please, and t by this method we can approximate as closely as we plea volume of the solid generated.

Assuming that the points P_1, P_2, P_3 are so near each ot the solid generated differs little from the frustum of a co using the same notation as in § 63, we have volume generat
$$P_1P_2P_3 = \tfrac{1}{3}\pi A_1A_2(s_1 + s_2) + \tfrac{1}{3}\pi A_1A_2(s_2 + s_3)$$
$$+ \tfrac{1}{6}\pi a(s_1^2 + 4s_2^2 + s_3^2);$$
similarly the volume generated by
$$P_3P_4P_5 = \tfrac{1}{6}\pi a(s_3^2 + 4s_4^2 + s_5^2),$$
whence the volume generated by the whole curve P_1P_2 . . .
$$= \tfrac{1}{6}\pi a\left\{s_1^2 + s_n^2 + 2s_2^2 + s_4^2 + \ldots + s_{n-2}^2 + 4s_3^2 + 4s_5^2 + \ldots + 4s_{n-1}^2\right\}$$

$\pi s_1^2 \frac{c_1}{4\pi}$, $\pi s^2 \frac{c^2}{4\pi}$, &c.

$c_1 : c_2 : 2c^2 : \ldots : c_3 : c_4 : \ldots : c_5 : c_6$

…n more convenient in practice, and it is sometimes more easy …ate equidistant circumferences than equidistant radii.

…e volume of the solid is equal to the product of the area of …olving curve and of the length of the path described by the …gravity of the curve.

…ntent ourselves with one example or two of the application …theorem, reference to the article INFINITESIMAL CALCULUS …mod-

Ex. 1. To find the surface and volume of a circular ring …the distance of the centre of the generating circle, in the …nch, from the axis of rotation and r the radius of the …on

perimeter of generating curve $= 2\pi r$,
area of generating circle $= \pi r^2$, and

…cribed by the centre of gravity either of the perimeter or …a, be

surface of ring $= 4\pi^2 cr$, and
volume of ring $= \pi r^2 \cdot 2\pi c$.

Ex. 2. To find the volume swept out by an ellipse whose …r and r', revolving about an axis in its own plane whose …from the centre of the ellipse is c.

…rea of generating curve $= \pi ab$,
…described by centre of gravity of area $= 2\pi c$, hence
volume generated $= \pi ab \cdot 2\pi c = 2\pi \cdot abc$.

Ex. 3. A circle of r inches radius, with an inscribed regular …revolves about an axis x inches distant from its centre, and …one side of the hexagon, to find the difference in area of …ated surfaces and volumes.

Here perimeter of circle $= 2\pi r$,
and perimeter of hexagon $= 12 r \sin 30° = 6r$ (§ 17).

and area of hexagon $= 3r^2 \sin 60°$ (§ 18, β)
$= \frac{3}{2}\sqrt{3}r^2$;

…ference of surfaces generated
$= 4\pi \cdot x \cdot 6r - 12\pi r^2 = 24\pi xr - 12\pi r^2 = 12\pi r(2x - r)$,

…rence of volumes generated
$= 2\pi r^2 \cdot 3x - \frac{3}{2}\sqrt{3}r^2 \cdot 3x = 3\pi r^2(2x - \frac{3}{2}\sqrt{3}r)$.

PART III. GAUGING.

By *Gauging* is meant the art of measuring the volume of a …any portion of it. The subject is one of great interest and …importance, but space will only permit us to discuss it very …If the cask whose capacity we wish to determine be a solid …ation, then its volume can at once be computed, either …or approximately, by the methods already described.

It is usual to divide casks into the following four classes, a… to the nature of the revolving curve:

(α) the middle frustum of a spheroid;
(β) the middle frustum of a parabolic spindle;
(γ) two equal frusta of a paraboloid, united at their base…
(δ) two equal frusta of a cone, united at their bases.

Casks of the second, third, and fourth variety are rarely m… in practice, and we shall accordingly confine our attention… first kind, which is considered the true or model form of ca…

Let ABCD (fig. 56) be a section of the cask, and assume… the middle frustum of a prolate spheroid, then

its volume $= \frac{1}{12}\pi(2b^2 + bb_1 + \frac{3}{4}b_1^2)k$,

where $b = OY$, $b_1 = AX$, and $k = XX'$ (§ 99).

YY' is called the bung diameter, and AB or CD th… diameter.

An imperial gallon contains 277·274 cubic inches, and t… the number of gallons in the above cask

$$\frac{\pi}{3} \cdot \frac{2b^2 + bb_1}{277 \cdot 274} k = \frac{\pi}{831 \cdot 822}(2b^2 + bb_1)k$$
$$\left(\frac{2b^2 + d^2}{1059}\right)k, \text{ where } d = 2b,\ d_1 = 2b_1;$$

whence we have the rule … to the square of the head … add twice the square of the bung diameter, multiply the sum… length and divide the result by 1059·1, and the answer is… tent in imperial gallons.

Casks are ordinarily met with are not true spheroidal fru… it is better to consider them as such, calculate their capacity on this assumption, and then make allowance for the departure from the spheroidal form. The determination of the proper allowance to be made in each case is a matter depending on the skill and experience of the gauger, and proficiency in the art can only be attained by considerable practice.

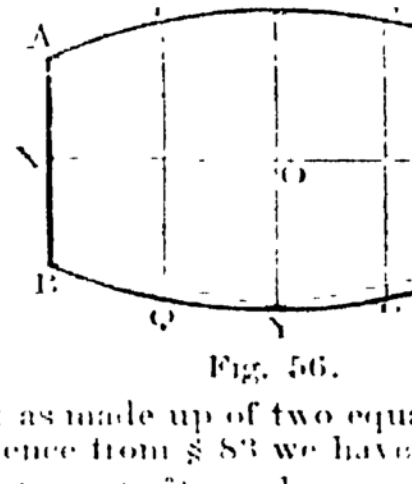

Fig. 56.

§ 112. If the cask be very little curved, we obtain an approximation to its capacity by considering it as made up of two equa… of a cone, united at their bases. Hence from § 83 we have

volume of cask $= \frac{1}{3}\pi h(r_1^2 + r_1r_3 + r_3^2)$ nearly.

Here we neglect the small volumes generated by APY… BQY', and YRC', and therefore the volume is too small.

If we put $r_1r_3 = r_1^2$, we obtain

volume $= \frac{1}{3}\pi h(2r_1^2 + r^2)$,

which is a little too large, and therefore the true volume lies… these two limits, and a very close approximation to it is s… given by the formula

§ 113. *Ullage of a Cask.* The quantity of liquor contai… cask, partially filled and the capacity of the portion which i… are termed respectively the wet and dry ullage.

(α) *Ullage of a standing cask.*—By means of the method… in § 105, the following rule is deduced:—

Add the square of the diameter at the surface, the square… diameter at the nearest end, and the square of double the… half way between, multiply the sum by the length betw… surface and the nearest end, and by ·00172.

The product will be the wet or dry ullage according as th… portion of the cask is filled or empty.

(β) *Ullage of a lying cask.* The ullage in this case i… approximately on the assumption that it is proportional to… ment of the bung circle cut off by the surface of the liqu… rule adopted in practice is:

ullage = ⅔ content × segmental area. (

…TON (Ital. *Mentone*), a cantonal capital in the …ment of Alpes Maritimes, France, situated 15 miles …st of Nice, on the border of the Mediterranean. …n, which has a population of about 8000, rises … amphitheatre on a promontory by which its semi… bay (5 miles wide at its entrance, and bounded on … by Cape Martin and on the E. by the cliffs of La …) is divided. It is composed of two very distinct …, below, along the sea-shore, is the town of hotels … and of foreigners, which alone is accessible to v… vehicles; above is that of the native Mentonese… steep, narrow, and dark streets, spread over and c… to the mountain, around the strong castle which w… its protection against the attacks of pirates. Faci… south-east, and sheltered on the north and west b… mountains, the Bay of Menton enjoys a delicious c… and is on this account much frequented by inva… quiring a mild and equable temperature. The me… the year is 61° Fahr., exceeding that of Rome…

and equalling that of Naples. Frost occurs on verage only once in ten years; in one particular he thermometer did not fall below 16° Fahr. In r the heat is never very great, the temperature exceeding 86° Fahr. Winter and summer are the greeable seasons; in autumn the rain storms are panied by sudden changes of temperature, and in the sea breezes are apt to be violent. Besides the s of its climate, Menton offers those of an almost al vegetation. Lemon trees, olive trees, and pines, above each other in successive stages, adorn the ing slopes. The district produces forty millions of s yearly, and this is the principal source of its natural . The olive-trees are remarkable for the great size ave attained in the course of the centuries during they have continued to bear. Of their wood a ude of fancy objects are made for sale to strangers.

origin of Menton is unknown. During the Middle Ages it ccessively occupied by the Saracens, the Genoese, and the of Anjou. In the middle of the 14th century it was pur as a single domain by the Grimaldis, lords of Monaco the times of the republic and the first empire it belonged nce, but in 1815 it again became the property of the of Monaco, who subjected it to such exactions that in 1848 abitants, weary of finding their reasonable demands put off mpty promises, proclaimed their town free and independent, the protection of Sardinia. Menton, with the neighbouring ne of Roquebrune, was united to France in 1860, at the same Nice and Savoy.

ENTZ. See MAINZ.

ENZEL, WOLFGANG (1798–1873), poet, critic, and ian, was born June 21, 1798, at Waldenburg in , studied at Breslau, Jena, and Bonn, and after for some time in Aarau and Heidelberg finally d in Stuttgart, where, from 1830 to 1838, he had a in the Wurtemberg "landtag." His first work, a and original volume of poems, entitled *Streckverse* elberg, 1823), was followed in 1824–25 by a popular *chte der Deutschen* in three volumes, and in 1829 830 by *Rübezahl* and *Narcissus*, the ballads upon his reputation as a poet chiefly rests. In 1851 he hed the romance of *Furore*, a lively picture of the d of the Thirty Years' War; his other very numerous gs include *Geschichte Europa's*, 1789–1815 (1853), istories of the German war of 1866 and of the o-German war of 1870–71. From 1825 to 1848 el edited a "Literaturblatt" in connexion with the *nblatt*; in the latter year he transferred his allegiance the Liberal to the Conservative party, and in 1852 "Literaturblatt" was again revived in that interest. 66 his political sympathies again changed, and all his es were employed to oppose the "particularism" of Prussian "junkers" and the antiunionism of South any. He died on April 23, 1873. His large private y of 18,000 volumes was afterwards acquired for the rsity of Strasburg.

EPHISTOPHELES, the name of one of the personi ns of the principle of evil. In old popular book puppet-plays the word appears in various forms, ephistopheles, Mephistophiles, Mephistophilis, and ostophilis. In the *Tragical History of Doctor us*, Marlowe writes "Mephistophilis"; in the *Merry of Windsor* we find "Mephistophilus." The etymo of the word is uncertain. According to one theory, y be taken to represent *μηφιστοφίλης*; in which case eaning would be "one who loves not light." Another y is that the word is a combination of the Latin hitis" and the Greek *φίλος*, signifying "one who noxious exhalations." Probably it is of Hebrew —from מפר, a destroyer, and טפל, taken to mean a This view is supported by the fact that almost all the names of devils in the magic-books of the 16th spring from the Hebrew. In the old Faust leger character of Mephistopheles is simply that of a pe and wicked being who fulfils Faust's commands in o obtain possession of his soul. Marlowe attributes a certain dignity and sadness, and there can be little that the Mephistophilis of the *Tragical History* sug some important traits of Milton's Satan. The na been made famous chiefly by Goethe, whose concep the character varied at different periods of his care the fragment of *Faust* published in 1790, but many years before, Mephistopheles has a clearly individuality; he is cynical and materialistic, but man's delight in activity and adventure, and his feats alone remind us that he is preternatural. In and extending this fragment, which forms the chief of the first part of *Faust*, Goethe treated Mephist as the representative of the evil tendencies of especially of the tendency to denial for its own sake than as a living person. This character Mephist maintains in the second part, where, indeed, the nam stands for a pure abstraction.

See Julius Mosen, *Faust*; Duntzer, *Charakteranlage zu Goethes Faust*; Vrchlicky, *Goethe's Faust*.

MEQUINEZ (the Spanish form of the Arabic *Me* a town of Morocco, the ordinary residence of the e is situated in a fine hilly country about 70 miles fr west coast and 35 west south-west of Fez on the Sallee, in 34° N. lat. and 5° 35′ W. long. The tow with its four-cornered towers, is kept in good co and a lower wall of wider circuit protects the lu gardens with which the outskirts are embellished. general regularity of its streets, and in the fairly sub character of its houses, Mequinez ranks higher th other town in Morocco; but it possesses few build any note, except the palace, and the mosque of Mulei which serves as the royal burying-place. At one t palace (founded in 1631) was an imposing structu the finest part has been allowed to go to ruin. I Windhus described it as "about 4 miles in circum the whole building exceeding massy, and the walls part very thick; the outward one about a mile long feet thick." The best part consisted of oblongs c large open courts or gardens. Mortar or concrete principal material used for the walls, but the pilla in many cases marble blocks of great beauty and c (*A Journey to Mequinez*, London, 1725). Most inhabitants of Mequinez are connected more or less with the court. Their number has been very va estimated by different travellers. Graberg de Hem 56,000 in 1831, Rohlfs in 1861 from 40,000 to and Conring in 1880 about 30,000. The tow formerly called Takarart. Edrisi refers the presen to a Berber chief Meknas.

MERAN a favourite health resort, and the capi district in South Tyrol, Austria, is picturesquely at the foot of the vine-clad Kuchelberg, on the rig of the Passer, about half a mile above its junction w Adige, and 45 miles to the south of Innsbruck proper consists mainly of one long narrow street the Laubengasse, flanked by covered arcades. In sense, the name is often used to include the a villages of Untermais, Obermais, and Gratsch. Th noteworthy buildings are the Gothic church of St N with its lofty tower, dating from the 14th an centuries; the Spitalkirche, built in the 15th centu restored in 1880; and the quaint old Furstenh residence of the counts of Tyrol. The town co gymnasium, a nunnery and school for girls, an ins for sick priests, and several other charitable establish

owes its high reputation as a resort for consumptive vous invalids to the purity of its air and its com- immunity from wind and rain in winter. It stands 11′ N. lat., at a height of 1050 feet above the sea, s a mean annual temperature of about 51° Fahr. enjoys three seasons, being also visited in spring whey cure and in autumn for the grape cure. The ment for the comfort of the visitors are very com and the environs afford opportunity for numerous t walks and excursions. The favourite promenade of abitants is on a massive dyke, built to protect the gainst the encroachments of the Passer. Nearly old castles and chateaux are visible from the bridge e Passer, the most interesting being Schloss Tyrol, ent edifice which has given its name to the entire . Meran is now frequented by about 6500 patients 00 to 9000 passing travellers annually. In 1880 its ion, including Obermais and Untermais, amounted 4 souls.

is probably the representative of the Roman Urbs Majensis, ls known as Maiania. It became a town in 1290, and 1490 was the capital of the counts and dukes of Tyrol. n suffered somewhat during the Peasants' War in the 16th and subsequently from destructive floods. As a health- has been known for about forty years. The whole region t best is singularly rich in historic interest.

RCATOR, GERARDUS (Latinized form of Gerhard r) (1512–1594), mathematician and geographer, was t Rupelmonde in Flanders, May 5, 1512. Hav- mpleted his studies at Louvain, he devoted him- geography, and, after being for some time attached household of Charles V., he was appointed cosmo- r to the duke of Julliers and Cleves in 1559, taking residence at Duisburg, where he died December 2, One of his earliest cartographical works was a rial globe (1541), followed in 1551 by a celestial In 1552 he published a treatise *De usu annuli mici* (Louvain), and at Cologne in 1569 his *Chrono- hoc est temporum demonstratio . . . ab initio mundi ad Annum Domini* 1568, *ex eclipsibus et observa- s astronomicis, sacris quoque Bibliis*, &c. In the same is published the first map on Mercator's well-known ion, with the parallel and meridians at right angles, in navigation. At Cologne, in 1578, appeared his *geographica ad mentem Ptolemæi restituta et emend-* The work by which he is chiefly known is his atlas, ed in 1594 at Duisburg, in folio, under the title of *sive Cosmographicæ meditationes de fabrica mundi*. tains, besides the maps, cosmographical and other ations, some of the theological views in which were ned as heretical; it was completed by Hondius in Several of the maps had been previously published ely, the atlas being delayed to allow Ortelius to te his. Mercator also published in 1592 a *Har Evangeliorum*.

RCURIAL AIR PUMP. This name is given to stinct instruments, one of which is founded on , the other on hydrodynamical principles.

The Statical Pump. The famous spiritualist Sweden- us the first to conceive an air-pump in which a mass reury, by being made to rise and fall alternately a vertical vessel, should do the work which in the y instrument is assigned to the piston. He pub- a description of his pump in 1722; but it is nable whether his design was ever realized. Of us subsequent inventions the only one which, in s survived is the admirably simple and yet efficient ent first described in 1858, but constructed some time before, by H. Geisler of Bonn, which at once justly, met with universal acceptance.

The general scheme of Geisler's pump is shown in A and B are pear shaped glass vessels connected by narrow india-rubber tube, which must be sufficiently strong in the body (or strengthened by a linen coating) to stand an outward pressure of 1 to 1½ atmospheres. A terminates below in a narrow vertical tube *c*, which is a few inches longer than the height of the barometer, and to the lower end of this tube the india-rubber tube is attached which connects A with B. To the upper end of A is soldered a glass two-way stop-cock, by turning which the vessel A can either be made to communicate through *s* and a hole in the hollow cock with the vessel to be exhausted (I., fig. 2), or through *g* with the atmosphere (II., fig. 2), or can be shut off from both when the cock holds an intermediate position. The apparatus, after having been carefully cleaned and dried, is charged with pure and dry mercury, which must next be worked backwards and forwards between A and B to remove all the air bells. The air is then driven out of lifting B to a sufficient level, turning the cock into po II., and letting the mercury flow into A until it g the other side of the stop-cock, which is then pla the intermediate position. Supposing the vessel to be exhausted to have already been securely connected with *b*, we now lower the reservoir B so as to reduce the pressure in A sufficiently below the tension in the gas to be sucked in, and, by turning the cock into position I., cause the gas to expand into and almost fill A. The cock is now shut against both *a* and *b*, the reservoir lifted, the gas contents of A discharged through *a*, and so on, until, when after an exhaustion mercury is let into A, the metal strikes against the top without interposition gas bell. In a well-made apparatus the pressure exhausted vessel is now reduced to $\frac{1}{100}$ or $\frac{1}{200}$ of a metre, or even less. An absolute vacuum cannot b duced on account of the unavoidable air-film betwee mercury and the walls of the apparatus.

FIG. 1. — Gei Mercurial Air-

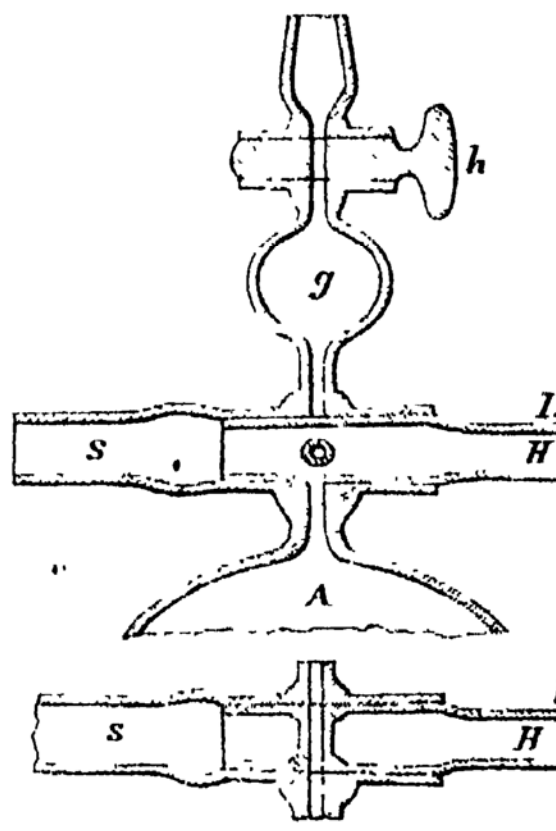

FIG. 2.— Arrangements of Stop in Air-Pump.

The great advantage of the mercurial over the ordinary ai is that it evacuates far more completely than the latter, affords direct and unmistakable evidence of the exhaustive its work, and—last not least—that it enables one to transfer sucked out to another vessel without loss or contamination, it can be measured and analysed. On account of this latter more especially, the instrument is highly valued as an auxil gasometric researches. Without it the researches of whic our present knowledge of the gases of the blood could not ha carried out. The actual instrument, as constructed for kinds of work, has of course various complexities of detail in the above description. For these the reader must refer t books of practical physiology.

takes a height of about 30 inches of mercury to balance sure of the atmosphere, a Geisler pump necessarily is a t long-legged and unwieldy instrument. It can be con- y shortened, the two vessels A and B brought more closely , and the somewhat objectionable india-rubber tube be dis- with, if we connect the air-space in B with an ordinary an- nd by means of it do the greater part of the sucking and le of the lifting work An instrument thus modified was ted by Poggendorff (see his *Annalen*, vol cxxv. p 151, nd another, on somewhat different principles, by Prof. (see the "*Challenger*" *Reports*).

a Geisler's stop-cock requires to be lubricated to be abso- as-tight, and this occasionally proves a nuisance Hence a of attempts have been made to do without stop-cocks alto- In Topler's pump[1] this is attained by using both for the d the outlet vertical capillary glass tubes, soldered, the o somewhere near the bottom, the latter to the top of the These tubes, being more than 30 inches high, obviously fficient mercury traps; but the already considerable height mp is thus multiplied by two. This consideration has led er Mitscherlich (*Pogg. Ann.*, cl 420, 1873), and quite . Neesen (*Z. f. Instrumentenkunde*, 1882, p 285) to intro ss valves in lieu of stop cocks. As glass floats on mercury, ves do not necessarily detract from the exhaustive power mp.

The Dynamic Pump.—This was invented in 1865 by renge1. The instrument, in its original (simplest) ig. 3), consists of a vertical y glass tube *a* of about . bore, provided with a branch *b* near its upper hich latter, by an india- joint governable by a screw- communicates with a funnel. wer end is bent into the of a hook, and dips into a atic trough. The vessel to austed is attached to *b*, and, r to extract its gas contents, rly regulated stream of mer- allowed to fall through the tube. Every drop of mer s it enters from the funnel, closes the narrow tube like n, and in going past the here the side tube enters a portion of air and carries to the trough, where it can ected. If the vertical tube, ing from the point where nch comes in, is a few inches than the height of the ter, and the glass and mer e perfectly clean, the apparatus slowly but surely es an almost absolute vacuum.

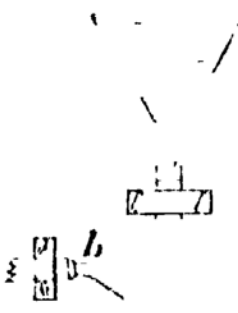

Fig. 3. - Sprengel Air-Pump

reat advantages of Sprengel's pump lie in the simplicity of truction and in the readiness with which it adapts itself to cting of the gas. It did excellent service in the hands of for the extraction of gases occluded in metals, and since s become very popular in gas-laboratories, especially in Many improvements upon the original construction have posed One of these which deserves mention is to pass the , before it enters the "falling" tube, through a bulb in good vacuum is maintained, by means of an ordinary air a second "Sprengel." (W. D.)

RCURY was the Roman god who presided over trade, and all commercial dealings. His nature is ly more intelligible and simple than that of any Roman deity. His very name, which is connected *ner*, *mercator*, &c., shows that he is the god of ndise and the patron of merchants. In the native states no merchants and no trade existed till the re of the Greek colonies on the coast introduced customs into the cities of the land. All the usages and terminology of trade, and all the religious cere connected with it, were borrowed by the Romans fr Greeks. It was no doubt under the rule of the Ta when the prosperity of the state and its intercours the outer world were so much increased, that me began to ply their trade in Rome. Doubtle merchants practised their religious ceremonies fr first, but their god Mercurius was not officially rec by the state till the year 495 B.C. Rome frequently s from scarcity of corn during the unsettled time followed the expulsion of the Tarquins. Various r innovations were made to propitiate the gods, in Greek worship of Demeter, Dionysus, and Pers was established in the city (see LIBER), and in Greek god HERMES (*q.v.*) was introduced into Rom the Italian name of Mercurius (Livy, ii. 21, 27). thinks that at the same time the trade in corn wa lated by law, and a regular college of merchan instituted. This *collegium* was under the protection god; their annual festival was on the Ides of M which day the temple of the god had been dedic the southern end of the *circus maximus*, near the Av and the members were called *mercuriales* as w *mercatores*. The Ides of May was chosen as the Mercury, obviously because Maia was the mot Hermes, *i.e.*, of Mercury (see MAIA); and she w shipped along with her son by the *mercuriales* day. According to Preller, this religious foundat a political object; it established on a legitimate a basis the trade between Rome and the Greek col the coast, whereas formerly this trade had been exp the capricious interference of the Government offic the year. Like all borrowed religions in Rome, have retained the rites and the terminology of its original (Festus, p. 257). Mercury became the g only of the *mercatores* and of the corn trade, but of and selling in general, and it appears that, at leas streets where shops were common, little chapels and of the god were erected. There was a spring dedic Mercury between his temple and the *Porta Capena* shopman drew water from this spring on the Ides and sprinkled it with a laurel twig over his head a his goods, at the same time entreating Mercury to from his head and his goods the guilt of all his (Ovid, *Fasti*, v. 673 *sq.*). The art of the Roman tra was evidently like that of an Oriental tradesman in times, and the word *mercuriales* was popularly equivalent to "cheat. In the Latin poets Mercury gifted with some of the manifold characters of the Hermes, but this finer conception seems to have real existence in Roman religion.

Roman statuettes of bronze, in which Mercury is represen the Greek Hermes standing holding the caduceus in the and a purse in the other, are exceedingly common. The must have been introduced as a symbol of Mercury at a v time, for it is found on Italian coins as early as the 4th before Christ, and we learn that several were kept as sacre in the *adytum* of the sanctuary at Lavinium (Dion. Hal But its foreign origin is shown by the fact that, although sign of peace, it was never borne by the *fetiales*, the old heralds. The very name is derived from the Greek Preller's view (*Rom. Myth.*) that *mercuriales* and *mercu* the same guild is a tempting one, but its truth is very Mommsen thinks that *mercuriales* were a purely local gu the *pagani* of the Circus valley

MERCURY, in chemistry, is a metal (symbol Hg is easily distinguished from all other by its being at even the lowest temperatures naturally occu moderate climates. To this exceptional property the synonyms of *quicksilver* in English (with the G *quecksilber* is the only recognized name) and of *gyrum* (from ὕδωρ, water, and ἄργυρος, silver) in Greec

[1] *Dingler's Polytechn. Journal*, 1862; an improved form by Hagen is described in *Wiedemann's Annalen*, xii. 425, 1881.

etal does not appear to have been known to the Jews, nor is it mentioned by the earlier Greek Theophrastus (about 300 B.C.) mention it a ve of cinnabar. With the alchemist it was a ce of great consequence. Being ignorant of its ibility of freezing into a compact solid, they did not ze it as a true metal, and yet, on the authority of they held that mercury (meaning the predominating in this metal) enters into the composition of all and is the very cause of their metallicity. When, he beginning of the 16th century, chemistry and ic medicine came to merge into one, this same ous element of "mercury" played a great part in ories of pathology and the metal, in the free as in combined states, came to be looked upon as a al medicinal agent, which position, on purely em ground, it continues to hold to the present day

ury occurs in nature chiefly in the form of a red e, HgS, called cinnabar, which, as a rule, is accom by more or less of the regulus metal, the latter probably derived from the former by some secondary n. The most important mercury mines in Europe se of Almaden in Spain and of Idria in Illyria, until lately furnished the bulk of the mercury of ce, but they are now almost eclipsed by the rich s of New Almaden in California. Considerable ies of mercury are said to be produced in China and n, minor deposits are being worked in the Bavarian ate, in Hungary, Transylvania, Bohemia, and Peru. aden the ore forms mighty veins traversing micaceous of the older transition period, in Illyria it is dis ted in beds of bituminous schists or compact lime l more recent date.

nically speaking, the extraction of mercury from its a simple matter. Metallic mercury is easily vola and separated from the gangue, at temperatures far redness, and cinnabar at a red heat is readily reduced metallic state by the action of iron or lime or heric oxygen, the sulphur being eliminated, in the se as sulphide of iron, in the second as sulphide phate of calcium, in the third as sulphurous acid To the chemical mind a close iron retort would itself as the proper kind of apparatus for carrying se operations, but this idea is acted upon only in mall establishments, for instance, in that of Zwei- in the Palatinate, where lime is used as a decom- agent. In a few large works the decompo cinnabar is effected by the direct exposure of the the oxidizing flame of a furnace, and the mercury , which of course gets diffused through an immense f combustion gases, is sought to be recovered in less imperfect condensers.

Almaden chiefly used for distillation are of two kinds, which, by the way, are also employed in prismatic , the lower chamber, the upper chamber, the latter serving for the re-

he upper accommodates the ore, which is introduced through ing in the dome-shaped roof. To avoid an excessive dilu the mercury vapour with combustion gases, part of these are laterally into a chimney and the rest allowed to strike up the heap of ore. The large mass of metalliferous vapour d passes out through a system of pipes inserted laterally into e and so arranged that they follow first a descending and ascending plane, to lead ultimately into a condensation which communicates in its turn with a chimney. The e formed each of a large number of cone-to-cone pear-shaped ware adapters, called *aludels*, which are telescoped into ther as in the case of the iodine-sublimation apparatus, the being luted with clay. The lowest row of aludels, which e line of intersection of the two inclined planes are pierced oles below, so that what arrives as liquid mercury there t into a gutter leading to a reservoir. What of mercury remains uncondensed in the aludels passes into the chamber, ention being to have it condensed there, in reality a large ion of the mercury passes out through the chimney (and through the numerous leaks in the aludels) into the atm to poison the surrounding vegetation and the workmen. furnaces to the Almaden ones are used in Idria and Almaden, only the condensation apparatus are a little perfect. But in all three places the loss of metal is very c able, at New Almaden it is said to amount to close upon 40 p

The mercury obtained is purified mechanically by stra through dense linen bags, and then sent out into commerce in bags, or in wrought-iron bottles provided with screw plug holding about 75 lb avoirdupois.

According to Balling's *Metallurgische Chemie* 1882), the production of mercury in the years nam as follows:

Austria, exclusive of Hungary (1880)	369
Hungary (1879)	180
Italy (1877)	
Spain (1873)	929
United States (1875)	2054

Assuming the amount to be the same from year t this gives a total of 3587 tons.

The price of the metal is subject to immense fluctua it generally ranges from 2s. to 7s. 6d. a pound avoir

Commercial mercury, as a rule, is very pure chem so that it needs only to be forced through chamois to become fit for all ordinary applications; but the having the power of dissolving most ordinary other is very liable to get contaminated with these in the tory or workshop, and requires then to be purified this purpose a great many chemical methods hav proposed, which, however, all come to this, th base admixtures are sought to be removed by tre with nitric acid, oil of vitriol, or other agents wh preferably on the impurities. The best of these m is that of Bruhl, who shakes the metal with a solu 5 grammes of bichromate of potash and a few cubic metres of sulphuric acid in one litre of water, until chromate of mercury, first produced, has disappear its place been taken by green chromic sulphates supernatant liquor and chromic scum are washed a a powerful jet of water, and the clean metal is dri filtered through a perforated paper filter. The only exhaustive method is redistillation out of a glass app Unfortunately the operation is difficult of execut mercury "bumps" badly on boiling; but this avoided by distilling the metal in a *perfect* vacuum ingenious apparatus for this purpose, in which the metal itself is made to keep up the vacuum, wa structed lately by Leonhard Weber. A U tube, th of which are longer than the height of the baro filled with pure mercury, and inverted, the on being made to dip into a vessel with pure, th into another containing the impure, mercury. This limb is inflated above so that the meniscus is ab middle of the bulb. This bulb is heated, and the quence is that the metal there distils over into t limb to add to the supply of pure metal, the rising up in the second by itself to maintain a c level. Dewar has modified the apparatus so tha is no need of a supply of pure metal to star Absolutely pure mercury does not at all adhere surface which does not consist of a metal soluble in m Hence the least quantity of it, when placed on a paper, forms a neatly rounded-off globule, which ret form on being rolled about, and, when subdivided, up into a number of equally perfect globules. The p in it of the minutest trace of lead or tin causes it to tails." A very impure metal may adhere even t and in a glass vessel, instead of the normal convex an irregular flat meniscus.

Properties. The pure metal is silver-white, and its strong lustre even on long exposure to ordin At −38·8 C., *i.e.*, −37·9 F. (Balfour Stewart), it

considerable contraction, into a compact mass of r octahedra, which can be cut with a knife and be ged under the hammer. The specific gravity of the metal is 14·39; that of the liquid metal at 0° C. is 5 (water of 4° C. = 1). Under 760 mm. pressure s at 357°·3 C. (675°·1 Fahr.) (Regnault). At very emperatures it seems to be absolutely devoid of ity (Faraday); but from - 13° C. upwards (Regnault) ibits an appreciable vapour tension.

following table gives the tensions "p," in millimetres rcury of 0° C., for a series of centigrade temperatures cording to Regnault :—

0°	10°	20°	50°	100°	150°	200°
·02	·03	·04	·11	·75	4·27	19·90

- 250°	300°	350°	400°	450°	500°
75·75	242·1	663·2	1588	3384	6520

ling to the same authority, its average coefficient ansion k per degree C. is as follows :—

0 100° C.	0 200° C.	0 300° C.
k = ·0001815	·0001841	·0001866
1/5510	1/5432	1/5359

pecific heat in the liquid state is ·03332, that of ozen metal (between - 78° and - 40° C.) is ·0319 ault). Its electric conductivity is $_{a}^{1}/_{7}$ of that of pure (Matthiesen). Its conductive power for heat is r than that of water, and is proved (by Herwig) to rfectly constant from 40° to 160° C. Its vapour y (air of the same temperature and pressure = 1) is (Dumas), or 100·93 for hydrogen 1. Hence its ular weight ($H_2 = 2$) is 201·86. The atomic weight, emical methods, was found = 200·0 (Erdmann and and); hence mercury vapour molecules consist of atoms. Mercury does not appreciably absorb any ally inert gas.

cury is in constant requisition in the laboratory. It for the collecting and measuring of gases, in the uction of thermometers, barometers, and manometers, determination of the capacity of vessels, and many urposes. In medicine it serves for the preparation curial ointment and of "hydrargyrum cum creta" nief component of "blue pills"); both are obtained gently triturating the metal with certain proportions se and chalk respectively until it is "deadened," *i.e.*, ided into invisibly small globules (see below).

ys.—Mercury readily unites directly with all metals t iron and platinum) into what are called amalgams. ne cases the union takes place with considerable ion of heat and large modification of the mean pro- of the components. Thus, for instance, sodium rubbed up with mercury unites with it with deflagra d formation of an alloy which, if it contains more per cent. of sodium, is hard and brittle, although is as soft as wax and mercury a liquid. Liquid ms of gold and silver are employed for gilding and ng objects of copper, bronze, or other base metal. malgam is spread out on the surface of the object ans of a brush, and the mercury then driven off application of heat, when a polishable, firmly ng film of the noble metal remains. Copper m containing from 25 to 33 per cent. of the solid when worked in a mortar at 100° C., becomes highly but on standing in the cold for ten or twelve hours es hard and crystalline. Hence it is used for the g of teeth. A certain amalgam of cadmium is ly employed.

s.—There are two oxides of mercury, namely, an oxide, called mercurous, and another, HgO, called mercuric oxide er can be produced directly by keeping the metal for a long air at a temperature somewhat below its boiling point, e oxide is gradually formed as a red powdery solid. This s long been known as "red precipitate," or as *mercurius praecipitatus per se*. Priestley made the important disco the "precipitate" when heated to dull redness is reduced t with evolution of what has since been known as oxygen g was reserved for Lavoisier to correctly interpret this expe and thus to establish our present views on the constit atmospheric air. The oxide is easily prepared by heat nitrate of the metal as long as nitrous fumes are seen (when it remains as a scaly mass, black when hot, red after or else by precipitating the solution of a mercuric salt wit of caustic potash or soda, when it comes down as an am yellow precipitate, which is free of combined water. Me oxide, a black solid, can be obtained only indirectly, by the position of mercurous salts with fixed caustic alkalies. Bot are insoluble in water, but dissolve in certain, and combi all, aqueous acids with formation of mercury salts and elim of water. Thus, for instance,

$$Hg_2O + 2HNO_3 = H_2O + Hg_2(NO_3)_2.$$
Mercurous nitrate

$$HgO + 2HNO_3 = H_2O + Hg(NO_3)_2.$$
Mercuric nitrate

The Nitrates. When metallic mercury is set aside with weight of nitric acid of 1·2 specific gravity, at ordinary t tures, the normal mercurous salt $Hg_2(NO_3)_2$ is gradually pr and after a day or two is found to have separated out in co crystals. These are soluble (somewhat sparingly) in water lated with nitric acid, but are decomposed by the action water, with formation of difficultly soluble basic salts this salt (or the metal itself) is treated with excess of nitric is oxidized into mercuric nitrate $Hg(NO_3)_2$, a white crystalli readily soluble in water without decomposition.

The Sulphates. Cold aqueous sulphuric acid does not a mercury, but the hot concentrated acid converts it fi mercurous and then into mercuric sulphate, with evolu sulphurous acid

$$Hg_2 + 2H_2SO_4 = 2H_2O + SO_2 + Hg_2SO_4,$$
$$Hg_2SO_4 + 2H_2SO_4 = 2H_2O + SO_2 + 2HgSO_4.$$

Both salts form white crystalline magmas. The mercur is difficultly soluble in water, and consequently produc precipitation of the nitrate with sulphuric acid. The mercu when treated with water, is decomposed with formation of a insoluble basic salt, which has long been known as *turpeth rab*. Its composition is $SO_3.3HgO$ when produced by e hot water. Mercuric sulphate is of importance chiefly as the basis for the manufacture of the two chlorides.

The Chlorides.—These are both extensively used medicinal The mercuric salt, $HgCl_2$, known in medicine as corrosi limate, is prepared by mixing the sulphate intimately with c salt, and subjecting the mixture to sublimation, a little o of manganese being added to oxidize the mercurous salt, w generally present as an impurity. The process is conduct glass flask buried in a hot sand-bath. When the decompos accomplished, the sand is removed from the upper half of t and the temperature raised so that the chloride $HgCl_2$ p sublimes up and condenses in the upper part as a "subl The salt, as thus produced, forms compact crystalline crusts, when heated, melt into a limpid liquid before volatilizing solvable in water, 100 parts of which at 10°, 20°, 100° dissolv 7·39, 54 parts of salt. Corrosive sublimate dissolves in 3 alcohol and in 4 parts of ether. This salt, on account solubility in water, is a deadly poison. Mercurous chloride, better known as "calomel" (from καλός, fair, and μέλας, because it becomes dead-black when treated with ammoni curic chloride yielding a white product), is prepared by corrosive sublimate with the proper proportion of metallic m ($HgCl_2 \cdot Hg$) or mercuric sulphate with salt and mercury proportions of $HgSO_4 + Hg + 2NaCl$, and subjecting the mix sublimation in glass flasks. The salt Hg_2Cl_2 is thus obta the form of white, opaque, crystalline crusts, which, when volatilize, without previously melting, into a mixture of and Hg vapour, which, on cooling, recombine into calome medicinal purposes the sublimate is reduced to an impa powder, washed with water to remove any corrosive sublima may be present, and dried. Being insoluble in water, it a less violently on the organism than mercuric chloride doe action, no doubt, is due to its very gradual conversion stomach into mercury and corrosive sublimate. Finely c calomel can be produced, without trouble, by the precipitati solution of mercurous nitrate with hydrochloric acid or c salt; but this preparation is liable to be contaminated mercurous nitrate, and, even when pure, has been found to more violently than ordinary calomel does. Hence its use tolerated by the pharmacopœias. According to Wöhler a mer chloride, more nearly equivalent to the sublimed article, is p ible by heating corrosive sublimate solution with sulphurous

$$2HgCl_2 + H_2SO_3 + H_2O = H_2SO_4 + 2HCl + Hg_2Cl_2.$$

vriter is unable to say whether Wohler's calomel has ever
s way anywhere into medicinal practi
Iodides The mercuric salt HgI_2 is produced in two ways,
st by mixing the two elementary components intimately
jecting the mixture to sublimation, and secondly by pre
g corrosive sublimate solution with its exact equivalent of
f potassium In the first case the salt is obtained in yellow
which, on the slightest touch with a solid body, assume
n permanently retain a rich scarlet colour The precipita-
cess at once yields the scarlet salt The salt is insoluble
, but soluble in alcohol and in iodide of potassium solution
ercurous salt Hg_2I_2 is obtained by *precipitating mercurous*
with iodide of potassium as a dirty-green powder insoluble
Both iodide are used medicinally
Sulphides Mercurous sulphide, Hg_2S does not seem to
The mercuric salt, HgS exists in two modifications, of
e is amorphous and has a black colour while the other is
ne and red The black one is obtained by precipitation of
of mercuric salt with excess of sulphuretted hydrogen,
ment synthetics The right proportions of mercury and
sulphur is rubbed together in a mortar until the whole
rted into a jet black uniform powder. This preparation
ot mercuric of the pharmacopœia is, however, apt to be
nated with uncombined sulphur and mercury Application
le heat causes explosive combination The red sulphide,
ur in nature as cinnabar, and can be produced artificially
black The artificial preparation, known as vermilion, is
alled as the most brilliant, stable, and innocuous of all
ed pigment Vermilion can be produced from the black
in two ways, viz., first by sublimation, and secondly by
t of it with fixed alkaline sulphide solution According
ner, 100 part of mercury are mixed intimately with 38 part
s of sulphur, and the sublimate is digested, with constant
, in a solution of 25 parts of potash in 150 parts of water at
e water lost by evaporation being constantly replaced, until
mation has become up to its maximum of fire and brilliancy,
ke of many hour Purely sublimed vermilion has a
tively dull colour, and must be manipulated with alkaline
at the essary fire. The action of the
ide consists probably in this that it dissolves successi-
ns of the amorphous preparation and redeposits them

Ammonia Derivatives or Ammonia (1) Recently precipitated
g is digested, cold, in carbonic acid free ammonia, and
are allowed to stand for
d off and the precipitate washed with alcohol and then
ter, and dried over sulphuric acid The product is a
ellow base ("Millon's base") of the composition

$$NH_2 \cdot HgO \cdot HO \quad N_2Hg_2O \cdot 2HO + 2H_2O$$

insoluble in alcohol and in ether and requires 13 000 parts
water for its solution readily unit all acids,
a rule, are insoluble in water, all
ydrates, when shaken with the base, are decomposed
Thus, for instance, even
ts of alkaline nitrates, chlorides, or sulphates are decom-
with formation of solutions of caustic alkali
body $NHg_2I_2 + 2HO$, *viz.*, of the composition of the iodide
ndance to the oxide in I, is produced as a brown precipitate
mmonia or an ammonia salt is added to a solution of mercuric
n iodide of potassium mixed with large excess of caustic
or soda ("Nessler's reagent"). In very dilute solutions of
a Nessler reagent produces only a brown or yellow color-
hich, however, is so intense that $\frac{1}{1000000}$th of ammonia in
cubic centimetres of liquid becomes clearly visible.
he chloride NH_2Hg_2Cl of the "ammonium" NH_4Hg is
d as an insoluble white precipitate when ammonia is added
ution sublimate This substance is known in
as infusible white precipitate, in contradistinction to (4).
he fusible white precipitate was at one time supposed to be
d with (3), and is obtained by boiling it with sal ammoniac
Its composition is $NH_2HgCl + NH_4Cl$ $N_2H_6Hg_2Cl_2$
yses Any ordinary solid mercury compound, when heated
blimation tube with carbonate of soda, yields a sublimate of
mercury, which, if necessary needs only to be scraped
with a wooden spill to unite into visible globules From any
-salt solution the metal is precipitated by digestion with a
bright copper-foil The precipitated mercury forms a coat-
the copper, which becomes silvery on being rubbed with
paper When the quicksilvered copper is heated in a sub-
tube, it reassumes its red colour with formation of a sub-
of mercury.
ions of mercurous salts with hydrochloric acid give a white
ate of calomel, which, after filtration, is easily identified by
ming jet-black on treatment with ammonia From mercuric
s hydrochloric acid precipitates nothing; but stannous
, in its twofold capacity as a chloride and a reducing agent,

yields a precipitate of calomel. On addition of an excess of
the precipitate becomes grey through conversion into finely
quicksilver Sulphuretted hydrogen, when added very g
to an acid mercuric solution, gives at first an almost white
tate, which, on addition of more and more reagent, assu
cessively a yellow, orange, and at last jet black colour. T
precipitate is HgS, which is identified by its great he
and by its being insoluble in boiling nitric and in boilin
chloric acid A mixture of the two (aqua regia) dissolv
chloride. (V

Therapeutics of Mercury.

The use of mercury as a therapeutic agent is c
paratively recent date. To the Greeks and Rom
value was unknown, and the Arabian physicians onl
it for skin affections. It was not till the middle
16th century that the special properties of mercur
fully appreciated, but since that time the metal ha
tinued to hold a high though fluctuating value
medicine. At first the metal in a finely divided s
in vapour was used, but very soon its various comp
were found to be endowed with powers even greate
those of the metal itself, and with the discovery
compounds the number of mercurial medicines has
increased.

The preparations now in use may be thus classifie
Of the preparations containing metallic mercury th
members are blue pill (pilula hydrargyri), grey p
(hydrargyrum cum creta), and blue ointment (ungu
hydrargyri). The first consists of mercury, liquoric
and confection of roses, the second of mercury and
the third of mercury, suet, and lard. The power
three preparations seems to depend on the fine s
subdivision of the mercury they contain; mercury
ordinary liquid state seems devoid of medicinal prop
It is thought by some that the fine subdivision
metal leads to the formation of a little oxide, and th
efficacy of the preparations in part depends on thi
Three oxides of mercury are employed in medicine
red, from which is made red precipitate ointment (u
tum hydrargyri oxydi rubri), the yellow, an allotropi
of the red, and the black oxide. The yellow and
oxides suspended in lime water form respectively
and black wash (lotio flava and lotio nigra). (
chlorides of mercury form a very important
calomel (hydrargyri subchloridum) is a white
powder; corrosive sublimate (hydrargyri perchlorid
a heavy crystalline substance. (4) Two iodides ar
medicinally; they are known from their colour
green and red iodides. (5) Nitrate of mercury ent
the composition of a powerful caustic known as t
nitrate of mercury. It is also the active principle of
ointment (unguentum hydrargyri nitratis). (6) In th
only ammoniated mercury and its ointment co
known as white precipitate ointment, are containe
the many compounds not included in the above cla
tion the oleate and albuminate are the most importa

Mercurial preparations are largely employed as externa
cations. Several of them are potent agents for the destru
the lower forms of animal life, and hence are employed to
parasites having their habitat in skin, hair, and clothin
white and red precipitate ointments are specially effectiv
destruction of pediculi, and blue ointment is occasionally
the same purpose. Corrosive sublimate is, however, th
energetic of the mercurial parasiticides, and recent obse
seem to show that it is superior to almost all other subst
a germ destroyer. It is sometimes used to get rid of ri
It should be remembered that corrosive sublimate is a
irritant to the skin, and also an active poison.

Acid nitrate of mercury is a caustic, and by it warts a
growths are sometimes removed; it is also one of the caust
sionally applied to prevent the spread of lupus.

In skin diseases mercurial preparations are largely used, e
in some forms of eczema. A few grains of the red oxi
ammoniated mercury in an ounce of zinc ointment are oft
of great service in this ailment; citrine ointment is also

ointment is not irritating, but rather tends to soothe It ore sometimes applied to irritable rashes; in pruritus ani pecial value. Mercurial preparations are not usually found t in scaly eruptions. In acne a weak solution of corrosive e is often most effective.

rations of mercury are often used to heal ulcers, especially syphilitic origin. Black wash is one of the commonest ons for this purpose. The red oxide ointment is at times d to stimulate indolent ulcers, and it is capable of removerant granulations (proud flesh), which sometimes retard ing of wounds

ry is largely used externally to promote the absorption of atory products, especially in the neighbourhood of joints. ointment is frequently employed for this purpose, more plaster containing mercury or a mercurial liniment. For the absorption of goitre (Derbyshire neck) the ointment d iodide is often relied on especially in India, where it is y to expose the patient's neck to the sun after rubbing it ointment. In enlargements of the liver and spleen the on of mercurial ointment sometimes seems to promote re- in size.

internally in continued doses, mercury produces a peculiar own as salivation First a metallic taste is experienced, followed by soreness of the gums, an undue flow of saliva, or of the breath Further administration of the drug may greatly the salivary flow, and also lead to swelling of the ulceration of the mouth, and even disease of the jaw-bone. ame time the blood becomes impoverished, and feverishness s of flesh occurs A single large dose—rarely too a single se may produce some of the above symptoms They may ow the inhalation of the metal or its compounds, or their n through the skin The long-continued inhalation of our of mercury acts likewise on the nervous system, causcular kind of trembling Mercurial tremor is sometimes looking-glass makers, often in those who work in quicksilvers.

ally mercury is chiefly given for two purposes (1) to nflammation and cause the absorption of the products it e to, and (2) to antagonize the syphilitic virus and remove s it causes Some years ago the belief in the power of to control inflammation was almost universal, and it was dministered in almost all inflammatory affections, but of has been much less used, both because it seems doubtful it has really the power it was once supposed to have and of the possibility of evil results from its continued use omitis and iritis it is still often employed, small doses of being given. Not unfrequently too it is administered in itis and hepatitis, but in pneumonia, pleurisy, and most nflammatory affections its use is now discarded by many ns As an antidote to the syphilitic poison it is still held esteem, though opinions vary much as to the extent of re- There can be little doubt that, given in an early stage of der, it minimizes the secondary symptoms; but it cannot l on to prevent their occurrence. It aids in removing the y symptoms, and tends to the avoidance of tertiary ations, which nevertheless sometimes occur even when has been freely given. The custom of giving mercury ause salivation is established has long been abandoned; now is so to give it as to prevent salivation occurring; for pose blue pill, calomel, and corrosive sublimate are given small doses, but if the gums become tender the dose is d or the administration stopped.

rial treatment is sometimes carried out by rubbing the blue t into the skin, sometimes by exposing the patient to the t calomel; syphilitic eruptions are often treated by such ion. More rarely mercury is introduced by injecting the ate or some other preparation under the skin or by means of ories. In children grey powder is generally used when mer eatment is required Children bear mercury well.

pill, calomel, and grey powder are often used as purgative, power of promoting the secretion of bile is attributed to Experimentally it has not been proved that they stimuliver functions, but there is good reason for believing that omote the expulsion of bile from the body. Grey powder is ly valued as a mild and efficient aperient for children and given in the early stage of diarrhoea to expel the irritating s of the bowel.

se of calomel in tropical dysentery, once very prevalent, has the last few years been abandoned. (D. J. L.)

RGANSER, a word originating with Gesner (*Hist. lium*, iii. p. 129) in 1555, and for a long while used glish as the general name for a group of fish eating possessing great diving powers, and forming the *Mergus* of Linnaeus, now regarded by ornithologists Subfamily, *Merginæ*, of the Family *Anatidæ*. The Mergansers have a long, narrow bill, with a sm evident hook at the tip, and the edges of both dibles beset by numerous horny denticulations, whe English the name of "Saw bill" is frequently appl them. Otherwise their structure does not much from the Anatine or Fuligoline type. All the speci a more or less developed crest or tuft on the head. of them, *Mergus merganser* or *cucullator*, *M. serrator*, *albellus*, are found over the northern parts of t World, and of these the first two also inhabit America, which has besides a fourth species, *M. cu* said to have occasionally visited Britain. *M. mer* commonly known as the Goosander, is the largest being nearly as big as the smaller Geese, and the male in breeding attire is a very beautiful bird, consp with his dark glossy green head, rich salmon c breast, and the upper part of the body and wings and white. This full plumage is not assumed t second year, and in the meantime, as well as in th nuptial dress, the male much resembles the female, like her, a reddish brown head, the upper parts g brown, and the lower dull white In this condition th is often known as the "Dun Diver." This species abundantly in many parts of Scandinavia, Russia, S and North America, and of late years has been found so in Scotland, usually making its nest in the stum hollow tree or under a slab of rock. *M. serrator* monly called the Red-breasted Merganser, is a sor smaller bird; and, while the fully dressed male wa delicate line of the lower parts, he has a gorget of mottled with black, below which is a patch of feathers, broadly edged with black The male a times and the female always much resemble the pre It is more numerous than the Goosander, with a sou more southern range, and is not so particular in s a sheltered site for its nest Both these species h bill and feet of a bright reddish orange, while *M.* known as the Smew, has these parts of a lead colo the breeding plumage of the adult male is white, with crescentic markings of black, and the flanks most fully vermiculated the female and male in undress a general resemblance to the other two already de

But the Smew is very much smaller in size, and as is known, it invariably makes its nest in a hollo as ascertained first by Wolley (*Ibis*, 1859, pp. 69 This last habit is shared by *M. cucullatus*, the Merganser of North America, in size intermediate *M. albellus* and *M. serrator*, the male of which i recognizable by his broad semicircular crest, bearing shaped patch of white, and his elongated subscapu white edged with black The conformation of the in the male of *M. merganser*, *M. serrator*, and *M. cu* is very like that of the Duck of the genus *Clangu* *M. albellus* has a less exaggerated developmen resembling that of the ordinary *Fuligulæ*.[1] Fr southern hemisphere two species of *Mergus* hav described, *M. octosetaceus* or *brasilianus*, Vieillot (*N d'Hist Naturelle*, ed. 2, xiv. p. 222; *Gal des*

[1] Hybrids between, as is presumed, *M. albellus* and *glaucion*, the common Golden-eye, have been described and (Embeck, *Isis*, 1831, 360, tab. iii.; Brehm, *Vollst. Naturg. d. Deutschlands*, p. 930; Naumann, *Vog. Deut. Inlands*, vii frontispiece, Kjærbolling, *Journ. für Ornithologie*, 1855, p. 29, *Naumannia*, 1853, p. 327, *Orn. Dan.*, tab. lv tab. 29) under the names of *Mergus anatarius*, *Clangula anan* and *Anas* (*Clangula*) *mergoides*, as though they were ordinar but the remarks of M. de Selys-Longchamps (*Bull. Ac. Sc. B* 1845, pt. ii. p. 354, and 1856, pt. ii. p. 21) leave little room as to their origin, which, when the cryptogamic habit and range of their putative parents, the former unknown to the au named, is considered, will seem to be still more likely.

. p. 209, pl. 283), inhabiting South America, of
ut few specimens have been obtained, having some
resemblance to *M. serrator*, but much more darkly
l, and *M. australis*, Hombron and Jacquemont

e in the Paris Museum procured by the French
the expedition to the Auckland Island. This last
may perhaps be found to visit New Zealand, and
certainly be looked for there.

n associated with the Merganeæ is the genus
tta, the so-called Torrent Duck of South America,
h three species are said to exist, but they possess
tails and have their wings armed with a spur.
er they should be referred to the *Merginæ* or the
turinæ —the Spiny-tailed Ducks proper—is a ques
at further investigation must decide. (A. N.)

RGUI, a district of British Burmah, between 9° 58′
′ 21′ N. lat. It forms the southernmost district of the
erim division, and is bounded on the N. by Tavoy,
S. by Siam, and W. by the Bay of Bengal, with
a of 7810 square miles. Two principal ranges cross
from north to south, running almost parallel to
her for a considerable distance, with the Tenasserim
nding between them till it turns south and flows
h a narrow rocky gorge in the westernmost range
sea. Amongst these mountain ranges and their
ary spurs are several fertile plains, densely clothed
uxuriant vegetation. Indeed, the whole district, from
ter's edge to the loftiest mountain on the eastern
ary, may be regarded as almost unbroken forest, only
are miles being under cultivation. The timber trees
towards the interior, and on the higher elevations,
great size and beauty, the most valuable being teak,
n (*Hopea odorata*), *ka-gnyeng* (*Dipterocarpus tuber-*
), &c. The coast line of the district, studded with
ipelago of two hundred and seven islands, is much
, and for several miles inland is very little raised
sea-level, and is drained by numerous muddy tidal

our principal rivers are the Tenasserim, Le-gnya,
un, and Palouk, the first three being navigable for a
erable distance of their course. Coal is found in the
t on the banks of the Tenasserim and its tributaries.
copper, iron, and manganese are also found in various
of the district.

the no ices of early travellers it appears that Mergui, when
Siamese rule, before it passed to the Burmese, was a rich and
peopled country. On its occupation by the British in
5 it was found to be almost depopulated, the result of
warfare and of the cruelties exercised by the Burmese con-
. At that time the entire inhabitants only numbered 10,000;
6 they had increased to 51,846 (26,767 males and 25,079
s). Classified according to religion, there were Buddhists,
; Mohammedans, 2513, Hindus, 353, Christians and others.
The district contains only one town (Mergui) with more than
habitants. Only 73 square miles of the district area were
cultivation in 1876, but this area is steadily though slowly
ing. The principal manufactures are sugar-boiling and tin-
ng. Mergui carries on a flourishing trade with Rangoon,
, and the Straits Settlements. The chief exports consist
, rattans, torches, dried fish, areca nuts, sesamum seeds,
es, sea-slugs, edible birds' nests, and tin. The staple imports
e goods, tobacco, cotton, earthenware, tea, and sugar. The
l revenue in 1876 amounted to £18,208. The climate is
ainly healthy, the heat due to its tropical situation being
ated by land and sea breezes. The rainfall in 1876 amounted
inches. The prevalent diseases are simple and remittent
, bronchitis, rheumatism, and small-pox.

MERGUI, chief town of the above district, is si
on an island at the mouth of the Tenasserim river.
population (10,731 in 1876–77) consists of many r
Talaings, Burmese, Malays, Bengalis, Madrasis, Si
and Chinese. Considerable trade is carried on with
Burmese ports and the Straits Settlements. The h
admits vessels drawing 18 feet of water.

MÉRIDA, a city of 7390 inhabitants (1877),
province of Badajoz, Spain, lies about 36 miles
eastward from Badajoz, on the Madrid and Badajo
on a small eminence on the right bank of the Gua
It is connected by a branch line of rail with Llere
the south-east. The population is mostly agricu
The city owes its interest entirely to its Roman re
which are numerous and extensive. Of these one
most important is the bridge of 81 arches of granite,
by Trajan; it is 2575 feet long, 26 feet broad, and
above the bed of the river; it was unfortunately se
injured during the siege of Badajoz in 1812.
colossal wall that formerly surrounded the town a

RIMÉE, Prosper (1803 1870), novelist, archaeo
essayist, and in all these capacities one of the
t masters of French style during the century, was
Paris on September 28, 1803, and died at Cannes
23d of the same month sixty-seven years later,
lived just long enough to know that ruin was
ning France. Not many details have been published
rence to his family, but his father seems to have
man of position and competence. Merimee had
blood in his veins on the mother's side, and was
considered, at least in France, to look and behave
ike an Englishman than a Frenchman. He was
d for the bar, but entered the public service instead.
g man at the time of the romantic movement, he
s influence strongly, though his peculiar tempera
revented him from joining any of the cénacles of the
This temperament was indeed exhibited by the
rm and nature of the works in which he showed
nence of romanticism. Nothing was more prominent
the romantics than the fancy, as Merimée himself
for "local colour," the more unfamiliar the better.
é exhibited this in an unusual way. In 1825 he
ed what purported to be the dramatic works of a
lady, Clara Gazul, with a preface stating circumstan-
ow the supposed translator, one Joseph L'Estrange,
t the gifted poetess at Gibraltar. This was followed
still more audacious and still more successful
erie. In 1827 appeared a small book entitled *La*
(the anagram of Gazul), and giving itself out
nslated from the Illyrian of a certain Hyacinthe
novich. This book, which has greater formal merit
lara Gazul, is said to have taken in Sir John Bow
competent Slav scholar, the Russian poet Poushkin,
me German authorities, although not only had it no
l, but, as Mérimée declares, a few words of Illyrian
book or two of travels and topography were the
's only materials. In the next year appeared a short
ic romance, *La Jacquerie*, in which all Mérimée's
eristics are visible his extraordinary faculty of
nd historical colour, his command of language, his
ony, and a certain predilection for tragic and terrible
s which was one of his numerous points of contact
e men of the Renaissance This in its turn was
d by a still better piece, the *Chronique de Charles*
hich stands towards the 16th century much as the
rie does towards the Middle Ages. All these works
a certain extent second hand, being either directly
d or prompted by a course of reading on a particular
. But they exhibited all the future literary qualities
author save the two chiefest, his wonderfully severe
nost classical style, and his equally classical solidity
atuesqueness of construction. For the latter there
t much opportunity in their subjects, and the former
d a certain maturity and self-discipline which
Mérimée had not yet given to himself. These
however, displayed fully in the famous Corsican s
Colomba, published in the momentous year 1830,
all things considered, is perhaps Mérimée's best tale

He had already obtained a considerable posit
the civil service, and after the revolution of July
chef de cabinet to two different ministers. He wa
appointed to the more congenial post of inspec
historical monuments. Merimee was a born archae
combining linguistic faculty of a very unusual kin
the accurate scholarship which does not always acco
it, with remarkable historical appreciation, and with a
love for the arts of design and construction, in the
of which he had some practical skill. In his
capacity he published numerous reports, some of
with other similar pieces, have been republished
works. He also devoted himself to history proper
the latter years of the July monarchy, and pu

be said presently, and for two correspondences, wh
not the least of his literary achievements, while the
an extraordinary interest of matter. One of these

letters which have been published as *Lettres à une* *ne*, the other of the letters addressed to Sir Antonio , the late librarian of the British Museum. Various, idle and rather impertinent, conjectures have been as to the identity of the *inconnue* just mentioned. fficient to say that the acquaintance extended over years, that it partook at one time of the character , at another of that of simple friendship, and that ee is exhibited under the most surprisingly diverse most of them more or less amiable, and all interest- The correspondence with Panizzi has somewhat less al interest Mérimée made the acquaintance origin a suggestion that his correspondent should buy for useum some MSS. which were in the possession of al's sister, and for some year it was chiefly confined respondence. But Mérimée often visited England, he had many friends (among whom the late Mr of Glengarry was the chief), and certain similarities drew him closer to Panizzi personally, while during the empire the two served as the channel for a of unofficial diplomacy between the emperor and English statesmen. These letters are full of shrewd s on the state of Europe at different times. Both abound in gossip, in amusing anecdotes, in sharp critcism, while both contain evidences of a cynical belief-au or Swiftian humour which was very strong mée. This characteristic is said to be so prominent rrespondence with another friend, which now lies in ary at Avignon, that there is but little chance of its ing printed A fourth collection of letters, of much extent and interest, has been printed by M. Blaze y under the title of *Lettres à une autre Inconnue*. latter years of his life Mérimée suffered very much ll health. It was necessary for him to pass all his at Cannes, where his constant companions were two English ladies, friends of his mother. The terrible und him completely broken in health, and anticipating ast for France He lived long enough to see his fears d and to express his grief in some last letters, and d on September 23, 1870

mée character which has been unwarrantably slandered e to whom political differences or his sarcastic intolerance e in literature made him obnoxious was a peculiar and in spect an unfortunate one, but by no means unintelligible, hap in a minor degree not uncommon Partly by tempera- artly it is said owing to some childish experience, when he ed there he had been duped and determined never to be so not least owing to the example of Beyle, who was a friend ously, and of whom he saw much, Mérimée appears at a atively have imposed upon himself as a duty the ance of an attitude of sceptical indifference and sarcastic n He certainly succeeded Although, as has been said, a singularly warm and affectionate feelings, he obtained the of being a cold hearted cynic, and, although he was both dent and disinterested, he was abused as a hanger on and ter of the imperial court Both imputations were wholly ved, and indeed were prompted to a great extent by the ent felt by the literary equal on the other side at the cool with which he met them But he deserved in some of the well a many of the good sense of the term the phrase which e applied to him of a man of the Renaissance. He had the artisanship and amiability toward friends and the scorpion- ne for his foes, he had the ardent delight in learning and ly in matters of art and belle lettres, he had the scepticism, nptuousness, the curious delight in the contemplation of the , which marked the men of letters of the humanist period em he was a man of the world, and a man who without any s liked a king's palace better than a philosopher's hovel em he had an acute judgment in matters of business, and like singular consciousness of the nothingness of things Even his work has this Renaissance character It is tolerably ex amounting to some seventeen or eighteen volumes, but its not great for a life which was not short and which was d at least nominally in little else About a third of it con- the letters already mentioned, which will always be to ho delight in personal literature the most attractive part, ch, though in a fragmentary fashion, are really important as throwing side lights on history. Rather more than another consists of the official work which has been already allude reports, essays, short historical sketches, the chief of which a history of Pedro the Cruel, and another of the curious pr known in Russian story as the false Demetrius. Some literary essays, such as those on Beyle, on Turguenief, &c. a personal element enters, are excellent. Against others and the larger historical sketches admirable as they are - M. criticism that they want life has some force. They are, ho all marked by Mérimée's admirable style, by his sound and a scholarship his strong intellectual grasp of whatever he h his cool unprejudiced views, his marvellous faculty of design proportioning the treatment of his work It is, however, remaining third of his work, consisting entirely of tales o narrative or in dramatic form, and especially in the former, t full power is perceived. He translated a certain number of chiefly from the Russians, but his fame does not rest on th his already-mentioned youthful supercheries, or on his late dramatic works There remain about a score of tales exten point of composition over exactly forty years, and in lengt that of *Colomba*, the longest, which fills about one hundred a pages, to that of *L'Enlèvement de la Redoute*, which fills p a dozen They are unquestionably the best things of the written during the century, the only *nouvelles* that can ch comparison with them being the very best of Gautier, and two of Balzac The motives are sufficiently different In *C* and *Mateo Falcone*, the Corsican point of honour is drawn *Carmen* (written apparently after reading Borrow's Spanish the gipsy character; in *La Vénus d'Ille* and *Lokis* (two finest of all), certain grisly superstitions, in the former c known in a milder form as the ring given to Venus, in the variety of the were-wolf fancy *Abbon Gaillot* is a singula full of sarcastic pathos on popular morality and religio *Chambre Bleue*, an 18th century *conte*, worthy of Crébil grace and wit, and superior to him in delicacy, *The Captur Redoubt* just mentioned is a perfect piece of description; *Arbara* is again satirical; *La Double Méprise* (the author which was objected to Mérimée when he was elected Academy) is an exercise in analysis strongly impregnate the spirit of Stendhal, but better written than anything writers These stories, with his letters, assure Mérimée's p literature at the very head of the French prose writers of the c He had undertaken an edition of Brantôme for the Bibli Elzevir one, but it was never completed.

Mérimée's works have only been gradually published si death The latest, *The Letters to Panizzi*, which have a peared in English, bears date 1881 There is as yet no u or handsome edition, but almost everything is obtainable collections of MM. Charpentier and Calmann Lévy. (G.

MERINO. See SHEEP and WOOL.

MERIONETH (Welsh *Meirionydd*), a maritime c of North Wales, is bounded N. by Carnarvon and De S.E. by Denbigh and Montgomery, and W. by Ca Bay It is triangular in shape, its greatest length east to south-west being 15 miles, and its greatest b north west to south east about 30 miles. The area is 3 acres, or about 600 square miles. Next to Carnarvon outh is the most mountainous county in Wales. scenery is less bold and striking than that of Carn it excels it in richness, variety, and picturesque l Its lofty mountains are interpenetrated by dark dee or smiling vales. The outlines of its rugged cra softened and adorned by rich foliage. The sea vie frequently fine, and rivers, lakes, and waterfalls romantic charm to the valleys. The highest summ the county are the picturesque Cader Idris (which into three peaks, one, Pen y Gadair, having an alti 2914 feet), Aran Fawddwy (2955), Arenig-fawr (Moel wyn (2566), Rhobell-fawr (2360). The finest are those of Dyfi, Dysyni, Talyllyn, Mawddach, and nnog. The river Dyfrdwy or Dee rises 10 miles nort of Bala, and, after passing through Bala Lake, flows east by Corwen to Denbighshire. The Dyfi rises in lake near Aran Fawddwy, and expands into an of Cardigan Bay. The Mawddach or Maw, fro north of Aran Fawddwy, has a course of 12 miles west, during which it is joined by several other s The Dwyryd and other streams unite in formi estuary of Traeth Bach. The finest waterfalls a

y Glyn near Corwen, Rhaiadr Du, and Pistyll he latter 150 feet high. The lakes are very us, but small, the largest being Bala Lake, or Pim (in Welsh, Llyn Tegid, fair lake), 4 miles long by , and Llyn Mwyngil (lake in a sweet nook) in the Talyllyn. Both are much frequented by anglers. ount of frequent indentations the coast-line is about les long. Sandy beaches intervene between the shores. Frequent shoals and sandbanks render ion very dangerous. There are only two harbours rtance, Barmouth and Aberdovey.

ountain tract of the county 15 miles from north to by 10 from east to west, stretching from the coast is of the Cambrian age, composed of grits, quartzose, tes, and comprising the Merionethshire anticlinal. act is enclosed on the north, east, and south by the an, Lingula, Tremadoc, and Arenig beds, which are by numerous dykes and intrusive masses, mostly one. Rhobell fawr is one of the greatest igneous in the whole area of the Lingula beds. The Arenig e interstratified with and overlaid by accumulations anic a hes, felspathic traps, or lava flows, which e ragged heights of Cader Idris, the Arans, the , Manod, and Moelwyn, and these are in turn by the Llandeilo and Bala beds, the latter mem- Bala limestone. Extensive slate quarries are near Festiniog, mostly underground, in strata of ndeilo age, giving employment to about 1000 men. ead, copper, and manganese have been obtained in places.

te and Agriculture.—The climate varies much with the , in some places being bleak and cold, and in others re- y equable and genial. At Aberdovey it is proverbially d the myrtle grows in the open air. All attempts to intro- its have proved abortive in most parts of the county. The enerally thin and poor, with fertile tracts in the valleys. portion of the moss has been reclaimed within late years. ding to the agricultural returns for 1882, there were 154,106 considerably less than half the total area, under cultiva- Of this as much as 119,133 acres were permanent pasture, 55 under rotation grasses. Of the 17,312 acres under corn 1,232 were under oats and 1807 under barley. Potatoes 2392 acres, and turnips only 1196 acres. The area under xtended to 15,049 acres.

otal number of horses in 1882 was 6088. A breed of e peculiar to this county and Montgomeryshire. The of horned cattle and dairy-farming are largely carried on, number of cattle (37,643) is considerably under the average s generally. On the other hand the number of sheep in s 400,553, a larger number than in any other county of and much beyond the general average in the principality. e a small hardy breed, which grow heavy fleeces. Goats the loftier crags.

ding to the latest return the number of proprietors was 1695, ng 303,374 acres, with a gross annual value of £183,253. Of ers 1044, or 62 per cent., possessed less than 1 acre, the extent of the properties being 189 acres, and the average r acre a little over 12s. There were ten proprietors who d over 5000 acres, viz., Sir W. W. Wynn, 20,295; R. J. L. 7,718; T. P. Lloyd, 16,975; Mrs. Kirkby, 13,410; Hon. Wynn, 10,501, A. J. G. Corbet, 9347; Sir E. Buckley, W. E. Oakeley, 6018, W. O. Gore, 5497, and R. M. s, 5701.

ufactures.—Woollen goods are manufactured in various especially at Dolgelly. They are principally coarse druggets, ets, and flannels. The knitting of stockings was a great y at the close of last century, the value of the sales at Bala stimated at from £17,000 to £19,000 annually.

ays. The Cambrian Railway skirts the coast from Port o Aberdovey. At Barmouth Junction a branch of the same to Dolgelly, where it is joined by a branch of the Great n Railway. Another branch of the Great Western unites d Festiniog, and the latter place has railway connexion both anduduno Junction and with Portmadoc.

inistration and Population.—Merionethshire comprises five ds and thirty-three civil parishes. It has one court of quarter , and the number of petty sessional divisions is six. Eccles- it is partly in the diocese of Bangor, partly in that of St The county returns one member to parliament. There is no municipal or parliamentary borough. The towns return 1881 as urban sanitary districts are Bala (1653), Barmouth (Dolgelly (2457), Festiniog (11,272), and Towyn (3363). 1801 the population has nearly doubled. From 29,506 in tha it had increased in 1851 to 38,963, in 1871 to 46,598, and in to 54,793, of whom 27,576 were males, and 27,217 females.

History and Antiquities.—Originally Merioneth belonged territory of the Ordovices, and under the Romans it was in *Britannia Secunda*. There are many Celtic, Roman, and eval remains. Caer Drewyn on the Dee, near Corwen, was a camp. There are numerous cromlechs in various parts of the especially near the sea-coast. The *Via Occidentalis* of the R passed through Merioneth from south to north, and at T y-Mur was joined by a branch of the South Watling Stre Castell Tomen y Mur being supposed to be identical wit Roman station of Heriri Mons. The immense ruin of Ca Bere was originally one of the largest castle in Wales, but l cupied since the time of Edward I. During the War Roses the castle of Harlech, still a fine ruin, was held Lancastrians, and was the last in Wales to surrender. Of astical remains the most important is Cymmer Abbey, founded Cistercians in 1198, a very fine ruin containing architect various periods from Norman to Perpendicular. There are one interesting old churches.

MERLIN. See FALCON.

MERMAIDS AND MERMEN, in the popular myth of England and Scotland, are a class of beings more completely akin to man, who have their dwelling in th but are capable of living on land and of entering into relations with men and women.[1] They are easily iden at least in some of their most important aspects, wit Old German Merminnin or Meerfrau, the Icelandic Ha Margygr, and Marmennill (mod. Marbendill), the I Hafmand or Maremmd, the Irish Merrow or Mer the Marie Morgan of Brittany and the Morforw Wales;" and they have various points of resembla the vodyany or water-sprite and the rusalka or stream of Russian mythology. The typical mermaid (w much more frequently described than the merman) h head and body of a woman, usually of exceeding love but below the waist is fashioned like a fish with scal fins. Her hair is long and beautiful, and she is represented, like the Russian rusalka, as combing i one hand while in the other she holds a looking glass other times, like the rusalka, she is seen engaged more prosaic occupation of washing or beating clothes this, as, for example, in Hugh Miller's terrible Loch legend, is a sign of some impending calamity. For at least a mermaid may become to all appearance a nary human being, and from a very striking Irish ("The Overflowing of Lough Neagh and Liban the maid," in Joyce's *Old Celtic Romances*) it is evident human being may also for a time be transformed mermaid.

The mermaid legends, both English and other, grouped as follow:—A. *A mermaid or mermaids voluntarily or under compulsion reveal things that are to happen*. Thus the two mermaids (merewip) Hae and Sigelint, in the *Nibelungenlied*, disclose his course to the hero Hagen, who, having got poss their garments, which they had left on the shore, c them to pay ransom in this way. According to Re a mermaid appeared to a peasant of Samsoe, foreto birth of a prince and moralized on the evils of

[1] The name *mermaid* is compounded of the A.S. *mere*, a l *maegd*, a maid; but though *mere-wif* occurs in Beowulf, *mer* not appear till the Middle English period (Chaucer, *Rom. R Rose*, &c.). In Cornwall the fishermen say *merry maids* and *men*. The connexion with the sea rather than with inland appears to be of later origin. "The Mermaid of Martin Roby's *Traditions of Lancashire*, vol. ii., is an example of th force of the word; and such "mere-women" are known country folk in various parts of England (*e.g.*, at Newport in shire, where the town is some day to be drowned by the agency).

[2] See Rhys, "Welsh Fairy Tales," in *Cornhill Magazine*, 1881

, &c. (*Kong Frederichs den andens Kronike*, agen, 1680, p. 302). B *A Mermaid imparts tural powers to a human being.* Thus in the l story of "The Old Man of Cury" (in Hunt's *Romances of the West of England*, 1871) the old stead of silver and gold, obtains the power of doing his neighbours by breaking the spells of witchcraft, away diseases, and discovering thieves. John he Cromarty shipmaster, was more selfish, his s three' being that neither he nor any of his should perish by the sea, that he should be unin dly successful in everything he undertook, and that ly who scorned his love should scorn it no more. *ermaid has some one under her protection, and for lone to her ward exacts a terrible penalty.* One of t and most detailed examples of this class is the f the "Mermaid's Vengeance" in Mr Hunt's book quoted D *A mermaid falls in love with a human lives with him as his lawful wife for a time, and then, nuptial being unwittingly or intentionally broken by him, to her true home in the sea.* Here, it its mermaid accepted, the typical legend is undoubtedly that *sent*, which, being made the subject of a full-fledged by Jean d'Arras, became one of the most popular oks of Europe, appearing in Spanish, German, and Bohemian versions. Melusina, whose name e a far off echo of the Mylitta (Venus) of the ians, was married to Raymond of Lusignan, and g afterwards proudly recognized as one of their s by the Luxembourg, Rohan, and Sassenaye s, and even by the emperor Henry VII. Her story found in Baring Gould's *Myths of the Middle Ages*. *ermaid falls in love with a man, and entices him to live with her below the sea; or a merman wins the or captures the person of an earthborn maiden* m of legend is very common, and has naturally favourite with poets Macphail of Colonsay fully rejects the allurements of ermaid of rekin, and comes back after long years of trial to d of Colonsay.[1] The Danish ballads are especially the theme; as "Agnete and the Merman," an ante- of Matthew Arnold's "Forsaken Merman"; the ittul Merman, or Marstig's Daughter"; and the detailed story of Rosmer Hafmand (No. 49 in)

elation to man the mermaid is usually of evil issue of evil intent. She has generally to be bribed or led to utter her prophecy or bestow her gifts, and r as wi a paramour she brings disaster in her In it elt her sea life is often represented as one of delight, but at other times a mournful mystery dines brood over it. The fish tail, which in popular orm the characteristic feature of the mermaid, is of nitary importance; for the true Teutonic id probably a remnant of the great cult of the had no fish tail' and this symbolic appendage in such remote mythological regions as to give no historical connexion The Tritons, and, in the epresentations, the Sirens of classical antiquity, the rian Dagon, and the Chaldean Oannes are all well- examples; the Ottawas and other American Indians heir man fish and woman fish (Jones, *Traditions of rth American Indians*, 1830), and the Chinese tell not unlike our own about the sea women of their rn seas (Dennis, *Folklore of China*, 1875)

st historical instances of the appearance or capture of mermaids are common enough,[3] and serve, with the fre use of the figure on signboards and coats of arms, to how thoroughly the myth had taken hold of the p imagination.[4] A mermaid captured at Bangor, o shore of Belfast Lough, in the 6th century, was ne baptized, but admitted into some of the old calendar saint under the name of Murgen (*Notes and Q* Oct. 21, 1882); and Stowe (*Annales*, under date relates how a man fish was kept for six months and in the castle of Orforde in Suffolk. As showing legendary material may gather round a simple the oft told story of the sea-woman of Edam is p larly interesting. The oldest authority, Joh. Gerbr a Leydis, a Carmelite monk (*ob.* 1504), tells (*A* &c., Franktort, 1620) how in 1403 a wild w came through a breach in the dike into Purmerlake being found by some Edam milkmaids, was ultim taken to Haarlem and lived there many years. N could understand her, but she learned to spin, an wont to adore the cross. Oeka Scharlensis (*Chron Frysland*, Leeuw., 1597) reasons that she was not because she could spin, and she was not a woman b she could live in the sea; and thus in due cour got fairly established as a genuine mermaid. Vo who has carefully investigated the matter, enumerate writers who have repeated the story, and shows th older ones speak only of a woman (see "Beschr. v zoogen. Meermin der stad Haarlem," in *Verh. van d Maatsch. van K. en Wet.*, part 23, No. 1786). As stuffed mermaids which have figured from the days tholomew Fair downwards, it is enough to mentio exhibited in the Turf Coffee-house, London, in and carefully drawn by Cruikshank (compare Cha *Book of Days*).

The best account of the mermaid-myth is in Baring *Myths of the Middle Ages*. See also, besides works alread tioned, Pontoppidan, who in his logically credulous way much matter to prove the existence of mermaids; Maillet *ued*, Hague, 1755; Grimm, *Deutsche Mythologie*, i. 4 *Altdan Heldenlieder*, 1811; Waldron's *Description* and *Hist and Stat Acc of the Isle of Man*, Folklore Society's vol. ii.; Napier, *Hist and Trad. Tales connected with the Scotland*; Sebillot, *Traditions de la Haute Bretagne*, 18 *Contes des Marins*, 1882 (H. A

MEROE, in classical geography (Strabo, xvii. 2, 2; ii. 73, v. 10; Ptol., p. 201), was the metropolis of Æt situated on an island of the same name between th and the Astaboras (Atbara). The "island" is o inaccurate name for the fertile plain between t rivers. This Meroe, first mentioned by Herodotus *sq.*), succeeded an older Ethiopian kingdom of Napat down the Nile, originally subject to and civilize Egypt, but which afterwards became independent an sent forth an Ethiopian dynasty to reign in Egypt, to the So and Tirhaka of the Bible belonged (see Ethi The name of Meroe in the form Merawi is now g Napata. The later Meroe retained its independence Egypt fell under foreign sovereigns. Diodorus describes it as entirely controlled by the priesthoo native prince Ergamenes destroyed the sacerdotal c the time of Ptolemy II. [4] See the paper in *Journ. Brit. Arch. Ass.*, xxxviii., 1882, Cumming, who points out that mermaids or mermen occur in of Earls Cadogan, Howth, and Sandwich, Viscounts Boyne an Lord Lyttleton, and Scott of Abbotsford, as well as in thos Ellis, Byron, Phené, Skellington, and other families. The heralds represent the creatures with a single tail, the Fr German heralds frequently with a double one.

n Candace in Augustus's time when the Romans Petronius advanced to Napata. Meroe was visited ek merchants; and the astronomical expedition of henes determined its latitude with great accuracy. loring party in the reign of Nero found that the below Meroe, formerly the site of many towns, come almost wholly waste (Pliny, vi. 29). From to the 14th century of our era the Christian te) realm of Dongola occupied the place of the older n. The ruins of Meroe and Napata were fully d by Lepsius in 1841, and the monuments are l in his *Denkmäler*.

RSEBURG, the chief town of a district of the same the Prussian province of Saxony, is situated on r Saale, 10 miles to the south of Halle and 17 to t of Leipsic. It consists of a quaint and irregularly ld town, with two extensive suburbs, and contains rches and several schools and charitable institutions. thedral is an interesting old pile, with a Romanesque the 11th, a transept of the 13th, and a Late Gothic the 16th century. Among its numerous monuments of Rudolph of Swabia, who fell in 1080 in an ter with his rival Henry IV. It contains two gs by Lucas Cranach. Contiguous to the cathedral Gothic chateau, formerly the residence of the Saxon and the bishops of Merseburg. The town house, the ice, and the "standehaus" for the meetings of the ial estates are also noteworthy buildings. The ies of Merseburg consist of the manufacture of card- and coloured paper, dyeing, glue-boiling, machine-, calico-printing, tanning, and brewing. Its popu- n 1880 was 15,205.

burg (*i.e.*, "march-town") is one of the oldest towns in y. From the 9th century down to 1007 it was the capital ntship of its own name, and from 968 to 1543 it was the seat op. In the 10th, 11th, and 12th centuries it was a favourite e of the German emperors, and at this time its fairs enjoyed ortance afterwards inherited by those of Leipsic. The town eatedly visited by destructive conflagrations in the 14th to turies, and also suffered severely during the Thirty Years' From 1656 to 1738 it was the residence of the dukes of Saxe- rg. The great victory gained by the emperor Henry I. Huns in 933 is believed to have been fought on the Keusch- r Merseburg.

RTHYR TYDFIL, or MERTHYR TYDVIL, a parlia- y borough and market-town of Glamorganshire, Wales, is situated in a bleak and hilly region on the Taff, and on several railway lines, 25 miles north- vest of Cardiff and 30 east-north-east of Swansea. wn, which consists principally of the houses of work s for the most part meanly and irregularly built, and time, on account of its defective sanitary arrange was frequently subject to epidemics of great severity. recent years great improvements have taken place, e town now possesses both a plentiful supply of ater and an excellent system of sewage. There are ne good streets with handsome shops, while in the s there are a number of private residences and villas ed by the wealthier classes. Apart from its extensive d steel works, the town possesses no feature of t. It is situated in the centre of the South Wales sin, and the rich coal-mines in the vicinity supp acilities for the iron industries. At Merthyr Tydfil, is said to have received its name from the martyr a British saint Tydfil, there were smelting-works ry early period, but none of any importance until From about forty years ago until 1875 the manufac- bar iron developed with great rapidity, but since he production of steel has largely taken its place. orough returns two members to parliament. The tion of the urban sanitary district in 1871 was , and in 1881 it was 48,857; the population of the parliamentary borough, which includes the parish of dare and parts of the parishes of Llanwonno and M Tydfil and of Vainor (Brecon), and has an area of acres, was in the same years 97,020 and 91,347.

MERV, MERU, or MAOUR,[1] a district of Central situated on the border-land of Iran and Turan.

The oasis of Merv lies in the midst of a desert, in 37° 30′ N. lat. and 62° E. long. It is about 250 from Herat, 170 from Charjui on the Oxus, 360 Khiva, and 175 from Gawars, the nearest point i newly acquired (1881) Russian territory of Akhal.

The great chain of mountains which, under the n Paropamisus and Hindu-Kush, extends across the continent from the Caspian to China, and forms t of ethnic demarcation between the Turanian and Germanic races, is interrupted at a single point; that is on the same longitude with Merv. Through or n

present inhabitants of the district are Turcomans
Tekke tribe, who, like the other tribes inhabiting
mania, enjoyed until the approach of the Rus ians
independence, and acknowledged allegiance to no
; paying tribute when shocked out a miserable existen
trade of pre datory raids, and in bad times pillaged
neighbouring and equally barbarous states, to whose
, they were in turn subjected.

In the year 1869, the date of the establishment of
an military settlement at Krasnovodsk on the ea t
of the Caspian, the wave of Russian conquest has
ily swept eastwards along the northern frontier
s until it has for the moment stopped at the outer-
border of the Akhal Turcoman country, which was
nated in 1881 by Russia as the result of the defeat
tribe at Geok Tepe. Among the districts still
east, to which the Russians give the name of
n Turcomania, is that of the Merv Tekke Turcomans,
n of the Akhal Te e, the most recent of Russia's
s. The district of the Merv Tekkes may be taken
that included between the lower Murghab below
n, where the river enters the plain, and the Persian
r from Sarakhs to Chawars.

ference to the map will show the strategical import-
of this district, situated at the point of meeting of
nes, of which one is the strategic line of Russian
e on Herat from Krasnovodsk to Sarakhs, and the
the strategic line of advance on the same place from
end through Bokhara. The capital of the district
reover, the cross-ing point of the Herat-Khiva and
d Bokhara trade routes.

sequently this district, a solitary oasis in a vast
, guarantees to its possessor the command of an
tant avenue between north and south, and, in the
of its falling into Russian hands, will give that power
ition a valuable link in the chain of connexion
ee her recent acquisitions on the Persian frontier
here in Turkestan, the forging of which has been
tently advocated by Russian writers for years past.
f these, Colonel Vonnikoff, frankly admits that it is
litical results "the consolidation of friendly relations
the Turcomans" and not commercial interests
s, that are primarily looked to, and openly states
he forward movement in Central Asia "cannot end
wise than by the annexation to Russia of the whole
tan."

ether by design or by the force of circumstances, the
mendations of those writers have been translated into
and Russia with her advanced post at Askabad is
ithin 100 miles of Herat, which Sir Henry Rawlinson
ates as the key of India. The occupation of the
Tekke country would bring Russia to within 250
of Herat. From Askabad she is in connexion with
aspian by a good line of communication, part of which
the sea to Kizil Arvat) is by rail; and hence facilities
are offered for bringing up not only the resources
Caucasus but of the whole of European Russia.
Russian troops are within 400 miles of Herat, the I
troops at Quetta are more than 500 miles from Hera

These remarks serve to explain the very n
suspicion with which Great Britain has regarde
occupation one after another of important strat
points along that route by which alone Russia can
at India, the same line by which Napoleon medit
Russo French invasion in the early part of this centu

In the matter of Merv and the neighbouring Turcoman d
diplomacy has not been idle. As early as 1869, when an
change of opinions was taking place between the Russia
British Governments with respect to the demarcation of a
zone between the two empires, Great Britain objected
Russian proposal that this zone should be Afghanistan, "t
of the next approach to India that would be thereby affor
Russian troops from the direction of the Kara-kum, the hom
Turcomans, of which Merv is the central point. In the fo
year a Russian diplomatist remarked to the British embass
St Petersburg, when discussing the Afghan frontier, that ge
would be requi tracing a line from Khoja Saleh on th
to the south, as Merv and the country of the Turcoman- w
coming "commercially important." About the same time
intimated that, if the amir of Afghanistan claimed to e
sovereignty over the Tekkes, his pretension could not be reco
After the Russian campaign against Khiva in 1873, and t
frequent operation against the Turcomans, the English
secretary early in 1874 called attention, "to the terms expre
the amir of Afghanistan as to the complications in which he
become involved with Russia were the result of a Russian
dition against Merv to be to drive the Turcomans to take re
the province of Badghees in Herat." In reply to this co
cation Prince Gortschakoff repeated the assurance that the i
Government "had no intention of sending any expedition
the Turcomans, or of occupying Merv." In 1875 the opera
General Lomakin on the northern frontier of Persia led to re
tition being made by the British ambassador at the cou
Petersburg. To these Russia replied that the czar had no
tion of extending his frontiers on the side of Bokhara or
side of Krasnovodsk. Notwithstanding the oft-repeated ass
to the contrary, large annexations have been since made in
mania by the Russians, and these proceedings, clearly in
the persistent prosecution of a concerted plan, have naturally
to disturb the harmonious relations which should subsist
the two great civilizing powers of the East.

Settlements and Inhabited Centres.—Of towns o
villages, fixed centres of habitation, there are no
cording to Mr O'Donovan, the latest European t
to Merv. The present political and military cap
Merv is Koushid Khan Kala, a fort which serves ra
a place of refuge against sudden attacks than as a
tion. It is situated on the east bank of the most w
branch of the Murghab, about 25 miles below the
Porsa Kala. In form it is oblong, measuring $1\frac{3}{4}$ mi
by $\frac{3}{4}$ mile broad, is constructed entirely of earth, r
on the exterior slope with sun dried brick; the ra
are 40 feet high, and are 60 feet at the base. The
built in a loop of the river, which protects it on two
between it and the river is an "obah," or nomad vi
huts and tents, some thousand in number, disposed i
but there is no town or settlement.

Twenty-five miles east of Koushid Khan Kala
ruins of the Greek city of Antiochia Margiana, s
traces of a high civilization. According to Strabo
the Merv oasis at this period was surrounded with
measuring 1500 stadia (185 miles). Mr O'Donovan
the trace of the fort of Iskander to have been quadra
with a length of side of 900 yards. This was proba
fort built by Alexander, about 328 B.C., on his retu

the time of the visit of Burnes, Abbott, Shakespear,
Taylour Thomson, about the fourth decade of the
y, Merv was under the jurisdiction of Khiva, and
dministrative centre was at Porsa Kala, where the
s situated. This place is now also a waste of mud
uninhabited.

ers.- Heri rud (or Tejend, as the river is
l below Sarakhs) runs a course of some 280 miles
Afghan borders. On reaching the Persian from
t turns north and forces a channel through the
tain chain near Sarakhs. Beyond Sarakh the river
rcoman on both banks, runs close to the Khelat
tains, and in the latitude of Askabad loses itself
arshes formed by the spring floods. It is probably
chus of ancient geography, which watered Nissa, once
pital of Parthia, and joined the Oxus just before
tter river disembogued into the Caspian (Rennell's
lotus). The Tejend is fordable at all points below
hs except in the early spring after the melting of the
s. On the road from Meneh to Merv the river is
sh, 50 yards wide and 4 feet deep in February. The
bed is sunk 12 to 15 feet below the level of the
nding country, and has immense quantities of drift
on its banks; trees and luxuriant herbage clothe the
diate borders. At midsummer the river runs nearly
and does not reach Sarakhs. The Kashaf-rud, which
near Meshed, is one of its chief affluents.

e Murghab takes its rise in the northern slopes of the
paniisus, and runs parallel to the Heri rud at a distance
miles from it. On this river lies the plain or oasis
ery, irrigated by means of an elaborate system of dams
anals cut from the main river. Beyond the limits
oasis the Murghab "hides its streams in the sand,"
the Tejend. The river at Porsa Kala (near the
ipal dam) is 80 yards wide, at Koushid Khan Kala 30
yards wide. In summer it is much swollen by the
ng of the snows, and its stream is then barely fordable.
water is yellow in colour from suspended matter.
rmerly a great deal of the country, now a waste,
en the two rivers was also cultivated by the agency
ter derived from canals cut from the Tejend. These
s extended to Kucha Kum in the desert, rendering
ourney between the two rivers much easier than in the
nt day. From the Murghab was also cut, among
s, the Kara-i-ab canal, which ran for a distance of 10
towards the Tejend. Recent explorers affirm that there
reason why these canals should not be again filled
those rivers, when the intervening country, "an argil-
us expanse" (O'Donovan), would become culturable.

mmunication.—Merv is surrounded on all sides by desert. On
rth, west, and east this desert is sandy and arid; water is
dingly scarce, the wells being sometimes 60 or 70 miles apart.
easily choked. To the south of Merv, between the rivers
ab and Tejend, there are traces of past cultivation, of irrigating
, and of considerable settlements. Between the Tejend and
ad the road lies through a populous well-cultivated country
an territory) by way of Kahka and Lutfabad.

There are no roads in Merv,—nothing but mere tracks.
wide and deep irrigating canals have to be crossed, bridges
and bad. The inhabitants cross by inflated skins.

The following tracks lead to the Persian frontier from Me
viâ Mahmur or Chungul to Lattabad eight days on camel

n Sanjar of the same house, towards the middle of the 11th
Merv was overrun by the Turcomans of Ghuz, and the
was reduced to a state of misery and desolation. These
ans, the ancestors of the present tribes of Turcomania,
obably introduced into the country by the Seljukian Turks
ary colonists. They formed the van of their armies, and
efficient service so long as the dynasty lasted, and after-
ok part in the wars of Tamerlane.

1 Merv opened its gates to Toulai, son of Jenghiz, khan
Mongols, on which occasion the inhabitants, to the number
000, are said to have been butchered. From this time
Merv, which had been the chief city of Khorasan, and
ularly supposed to contain a million inhabitants, com-
to languish in obscurity. In the early part of the 14th
Merv was again the seat of a Christian archbishopric of the
Church. On the death of the grandson of Jenghiz khan
Merv became included in the possessions of Toghluk Timur
(Tamerlane), in 1380. In 1505 the decayed city was occup
the Uzbeks, who five years later were expelled by Ismail
the founder of the Sufiavean dynasty of Persia. Merv ther
ward remained in the hands of Persia until 1787, when
attacked and captured by the emir of Bokhara. Seven
later the Bokharians razed the city to the ground, broke dow
dams, and converted the district into a waste. About 17
Sarik Turcomans pitched their tents there. When Sir Alex
Burnes travelled the country in 1832, the Khivans were the
of Merv, the nomad population being subject to them. Abou
time the Tekke Turcomans, then living at Orazkala on the Her
were forced to migrate northward in consequence of the pr
from behind of the Persians. The Khivans contested the ad
of the Tekkes, but ultimately, about the year 1856, the latt
came the sovereign power in the country, and have ever
resisted all attempts at reconquest.

MÉRYON, CHARLES (1821–1868). The nam
Méryon is associated with that spirited revival of et
in France which took place in the middle of the
century, say from 1850 to 1865, but it is rather h
individuality of his own achievements, and the streng
his artistic nature, than by the influence he exercised
Méryon best deserves fame. No doubt his work encou
others to employ the same medium of expression, a
great was his own perfection of *technique* that he may
have been made a model; but, after all, the mediu
selected, and in which he excelled, was but the accide
his art; he was driven to it in part by stress of ci
stances, by colour blindness; and, even with colour
ness, his extraordinary certainty of hand and his de
perception of light, aided by his potent imagination, w
have made him a great draughtsman not alone upo
copper.

Charles Méryon was born in Paris in 1821. His f
was an English physician, his mother a French da
It was to his mother's care that Méryon's childhood
confided. She was supplied with money, and she gav
boy passionate affection, if not a wise training. Bu
died when he was still very young, and Méryon in
time entered the French navy, and in the corvette
Rhin" made the voyage round the world. He was al
a draughtsman, for on the coast of New Zealand he
pencil drawings which he was able to employ, years
wards, as studies for etchings of the landscape of
regions. The artistic instinct developed, and, whi
was yet a lieutenant, Méryon left the navy. Finding
he was colour-blind, Méryon determined to devote hi
to etching. He entered the work-room of one Bléry,
whom he learnt something of technical matters, a
whom he always remained grateful. Méryon was b
time poor. It is said that he might have had assis
from his kindred, but he was too proud to ask it.
thus he was reduced to the need of executing for the
of daily bread much work that was wholly mechanica
irksome. Resolutely, though unwillingly, he becam
hack of his art, doing frequently, from the day wh
was first a master of it to the day when insanity dis
him, many dull commissions which paid ill, but paid
than his original works. Among learner's work, do
his own advantage, are to be counted some studies aft

etchers such as Zeeman and Adrian van de Velde. proved himself a surprising copyist, he proceeded our of his own, and began that series of etchings are the greatest embodiments of his greatest con s the series called "Eaux-fortes sur Paris." These executed from 1850 to 1854, are never to be met a set; they were never expressly published a But they none the less constituted in Meryon's mind monious series. For him their likenesses and their ts were alike studied; they had a beginning and an nd their differences were lost in their unity.

les the twenty-two etchings "sur Paris" character low, Méryon did seventy-two etchings of one sort nother, ninety four in all being catalogued in re's *Mérydn and Méryon's Paris*; but these include rks of his apprenticeship and of his decline, adroit r which his best success was in the sinking of his hvidiality, and dull and worthless portraits chiefly otten celebrities. Yet among the seventy two prints his professed series there are at least a dozen that d his fame. Three or four beautiful etchings of o not belong to the series at all. Two or three s, again, are devoted to the illustration of s, a city in which the old wooden houses were ctive to him for their own sakes as were the stone nonuments of Paris. But generally it was when engaged him that he succeeded the most. He have done more work, however, - though he could have done better work, if the material difficulties life had not pressed upon him and shortened his He was a bachelor, unhappy in love, and yet, it is almost as constantly occupied with love as with The depth of his imagination and the surprising which he achieved almost from the beginning in hnicalities of his craft were appreciated only by a ists, critics and connoisseurs, and he could not sell ings, or could sell them only for about 10d. a piece. t that his own original work was of incalculably value than his best copies of his most celebrated ners had not yet impressed itself upon anybody. ointment told upon him, and, frugal as was his way poverty must have told on him. He became subject neinations. Enemies, he said, waited for him at the of the streets; his few friends robbed him or owed at which they would never pay. A very few years he completion of his Paris series, he was lodged in dhouse of Charenton. Its order and care restored r a while to health, and he came out and did a little work, but at bottom he was exhausted. In 1867 rned to his asylum, and died there in 1868. In the years of his life, just before he was placed under con- nt, he was much associated with Bracquemond and Flameng, skilled practitioners of etching, while he nself an undeniable genius,—and the best of the ts we have of him is that one by Bracquemond which the sitter wrote that it represented "the e Méryon with the grotesque visage." And it did.

e are twenty-two pieces in the Eaux fortes sur Paris. Some n are insignificant. That is because ten out of the twenty re destined as headpiece, tailpiece, or running commentary e more important plate. But each has its value, and certain maller pieces throw great light on the aim of the entire set. ne little plate —not a picture at all —is devoted to the record s made by Méryon, the purpose of which is to lament the hte s. The misery and poverty of the town Meryon had to illus s well as its splendour. The art of Méryon is completely ceived when his etchings are spoken of as views of Paris. They n "views," but they are so just so far as is compatible with ing likewise the visions of a poet and the compositions of an It was an epic of Paris that Méryon determined to make, t strongly by his personal sentiment, and affected here and y the occurrences of the moment,—in more than one case, for e, he hurried with particular affection to etch his impression of some old world building which was on the point of destr Nearly every etching in the series is an instance of technica but even the technical skill is exercised most happily in the ings which have the advantage of impressive subjects, and the collector willingly cherishes for their mysterious stage or for their pure beauty. Of these, the Abside de Notre D the general favourite; it is commonly held to be Méryon's piece. Light and shade play wonderfully over the great f the church, seen over the spaces of the river. As a draughts architecture, Meryon was complete, his sympathy with its styles was broad, and his work on its various styles unbro of equal perfection a point in which it is curious to contra with Turner, who, in drawing Gothic, often drew it with appreciation. It is evident that architecture must enter into any representation of a city, however much such repres may be a vision, and however little a chronicle. Besides, th tectural portion even of Meryon's labour is but indirectly i tive, to the imagination he has given freer play in his dealin the figure, whether the people of the street or of the river people who, when he is most frankly or even wildly sym crowd the sky. Generally speaking, his figures are, as draughtsmanship, "landscape painter's figures." They are more with an eye to grace than to correctness. But they "landscape painter's figures" at all when what we are co with is not the method of their representation but the pu their introduction. They are seen then to be in exceptional with the sentiment of the scene. Sometimes, as in the case Morgue, it is they who tell the story of the picture. Someti in the case of La Rue des Mauvais Garçons, with the two women bent together in secret converse, they at least sug And sometimes, as in L'Arche du Pont Notre Dame, it expressive gesture and eager action that give vitality and in to the scene. Dealing perfectly with architecture, and perfe far as concerned his peculiar purpose, with humanity in Méryon was little called upon by the character of his subj deal with Nature. He drew trees but badly, never repre foliage happily, either in detail or in mass. But to render th asperities of the city, it was necessary that he should know portray a certain kind of water river-water, mostly sluggis a certain kind of sky the grey obscured and lower sky that over a world of roof and chimney. This water and this sky is thoroughly master of, he note with observant affectio changes in all lights.

Meryon's excellent draughtmanship, and his keen appreci light, shade, and tone, were, of course, helps to his becoming etcher. But a living authority, himself an eminent etch admiring Meryon thoroughly, has called Meryon by prefe great original engraver, - so little of Meryon's work accord- Haden's view of etching. Meryon was anything but a sketcher; and, if an artist's success in etching is to be gauged by the rapidity with which he records an impression, Mery cess was not great. There can be no doubt that his wo laborious and deliberate, instead of swift and impulsive, and some other virtues of the etcher "selection" and "abstract Mr Hamerton has defined them he shows small trace. genius like Méryon is a law unto himself, or rather in his of his art he makes the laws by which that art and he a judged. He was a great etcher, and by his most elaborate he seemed somehow to come the more completely for his that virtue of unity of impression which, it may well be s oftener belongs to rapid than to deliberate work. In M etchings the hand work never seems to be in arrear of the t As long as the hand-work must continue, the thought and are retained. Meryon knows the secrets of his craft as wel the older masters of it; but he turns them to his own p sel in strength precision, not is h rivalled in delicacy. These qualities, and others more t technical, which it would take too long to insist on here, find in his etchings. But the incommunicable charm of M prints and their lasting fascination are due to the fact that all technical qualities, and as their very source and spri lies the potent imagination of the artist, poetical and vis ing him what to see in his subject, and how to see it.

MESCHERYAKS, or MESCHERS, a people nub eastern Russia. Nestor regarded them as Finn even now part of the Mordvinians (of Finnish call themselves Meschers. Klaproth, on the other supposed they were a mixture of Finn- and Turk-, a Hungarian traveller Reguli discovered that the Ta Meschers of the Obi closely resembled Hungarians. formerly occupied the basin of the Oka (where th Meschersk, now Meschovsk, has maintained their and of the Sura, extending north-east to the Volga. the conquest of the Kazan empire by Russia,

igrated north eastwards to the basins of the Kama
elaya, and thus the Meschers divided into two
s. The western branch became Russified, so that
scheryak of the governments of Penza, Saratoff,
, and Vladimir have adopted the customs, language,
igion of the conquering race; but their ethnogra
characteristics can be easily distinguished in the
population of the governments of Penza and
f. The eastern branch has taken on the customs,
ge, and religion of Bashkir, with whom their fusion
more complete. They can be distinguished from
eighbours only by their more peaceful character.
-Bikir Mescheryak branch was estimated by Rittich
to number 138,000. They make 6 per cent. of
pulation of the government of Ufa, and 22 per
the district of Birsk. The number of the western
ryaks is unknown, and could hardly be estimated on
of their mixture with Russians. It is only in the
ment of Penza that they have maintained their national
s, there they make 3 per cent. of the population.

SCHOVSK, a district town of Russia, in the govern
Kaluga, 15 miles to the south-west of the capital
province. It is an old town supposed to date from
th century, and it is often mentioned in Russian
under the names of Mezetsk, Mezechevsk, or
sk. About the end of the 11th century it was
ed in Lithuania, and it was ceded to the Moscow
principality in 1494. It was often pillaged by Tar
the 16th century, and during the great disturbances
Dali it. inhabitants were killed by the Zaporoghi
ks and the fort was taken by Poles, who returned it
sia only after the treaty of Deulin. The country
Meschovsk is not fertile; but, from its position on
ablished routes to the south, the town has become
e of considerable trade. Its annual fair, which
place on the grounds of the very old Petrovsk
ery, is important to the surrounding districts for
ort sale of horses, grain, hemp, hempseed oil, and
linen, and for the import trade in cottons, woollens,
thern and glass wares, the whole turn-over reaching
2100,000. Population, 7100.

HED (properly Meshhed, *q.v.*, "place of martyr-
dom"), a city of northern Persia, capital of
ân, 472 miles east of Tehran, 201 miles north-west
t 36° 17' 10" N., 59° 35' 29" E., lies on a plain
by the Kashaf rud, a tributary of the Heri rud, and
nded by mud walls 4 miles in circumference, with
itch 10 feet deep at some points, which could be
from the neighbouring reservoir and watercourses.
this enclosure is a strong citadel, with good walls 25
gh, residence of the prince governor of Khorásán.
re five gates, from one of which, the Bala Khiaban,
aban main street runs right through the city, form-
ne boulevard planted with plane and mulberry trees,
h a stream of dirty water running down its whole

In the centre is an open parallelogram 160 yards
encircled by double-tiered cloisters, and pierced on
side by a high arched porch leading directly to
t mosque, whose gilded dome rises above the shrine
amous Imam Riza[1]. The marble tomb of the saint,
which is the most venerated spot in the whole of
and yearly visited by from 80,000 to 100,000 pilgr
surrounded by a silver railing, and approached by a
of inlaid marble steps. Eastwick, the only European
O'Donovan who penetrated as far as the parallel
describes the mosque as large enough to contain
thousand people. It is flanked by two gilded mi

an exquisitely carved capital, built by Shah Abbas.
façade is entirely covered with blue and white ena
tiles. To the mosque are attached as many as two tho
attendants and retainers of all sorts, including no les
five hundred mollahs. Beyond the dome is Gauhar
handsome mosque, surmounted by an immense blue
and also flanked by two minarets. In the main
is a public kitchen supported by the enormous re
of the shrine, where eight hundred devotees are
supplied with food gratuitously. The only other
buildings in the place are some colleges and t
two caravanserais, one of which is of great size. M
does a considerable local and transit trade to the
value of about 600,000 tomans, and its bazaars are
well stocked with silks, velvets, felts, cottons, s
carpets, lacquer work, lambskins, hardware, glass,
and other goods from South Persia, India, Turkesta
Russia. The European trade is now entirely control
Russia, and European manufactured articles are mo
from that country. The chief manufactures are silk
velvet, and checked-cotton fabrics, carpets, shawls,
sword blades, shagreen, and turquois jewellery.
the enclosures are extensive cemeteries far exceedi
local requirements, large numbers of the faithful
brought from all parts of the Shi'a world to be bu
the vicinity of Rizá's shrine under the belief tha
eternal salvation is thereby ensured.

Some 10 miles west of Meshed is a powder factory, fo
under Colonel Dolmage, where powder of excellent quality
duced. The district, although fertile, does not produce su
for the inhabitants, so that much grain has to be import
Kurdistan and Nishápúr. The climate is very severe in wint
much snow, in summer it is less sultry than might be ex
the temperature ranging from 76° F. to 90° or 92° F., and in
hours 94° to 98° F. The population is variously estim
from 15,000 (Connolly) and 60,000 (Fegrier) to 80,000 and 1
(Eastwick). The settled residents, exclusive of pilgrims and
traders, are estimated by O'Donovan at 50,000.

The main caravan routes from Khiva, Bokhara, Samarkan
Herat converge at Meshed, whence lines of traffic radiate to I
for the Atrek valley and the Caspian, to Nishapúr and Bos
Tehran, to Tabas for Isfahan, to Khaf for Sistán and Kirm
thus occupies a position in north-eastern Persia analogous
of Tabriz in the north-west.

MESHED-ALI, *i.e.*, the shrine of the "martyr"
a town of Asiatic Turkey, province of Baghdad, 50
south of Kerbela, close to the ruins of Kufa, and 2
west of the Hindiye branch of the Euphrates, the re
burial place of the caliph Ali.[2] It stands on th
scarp of the Syrian desert, and is enclosed by nearly
brick walls flanked by massive round towers datin
the time of the caliphs. Under the gilded dome
great mosque, which occupies the centre of the town,
shrine of Ali, which is held by the Shi'a as at le
holy as the Kaaba itself. Any Moslem buried
sight of the dome being certain of salvation, large nu
of bodies are yearly sent from all parts for interme
Besides the mosque with its richly decorated façad
only noteworthy building is a good bazaar supplied
Baghdad and Basra. The town itself, which Lady

[1] Rizá (or el-Ridá), the eighth imam of the Shi'a, is the 'Ali ibn
om whom the party of Ali's heirs had such hopes under the
of Mamún (see MOHAMMEDANISM). He died at Tus,
, and was buried by Mamun under the vicinity of that
side the grave of Harun el-Rashid. To the Ali he was
being believed to have been poisoned by the caliph. Ibn Batuta,
ribes both shrines (iii. 77 *sq.*), tells how the pious visitors
me of 'Ali ibn Músa used to spurn with their feet the tomb
[2] In his time a considerable town had been formed around
n under the name of Meshhed el-Rida and ultimately the
n eclipsed the older city of Tus.

[2] Whether the place really contains the grave of Ali w
disputed, and the story given in defence of its claims is de
apocryphal. The dome was built under the Abbasids, and the
place of the caliph unknown or concealed under the Omayya
Haukal, p. 163).

Blunt describes as "an ideal Eastern city, standing in an absolute desert, and bare of all surroundings but its tombs," consists of narrow gloomy streets lined by houses closely packed together. The locality is properly named Najaf, and gives its name to the neighbouring lake, a large depression filled by an eruption of the river, and ranging from 6 to 20 feet in depth. The accumulated treasures of the shrine were carried off by the Wahhábites when they captured this place early in the present century. The population is estimated at 7000, including several Indian Mohammedans under the protection of the British resident at Baghdad.

The aspect of the shrine in the 14th century is described by Ibn Batúta, i. 114 *sq.* A plan of the town and description of its splendour before the Wahhabites pillaged it is given by Niebuhr. See also Ibn Jubair, p. 214; P. Teixeira, *Itin.*, cap. iv.

MESHED HOSEIN, properly Meshhed Hosein. See Kerbela, vol. xiv. p. 18.

MESMER, MESMERISM. See vol. xv. p. 277.

MESOPOTAMIA, the "country between the rivers," is a purely geographical expression, the countries which it comprehends never having formed a self-contained political unity.[1] It was first introduced by the Greeks at or after the time of Alexander, but probably had its origin in the earlier Aramaean name *beth nahrin* (the country between the rivers), to which again corresponds the Biblical *Aram Naharaim*.[2] As early as 700 B.C. "the country of two rivers" is mentioned on the Egyptian monuments under the name Naharina, but no such designation appears in the cuneiform inscriptions (though the territory formed part of the Assyrian as it afterwards did of the Persian empire). The most settled period in the history of Mesopotamia was probably under Persian-Greek rule. Xenophon applies the name Syria to the extremely fertile district which he traversed after having crossed the Euphrates at Thapsacus. The country beyond the Araxes (Chaboras?) he calls Arabia, a desert region in which his army had to suffer great hardships until it reached the "gates of Arabia." Even in later times Mesopotamia was included under the name Assyria, or was reckoned part of Babylonia.

These statements of Xenophon already indicate a demarcation of the territory afterwards called Mesopotamia, as well as its division into two sections. The fertile portion, inhabited by agricultural Aramaeans, stretched from the Euphrates to the Chaboras; the desert portion, the home of wandering tribes, extended to the Tigris. It would be rash, however, to conclude from this that Mesopotamia designated the whole territory between the Euphrates and Tigris; indeed it is possible that *Aram Naharaim*, the Aram of the country of the two rivers, originally meant only the main portion of the fertile country inhabited by Syrians. In this case the two boundary rivers must have been, not the Euphrates and the Tigris, but the Euphrates and the Chaboras. After the final occupation of the country by the Romans (156 A.D.), the political province of Mesopotamia was practically confined to this more limited district. Though in ordinary usage the Euphrates and Tigris are considered as the two rivers which bound Mesopotamia, the one bank of the river cannot be geographically separated from the other, and consequently narrow strips of country on the right bank of the Euphrates and on the left bank of the Tigris must be reckoned to the country "between" the rivers. On the other hand, the country between the sources of the Euphrates and the Tigris has from early times been reckoned not to Mesopotamia but to Armenia. In direction the Masius range forms the proper bound... it is only on rare occasions that theoretical ... extend the name Mesopotamia over the more ... districts, Sophene, &c. [1] Μεσοποταμία, more exactly ἡ μέση τῶν ποταμῶν, scil. χώρα or Συρία.

[2] In the more recent parts of Genesis Padan Aram takes the place of Aram Naharaym. But this perhaps is the name of a smaller district in the neighbourhood of Harran.

s of HARRAN (see vol. xi. p. 154). In the Mongolian Harran fell into decay, and at present it is a mere ruins. A third town of this region is Serug i. 20); in the Greek period it was called Batnæ, but ians retained the name Serug, which is still in use The town lies between Harran and the Euphrates, in to which it gives its name. On the left bank of phrates lay Apamea (the modern Birejik), connected engma on the other side by a bridge, and farther at the mouth of the Bilechas (modern Belik), trading town and fortress Nicephorium, founded mand of Alexander, and completed by Seleucus , in memory of whose victory it was named. he emperor Leo it received the designation Leonto The spot is now known as Rakka (see below). up the fruitful valley of the Belik lay the town of (Chne). Further south lay Circesium (*Chaboras* of , *Phalga* of Isidor), not to be identified, as is usually d, with Carchemish; from the time of Diocletian strongly fortified. The site is at present occupied retched place of the name Karkisiya. Carchemish ly lay near the bridge of Membij, the present el Nejm.

ncient time a highly flou district must have ed along the river Chaboras (Khabûr) to its principal at Ras'am ("Fountain-head," Syr. *Rîsh'aina*, the a of Ptolemy), a town which was for some time called topolis, because after 380 A.D. it was extended and shed by Theodosius. Justinian fortified it. The completely desert country which now stretches along er course of the Khabûr was called in antiquity itis, and corresponds to the Gozan of 2 Kings xvii. zana or Guzanu in the cuneiform inscriptions).

country to the east of the upper Khabur is in many s similar to that which has just been described. As tershed of the Tigris is not far distant, the Masius sends down into Mesopotamia only insignificant s, the most important being the Hermas, the mus of the Greeks. On its banks was situated , the chief city of the district, which commanded eat road at the foot of the mountains leadin h the steppe, which here from the scarcity of water up to the edge of the hills. In the old an empire Nasibina was the seat of one of the four dministrative officials. In the time of the Seleucids e was occupied by the flourishing Greek colony of lia Mygdonia, but the new designation, transferred river and the vicinity of Nisibis from the Mace- district of Mygdonia, afterwards passed out of use. was an important trading city, and played a great n the wars of the Romans against the Persians. red by Lucullus, surrendered by Tigranes, recovered ajan, again abandoned by Hadrian, once more occu- nder Lucius Verus, and strongly fortified by Severus, at length raised to be the capital of the province, mained the frontier fortress of the Romans till in ne of Jovian it was ceded to the Persians. After ss of Nisibis the emperor Anastasius in 507 ed to the north-west the fortress of Dara or Daras nodern Dára), also called Anastasiopolis, which from gn of Justinian, who increased its strength, remained ime the residence of the *dux Mesopotamiæ*. Besides strongholds, many fortified posts were established Byzantine empire in this district. Antoninopolis be mentioned as an important town, this was ied by Constantine under the name of Constantia, s left its ruins near Tela between Harran and Nisibis. n too was a fortress of a similar kind, and the town gara, at the southern foot of the mountain of the name, was an advanced post of the Roman power.

The south or steppe portion of Mesopotamia was early times the roaming-ground of Arabic tribes Xenophon gives the name of Arabia to the district left bank of the Euphrates to the west of the Kh and elsewhere it is frequently stated that the interio distance from the rivers was a steppe inhabited by A Scenitæ (Tent Arabs). Along the bank of the two rivers ran a belt of cultivated country, and the islands of the Euphrates were also occupied by a s population. On the Euphrates, beginning towards north, we must mention first Zaitah or Zautha, south of Circesium; next Corsothe, at the mouth of the Mas then Anatho or Anathan, the modern Ana; and f Is (Hit). On the Tigris the point of most importa Carrhæ (*Karrai* of the *Anabasis*), south from the mou the Great Zab near the present Kal'at Sherkát; an far distant towards the interior was Atræ or Hatra called Hatra, the chief town of the Arab tribe of the A It was besieged without success by Trajan and Sev by the 4th century it was already destroyed; bu nteresting ruins, which can scarcely be visited owi the plundering habits of the Bedouins, still bear the of El Hadhr. They lie in the heart of the steppe were formerly well supplied with water.

hese districts came in 610 A.D., or perhaps a earlier, into the power of the Arabs, who named Jezíra (island) or Jeziret Akúr,[1] and divided them acc to tribes into three portions, the land of Beki, of B and of Modhar. The district of Modhar ran alon side of the Euphrates, and its chief towns were Orf Rakka, the district of Rebí'a comprised the pla Mosul as far as the country on the Khábur (chief Mosul and Nisibis), and the district of Bekr (Diyár the more mountainous country to the west of the Tigris (chief town Amid or Diarbekr). In genera Arabs consider a part of the mountain territories wh between the two rivers to belong to Jezíra, as is bes from the following notice given by Abulfeda:—

"El-Jezíra is the land between the Tigris and the Euphrat many places on the other side of the Euphrates, which p belong to Syria, are also included, as well places and ev tricts on the east side of the Tigris. The exact boundary li runs from Malatia by Sumeisát, Kal'at er-Rúm (Rum Kala maps), and Bire (Birejik) to the point opposite Membij, an by Balis, Er Rakka, Karkísiyá, Er-Rahaba (on right banl Hit to Anbar. Here the Euphrates ceases to form the bou which runs across to the Tigris in the direction of Teki ascends the Tigris as far as Es-Sinn (Senna) to El-Hadit Mosul, thence to Jeziret ibn 'Omar, then to Diarbekr, and so Malatia"

From the Arabic geographers and travellers we ga impression that a great part of Mesopotamia, with t ception of the southern steppe of course, must at tha have been in a very flourishing condition; the neighbou of Nisibis especially is celebrated as a very paradis fact it is only since the Turkish conquest of the c under Sultan Selim in 1515 that it has turned into a and gradually lost its fertility. As the nomadic have continually extended their encroachments, agric has been forced to withdraw into the mountains; a is especially true of the western portions of Mesopo the district of Rás-'ain, and the plain of Harran and where huge mounds give evidence that the whole c was once covered with towns and villa Und Turks El-Jezira does not form a political unity, b longs to different pashaliks.

From this brief survey it appears that Mesopotam Syria, constitutes an intermediate territory betwe great eastern and western monarchies,—Syria in

[1] Philostratus (*c.* 200 A.D.) already reports that the Arab Mesopotamia *νῆσος*.

to the west, and Mesopotamia to the east. In
e of its position it frequently formed both the object
the scene of contest between the armies of those
y monarchies, and it is wonderful how a country so
devastated almost always recovered. The roads, it is
which traversed the territory were not mere military
ays, but the main routes of traffic for Central Asia,
ern Asia, and Europe. It is only in modern times,
since these lines of commercial intercourse have
d to be followed, that the general condition of things
en so entirely altered.

e number of roads which in ancient times traversed
ountry was very considerable; the Euphrates formed
barrier but a bond between the nations on either
at many places there were at least boat bridges
na) across. One of the most important of the
t crossing places must be sought, where in fact it still
at Birejik, the ancient Apamea-Zeugma. From this
a great road led across to Edessa (Orfa); there it
d into two branches, the northern going by Amid
ekr) and the other by Mardin and Nisibis to Mosul
veh). In quite recent times, in order to avoid the
route across the desert and through the midst of the
ins, the post-road makes a great circuit from Nisibis
ziret ibn 'Omar to Mosul. A second route crossed
uphrates somewhat more to the south, and joined the
via Harran and Rhesaena. The principal crossing
earlier times (Xenophon) was at Thapsacus, almost
te Rakka; and it will be remembered also how
tant a part Thapsacus (Tiphsah) plays in the Old
nent. Sometimes a route along the Euphrates to
ona was followed, as is still frequently done by
ns at the present day; but even in ancient times
ourse was attended by more or less difficulty, the
y being occupied by the chiefs of independent
tribes, with whom the travellers had to come to

ancient condition of things must consequently be
ered as essentially analogous to that of the present
the central districts away from the rivers were occu-
t certain seasons, according as they yielded pasture,
nadic cattle grazing tribes, the physical character of
untry being then and now the same on the whole as
f the Syrian desert, which belongs not to Syria
roperly to Arabia. On the banks of the rivers were
l half-nomadic Arab tribes,- tribes, that is, which
more or less on the way to the agricultural stage, or
having become altogether agricultural, had never
s, owing to frequent intercourse with the Bedouins,
ttle of their original character, and even maintained
ndependence. The same movement takes place over
ver again. Arab tribes migrating from Arabia, that
gentium, gradually settle down wherever circum
s prove favourable, and by this very change in their
of life make their first step towards civilization. In
way a continual stream of Arabs has flowed into
vilized countries of Mesopotamia. On the Assyrian
ments are figures of Arabs riding on camels; evidently
ssyrians had carried on war against the Bedouins
l in their territory. At an early period the Tai Arabs
he neighbours of the Aramaeans, and consequently all
bear in Syriac the name of Tayóyé. The district
n Mosul and Nisibis received the name Béth 'Arbáyé
ts being occupied by Arabs. These Tai Arabs, whose
al home was Central Arabia, are still settled partly
Nisibis and partly east of Mosul; but they have to
extent lost their old noble Bedouin manners. The
ring Arab tribe which at the present time is
ant in Mesopotamia is the Shammar; they have
back the Aneze, the most powerful tribe of the
Syrian desert. It is only two or three generatio
that the Shammar came from Nejd; but they have
broken up into two great parties. The head of
division is Ferhán, who has more or less comple
mitted to the Turks, and has consequently obtai
title of pasha; to him adhere the Shammar tribes
Mosul and Baghdad, and those also to the east of the
The head of the tribes who roam over the greater

contribution by exacting Khuwwe, "brother mone
portion of grain. The Shammar live in almost pe
feud with their relations to the east, and especially
Aneze on the Syrian bank of the Euphrates, the s
Shammiye. Many other Bedouin tribes might
mentioned; but it may be enough to name the De
the Euphrates as an example of a tribe just in pro
becoming agricultural. In the northern parts of
tamia there are a number of tribes of mingled Kur
Arabs which have to a greater or less degree aba
their tents for fixed habitations and the tillage
ground; such are the Beruziye near Orfa, the
between Orfa and Mardin, and the Kiljye nearer
and also in the neighbourhood of Mosul. It is ex
hard to obtain trustworthy statistical information
the number of the Bedouins, the Shammar may
total strength of some 3500 tents. In the difficult
which it has to carry on with those independent
tribes, the Turkish Government acts in general
principle *divide et impera*.

The Kurdish element only appears sporadically
rue Mesopotamian plain; but the Yezidis, who
population of the Sinjar range, may be referred
stock. He who encounters the uncanny figure of
these people will hardly be able to restrain a slight
especially if he remembers the graphic description
Yezidi robbers in Morier's *Ayesha*. Of the old
peasantry there are no longer any important remain
plain, the Aramaeans having withdrawn farther i
Kurdish highlands, where, in spite of their wild
neighbours, they are more secure from exactions
kind. The plain of the northern country of the two
was at one time richly cultivated, and owed its pr
to this industrious people, who formerly played
guished a part as a connecting link between the
and the Roman empire and afterwards between the
and the Arabian world, and whose highest cultu
developed in this very region. Quite otherwise is
In the plain there are almost no remains of the
Aramaean tongue. Apart from the scattered areas i
Kurdish prevails, the ordinary language is a vulgar
dialect; but both Kurdish and Aramaean (Syria
exercised an influence on the speech of the Arab
Finally it must be mentioned that certain Turcoman
roam about the Mesopotamian territory.

In climate and in the character of its soil, as well as in
graphic history, Mesopotamia holds an intermediate po
this aspect also we must maintain the division into two qui
zones. The southern half consists mainly of grey, cha
covered with selenite, and gypsum everywhere makes its ap
a little below the surface. Bitumen is not infrequent and
there it rises in petroleum wells. In the solid strata of gyp
marl the rivers have carved out valleys, from a quarter to ha
broad and from 40 to 50 or even 100 feet deep, which with the
soil contrast with the barren surface of the more elevate
(*chól*). Especially below Balis there are marl-hills capp
gypsum, and alluvial plains so called *hauran* of considerabl

n formed The banks of the rivers are there lined with a
t growth of tamarisk Occasional swamps and marl
pecul ; and the marl shows a more or less marked efflore-
salt In this part of the country frost is rare even in
n summer the heat is of extraordinary intensity, and
he whole season, from May to the close of October it is but
modified by the night dews During the sand storms
equently blow from the West Arabian desert, the tempera
rise to 50° C (122° Fahr), and this same excess of heat will
vail through several degrees of latitude in the whole valley of
hrates and Tigris from the Persian Gulf to the foot of the
ns For, considering the strong radiation which takes
er what is now the uniform surface of the Mesopotamian
its almost complete absence of evaporation, there is
to hinder the warm zone extending in summer to the
ll of the country In winter, on the other hand, this latter
s quite a different climate From the cold coasts of the
n mean the cold increases from west to east In the spring
ourse consequently the winter cold extends far to the south,
moisture of the snow-covered ridges spreads far into the
ancan plain Snow and ice are thus not unfrequent in the
part of the plain, and the temperature may fall as low as
(4° Fahr) especially if the cold north winds are blowing
Land is soon to the east cut off from the influence of the mild an
Mediterranean by the coast ranges For this reason the
ter is of a less southern character than that of the Mediter
ean in the same latitude In the spring the green
ation dies out of existence In this way the northern district
peculiar contrast, and is a connecting link

In conclusion it is necessary in supplement to the artic
to say something of the district of Babylonia, often (though
included under the name Mesopotamia. Here we have to
a fundamentally different region, for it consists in the
alluvial formations, a few scattered reaches of sand only
then appearing in the level depression not filled up by the a
The mass of solid matter which the rivers bring down and
is very considerable; it has been ascertained that the m
proportion for the Euphrates in the month of January is
at other times $\frac{1}{300}$; for the Tigris the maximum is
regard the physical character of the alluvia, in the most n
portion the soil is pebbly, the pebbles consisting almost
variously coloured flints and occasional small fragments of
This is succeeded by a continuous formation of clayey soil
argillaceous and argillo-calcareous, but covered with mo
sand, or the more tenacious clay of frequent inundations.

In general, the northern plains of the interior have
but well defined southerly inclination with local depression
territory undulates in the central districts, and then sinks a
mere marshes and lakes. The clay, of a deep blue colour,
with marine shells, and shows a strong efflorescence of na
sea-salt, the latter derived from the decomposition of v
matter When the soil is parched up the appearance
mirage (serab) is very common As extensive munda
spring are caused by both the rivers, especially the Tigr
alterations must have taken place in this part of the
in the course of thousands of years. It has been asserted
former times the alluvial area at the mouth of the river
one mile in the space of thirty years; and from this it
assumed that about the 6th century B.C. the Persian G
have stretched from 15 to 55 miles farther inland than at
The actual rate of increase at the present time is about 72
annum. For this reason we cannot decide much in regar
former physical configuration of southern Babylonia, but it i
certain that the Euphrates and the Tigris reached the sea
pendent rivers. Ritter estimates that in the time of Alexa
Great the embouchures were still separated by a good day's j
and, though they cannot now be traced, great alteratio
probably taken place in the upper portions of the rivers a
in the country near the mouths. Assyriologists tell us th
than thirty-five canals are known by name from the Bab
period; but it is extremely difficult, or rather it has proved
impossible, to identify them either with those actually ex
with those mentioned in classical authors, in the Bab
Talmud, or in Arabian writers. To the west of the Euphr
to be found the Pallacopas channel, and we still have the
channel in the same quarter. The country between the rive
particularly was traversed by such secondary branches. Be

Euphrates we must mention the Saklawiye channel (Nahr Nahr Melik, the Nahr Zemberániye, and especially the -Nil, structed by the famous Omayyad

Eastwards from the Tigris strikes the great Nahrawan ; and right through the country of the two rivers runs tt el Hai from Kut-el-'Amára, almost due south to the ís, parallel with the Shatt-el-Kehi Many of these have ted up; from those, however, which are still maintained derived a considerable revenue, and by the restoration y of the old channels, traces of which are met with at ep, the country might be again raised to that condition civilization which it enjoyed not only in antiquity but ven in the time of the later caliphs. The classical writers mmons in their admiration of this country, and it is at tain that nowhere else in the whole world was the principle pplication of canals to the exigencies of agriculture worked successfully. The most luxuriant vegetation was diffused whole country; and three crops were obtainable in the t is this alone which makes it intelligible how this region most remote antiquity attained a high civilization, and for s played, it may be said, one of the principal parts in the of the world In the matter of civilization, indeed, no of the ancient world was its equal, a multitude of great ace flourished within its borders. Even the Arabic writers mmons in regard to the extremely favourable influence he character of the country exercised on the intellectual , spirit, and capacity of its inhabitants. We need not the question recently started as to whether the Biblical of Eden is to be sought in this locality, two canals of the tes and Tigris being identified with the Gihon and Pison of ; but it is certain at least that this lower country of the rs might well pass in antiquity for the *ne plus ultra* of ion, and exercised the most powerful political and int influence on the surrounding regions. The question often s to whether the Semites were derived this district o be left unto Bible we know that name of the district was Shinar, though this has not been discovered in the cuneiform inscriptions. The name applied in the Bible to its oldest non-Semitic inhabitants. thern half of the country was called Akkad, the southern But it must not be forgotten that the rivers never formed aphic and political boundaries, and thus Sumer extended ast of the Persian Gulf and Akkad as far as the Lower Zab, ern affluent of the Tigris

whole country may be termed *mat Kaldu*, the country of ldeans (Hebr., *eres Kasdim*); originally Kalda is said to signated central Babylonia. Of still later date is the name from the capital, the country of Babel (*eres Babel*), as an nt of which *mat Bábilu* appears in the cuneiform inscriptions Darius lists *Babirus*. From this was developed the Greek tion Babylonia, Βαβυλωνία (as early as Xenophon). That this was densely peopled may be gathered from the fact that about eighty-nine fortified towns and eight hundred and twenty places in the Chaldean country were captured during one expedition. Of separate districts of the country we may Kardumiash, the district in the vicinity and especially to the f Babylon; and southward by the coast the important of Bít Yakín, governed by kings of its own. At a later date on the coast and at the mouth of the Pallacopas canal the e town of Teredon, which is also mentioned by the classical Besides Babylon and Borsippa, the larger cities were the ity of Sippar (Sefarvayim, 2 Kings xvii. 24, 31) and Akkad eft bank of the Euphrates on the present Nahr 'Isa; Erech, arka, on the left bank of the Euphrates, Ur on the Pallacopas not far from the place where the Shatt el Hai falls into the Nippur, *i.e.*, Tell Niffer; Kutha (2 Kings xvii. 24). Kalneh . 10°, in the north, Opis at the junction of the Adhem ss) with the Tigris Huge mounds give evidence of the of these cities. A number of the canals were navigable, the same time, when the bridges were destroyed, they defensive moats against the incursion of enemies from the And the same purpose was served by the great wall (after he Median Wall of the Greeks) which ran across the country ver to river between the points of their nearest approach.

ng the period of Greek domination a Greek city Seleneia, afterwards attained great prosperity, was founded by s I. in an extremely favourable situation on the right bank Tigris. In the south of the country, too, there was a Greek town first called Alexandria on the Tigris and afterwards ia. After the conquest of Babylonia by the Parthians) a small Arabian kingdom grew up in those parts called ene or Mesene, after the town of Charax or Meisan. It was Parthian and for a time under Roman supremacy. The city gesia, founded by Vologeses to the south-west of Babylon, lais, in the neighbourhood of the later Kúfa, was one of the s of the Parthian power. In the time of the Sasanids, too, l as in that of the Parthians, the country of the lower Euphrates and Tigris played a leading part, it formed in f main centre of the Persian kingdom. The city of Cte founded by the Greeks on the east side of the Tigris c Seleucia, was the winter residence of the Parthian kings, a imperial capital of the Sasanids. Under the name of (The Cities) it continued to flourish till the rise of Baghdad 9th century. The neighbourhood of Ctesiphon was called time of the Sasanids Surestan, a translation of the Aramaic nation Beth-Arámaye, "country of the Syrians," for the l mainly occupied by Aramaeans. By a notable substitut Arabs afterwards gave the name Nabat *i.e.*, Nabataeans, t Aramaean peasantry, who, it may be added, were already fo the e parts at the time of the Babylonian empire.

On the west side of the Tigris the Arab kingdom of Hira the bulwark of the Sasanid power. At the result mainly battle of Kadisiya (east of Hira) in 635 A.D., the whole wealthy country fell into the hands of the Moslems, and it stituted the centre of their power, especially when the Ab with true political insight, transferred thither the capital npire and founded Baghdad. The chief cities of the older period were Kuta on the neighbourhood of the earlier Hi south of an ient Babylon) and Basra (or Bassorah, *q.v.*) neighbourhood of the earlier Mesan. After these two c country was divided into the Sawad, "rich arable distri Basra and that of Kufa. Sawad was also employed as a n the whole country al me less identical with this 'Irak still means. Sometimes also the term el 'Irak is employed but at a later date the country is distin as 'Irak 'Arabi (Arabian Irak) from the Persian 'Irák Ajem erst the ancient Media. The Arabian geographer Yakút ma distinction that the country called Sawad reaches farther north (viz., to the district of the Upper Zab.

Abulfeda gives the boundaries of Irak as ows "In t of the country lie El-Jezira and the desert, in the south the the Persian Gulf, and Khuzistan in the east the mountain Holwan (the principal pass through the range). The the boundary runs again towards Mesop Thus the gr breadth of 'Irak is in the north, and it extremity is formed by the island Abbadan in the Shatt (the united Euphrates and Tigris) to the south of Basra." what has been said it appears that 'Irak extended far bey country between Euphrates and Ti Abulfeda says elsew 'Irak lies on the Tigris as Egypt on Nile; for according of the country consequently lies between 30° and 34° 30' N. lat. and betw and 48° 30' E. long., of its area it is impossible to fo under such varying conditi ne details see BAGH

From the union of the rivers upwards, in the case of the Eu as far as 26° N. lat. (above Rakka), in that of the Tigris to lat., the valleys are known as el-Ghór, the depression, in oppo the more elevated desert plateau. It has been surmised that name is to be recognized the Dúra of the Old Testament (Dan. iii. 1).

Very fr the ancient ition of the country has b served; and there are now but few remains of ancient bu scarcity of stone having all alo d to the use of brick has played its part. It is only by xpenditu sums, far beyond the financial capacity of the Turkish nent, that the ancient canals could be restored and the formed by them drained. The whole land falls into two portions, an extensive dry steppe with at any rate a desert climate, and an unhealthy region of swamps. Th good deal more agriculture along the Euphrates than al Tigris, but swamps, with almost impenetrable reed thick pered of a kind of *Typha*, are at the same time much mo ive. The slightly more elevated districts are the special of the date palm, which by itself forms dense groves borde banks particularly on the lower Euphrates, for a distance days' journey. This part of the country consequently has what monotonous but in own way imposing aspect riant vegetation of water-plants is to be found in the which are the haunt of numerous wild beasts, wild swin different kinds of aquatic animals and birds. The swa inhabited by a wild race of men, dark of hue, with many amongst them. They live in reed huts, and cultivate they weave straw mats. In the main they keep pretty fre the Turkish Government and of the semi-Bedouins and Be 'Irak. The Khazael especially who dwell to the south of Babylon often give the Government trouble, through their for independence. Less turbulent are the Bedouins in the of the country the Zobeid, the Aturi, and the Abu Muhamm on the other hand the Beni Lam (7500 tents strong, who oc great tract of country east of the Tigris to the south of B have often been a source of great annoyance to the pashas city. A still more difficult task is the management of th mar, who come and pitch their tents to the south-east of B and also the Muntefik on the southern Euphrates put the w

tive and diplomatic skill of the Turkish officials to the test. kish influence has here made at one time great advance nother lost all the ground it had gained, the rich and sheikhs of the Muntefiteh sometimes become for a season er the whole of Southern 'Irák and even over the town of The present writer once visited the great sheikh Nasir in near Súk esh-Shuyúkh; and he received the impression g to do with a very remarkable and astute personage old Syrian population of 'Irak has almost entirely dis- d; the few remnants left are distinguished by a special in regard to which see the article MANDÆANS. Ethno- lly the country is subject to a double influence. On the d the connexion with Nejd the central plateau of Arabia, s uninterrupted; the emigration from that region being directed towards 'Irak and decreases. In Baghdad en, the dozens from Central Arabia have a quarter of their own. he earnings obtained in the rich districts the emigrants o their homes. But quite as strong at least is the influ Persia. Persian customs are in fashion; in Baghdad an important Persian quarter, and Kerbela and Meshed the west of the Euphrates may be considered regular "enclaves." In these places are buried the son-in-law of med, the caliph Ali and his son Hosein (in Kerbela), the nts of the Shiite sect, and their tombs are not only shrines mage to the living, but the dead are brought by countless from Persia to be buried in ground which they have made The neighbourhood of Kerbela reeks with the odour of and from the midst of them pestilence has often begun its The whole of Irak the Shiites have many ad- for example, the Khazel already mentioned. Persian e prevail on the Arab population of 'Irak, and the inter g of the races can still be very clearly traced; in this dis- ct of the Turkish empire a more international tone prevails any other district. And, however small when compared rmer times the commercial and intellectual intercourse of nations in these regions may be at the present day, the observer must note that such intercourse does still though within restricted limits. No trace, indeed, is to be d that rich intellectual development which was produced in the caliphs through the reciprocal action of Persian dic elements. Still the quickwittedness of the inhabitants makes a decided impression on the traveller passing through Turkey; and one might venture to prophesy that the might to some extent recover its former position in the especially if English influence from India were more widely d, and should lead to the construction of a railway. The hich passes through 'Irak is even now not unimportant; ample are exported in saleable numbers from n 'Irák to India. But it might be very much improved, as ntry, it is said, could support five hundred times as many ants as it actually contains. There is also a considerable of dates, a fruit which forms the chief sustenance of a great of the inhabitants; and the breeding of cattle (especially ep) is extensively carried on. Only a few steamboats as yet e the Euphrates river. Communication by water is carried n rafts or the most primitive craft. Goods are transported so-called "terradies," moderately big high built vessels, also venture out into the Persian Gulf as far as Kuwet. ers are conveyed, especially on the Euphrates, in the , a very long and narrow boat, mostly pushed along the ank with poles. The Mesopotamian "kelleks" rafts laid kins to, later come down as far as Baghdad, where round made of plaited reeds pitched with asphalt are in use. At on the other hand, we see the "belem," boats of a large ving the appearance of being hollowed out of tree trunks, ally not so constructed. Throughout 'Irák in general influence is partially at work; in the hot summer months, tance, when the native lives in underground apartments), the Indian punkah is used in the houses of the rich. A language, the local Arabic dialect has evidently been on the one hand by Persian, on the other by the Bedouin t speech.

SSENE, the chief city of Messenia, founded, under spices of Epaminondas, as a bulwark against the ns. After the battle of Leuctra that general sent the exiled Messenians, in Africa, Sicily, or Italy, ited them to return to the land of their fathers. came with eagerness, and in 369 B.C. the city was y the combined army of Thebans under Epaminondas rgives under Epitelès, assisted by the Messenians themselves. The site was chosen in conformity v vision which appeared to Epaminondas, and the were raised to the sound of flutes playing the a Sacadas and Pronomus. The citadel was erect the summit of Mount Ithome, and the city on its sou slope and in the adjoining valley. City and citade enclosed by a wall 47 stadia in length. Near the of the city was the agora, with a famous spring Arsinoe, and various temples and statues, among the an iron statue of Epaminondas. The Hierothysio tained many statues of gods and heroes, among t bronze statue of Epaminondas. In the gymnasium statues of Hermes, Hercules, and Theseus by Eg artists. In the stadium was a bronze statue of the hero Aristomenes, who had a sepulchral monumen where in the city. On the summit of the citadel famous spring called Clepsydra, and near it a tem Zeus Ithomatas, with a statue by the famous Argive Ageladas, executed originally for the Messenian who settled in Naupactus (see MESSENIA). It v honour of this statue that the festival of the Ithoma performed.

The situation of Messene is one of the finest and romantic in the world. The view of Mount Ithome its level summit and its ancient and mediæval ru one issues from the Langadha Pass in the Ta mountains, is beautiful beyond description. An view from the summit of the mountain itself, which steep and rugged, to the height of 2631 feet, a crowned by the ruins of fortifications of Cyclopean manship, is enchanting, hardly equalled by any o Greece. Near the middle of the ruins of the low stands a wretched village named Mavrommati (Black so called from the Turkish name of the spring A which still flows as plentifully as in the old days. ruins are the most imposing in Greece, and furni finest existing specimen of Hellenic military archit Almost the entire circuit of the ancient walls can be and in some places they are standing to their full They are built of large hewn stones laid in beau regular layers without mortar, and are surmoun towers, of which there seem to have been original thirty. Seven of these are still in a good state of vation, and bear testimony to the thoroughness of th enterprise undertaken by Epaminondas. Two gat still be distinguished, one on the slope of Mount I the other (the northern or Megalopolis gate) on the side. The latter is a dipylon or double gate, openi a circular enclosure 62 feet in diameter. The w this enclosure are built with extreme care, and th stone of the inner portal, which has been partly from its place, reminds one of the lintel of the s treasury of Atreus at Mycenæ. It is 18 ft. 8 in. × in. × 2 ft. 10 in. Within the town several ancien can still be distinguished—the stadium, the theatr several temples.

MESSENIA (in Homer Messene), a state of Gree the most westerly of the three peninsulas of the P nesus. Its area is a little over 1160 square miles. separated from Elis and Arcadia on the north by th Neda and the Nonian mountains, and from Laconia east by the lofty range of Taygetus. The other si washed by the sea, which indents its shores with fou or bays. Messenia, Phœnicus, Pylus, and Cyparissu its south west corner are the Œmussæ Islands, an site the bay of Pylus (Navarino) the famous Sph The interior is divided by mountain chains into plains, watered by rivers, the chief of which is the P (with its tributaries Leucasia, Charadrus, Amphit Aris), falling into the Messenian Gulf. The great

river is divided, near Mount Ithome, into two parts, the plain or basin of Stenyclarus on the and the plain of Macaria, so called from its extreme , on the south. The climate is delightful.

earliest inhabitants of Messenia were Leleges, whose was at Andania. After these came Ætolians, whose entre was at Pylus. After the Dorian conquest the was divided by Cresphontes into five parts, whose ities were respectively Stenyclarus, Pylus, Rhion, , and Mesola. The towns of Messenia were not ns. Homer mentions Pylus (the seat of the ian Neleids), Amphigeneia (possibly the same as ia), Dorion, Æpeia (possibly Methone), Œchalia, Antheia (probably the later Thuria), Pedasus, and later Abia). Other important towns were Asine, Limnæ, Carnasium, Cyparissia, and, finally, e.

history of Messenia before the Dorian invasion little is except a few fables related by Pausanias. Two generations Trojan war, the country was invaded by the Dorians, who the Neleids and conferred the sovereignty upon Cresphontes, ns to have been a popular king. Perhaps for this reason put to death by the chiefs along with all his sons except Æpytus was restored to the throne by the Arcadians. ngeance for his father's death, and became very popular. lasted through several generations. We know little of the ent history of Messenia until the date of the Messenian wars, gainst Sparta. The ostensible and immediate causes of these variously assigned: but the true cause was the cupidity of Our chief trustworthy authority for the history of them l elegiac poet Tyrtæus; but so little is known about them is a matter of doubt in which of them the great hero enes won his fame. The date of the first was from 743 to the second from 685 to 668 or, according to others, from 31 B.C. Ithome was the centre of action in the first, Eira econd. The result of these wars was the complete subjugaMessenia to Sparta. Its territory was parcelled out among , and its towns handed over to Penæci and Helots. Many habitants took refuge in Arcadia, but still more in Italy ly. A very large number settled in Rhegium, whose chiefs y generations were of Messenian stock. About 200,000 behind in bondage. After the second war a large number nians settled on the Sicilian coast at Zancle, to which they ntly gave the name Messana (see MESSINA). In 464 B.C. senian Helots, taking advantage of an earthquake at Sparta, and, though they were finally compelled to surrender in y did so only on condition of being allowed to retire to ns on the Corinthian Gulf. This city had been offered them idence by the Athenians, ever glad to favour the foes of Here the Messenians remained for sixty years, until the he battle of Ægospotami deprived them of the protection of enians. They were then driven out, and had to find homes allenia and Zacynthus, or among their kinsmen in Rhegium sana. Some even went to Africa, and took up their abode peride or Hesperidæ, afterwards called Berenice. Things l in this condition until 369 B.C., when Epaminondas, roken the power of Sparta, rent from her Messenia, and, g from all quarters the descendants of the exiled inhabitelped them to found the city of MESSENE (*q.v.*). Sparta ve up her claim to Messenia, and made many attempts to r it, but without success. The Messenians maintained dependence until 146 B.C., when, with the Achæans, they duced under the power of Rome. From that time they fall background of history. In the Middle Ages the country, rest of the Peloponnesus, was largely overrun by Slavic s is shown by the numerous Slavic local names occurring in the establishment of Greece as a kingdom, Messenia was ted into a province, with a governor or nomarch residing at ta (officially Kalamai), the ancient Pharæ. The country, beautiful and fertile, is still in a deplorably backward conand the population is sparse and semi barbarous. Agriculguishes, and the roads and bridges are few and bad. More violence occur in Messenia than in any other part of Greece. e exception of Kalamata, it contains no town of importance. o, on the Gulf of Pylus, was the scene of the destruction of kish fleet in 1827.

SSIAH (Dan. x. 25, 26), MESSIAS (John i. 41;), are transcriptions (the first form modified by ee to the etymology) of the Greek Μεσσίας s, Μεσείας), which in turn represents the Aramaic (*mĕshîḥâ*), answering to the Hebrew מָשִׁיחַ, "the anointed."[1] The Hebrew word with the article occurs in the Old Testament only in the phrase anointed priest" (Lev. iv. 3, 5, 16; vi. 22 [15]), "Jehovah's anointed" is a common title of the kin Israel, applied in the historical books to Saul and D in Lam. iv. 20 to Zedekiah, and in Isa. xlv. 1 exte to Cyrus. In the Psalms corresponding phrases (My, His anointed)[2] occur nine times, to which may be a the lyrical passages 1 Sam. ii. 10, Hab. iii. 13. I intention of the writers of these hymns there can gene be no doubt that it refers to the king then on the th or, in hymns of more general and timeless characte the Davidic king as such (without personal referen one king);[3] but in the Psalms the ideal aspect o kingship, its religious importance as the expression organ of Jehovah's sovereignty, is prominent. Whe Psalter became a liturgical book the historical kin had gone by, and the idea alone remained, no longer a interpretation of a present political fact, but as pa Israel's religious inheritance. It was impossible, how to think that a true idea had become obsolete n because it found no expression on earth for the time b Israel looked again for an anointed king to whom words of the sacred hymns should apply with a force realized in the imperfect kingship of the past. Th psalms, especially such psalms as the second, were sarily viewed as prophetic; and meantime, in accor with the common Hebrew representation of ideal thin existing in heaven, the true king remains hidden with The steps by which this result was reached must, hov be considered in detail.

The hope of the advent of an ideal king was onl feature of that larger hope of the salvation of Israel fr evils, the realization of perfect reconciliation with Jeh and the felicity of the righteous in Him, in a new or things free from the assaults of hostile nations an troubling of the wicked within the Hebrew comm which was constantly held forth by all the prophets, the time when the great seers of the 8th century B.C proclaimed that the true conception of Jehovah's re to His people was altogether different from wha realized, or even aimed at, by the recognized civ religious leaders of the two Hebrew kingdoms, and t could become a practical reality only through a deliverance following a sifting judgment of the terrible kind. The idea of a judgment so severe render possible an entire breach with the guilty pas of a subsequent complete realization of Jehovah's kin in a regenerate nation, is common to all the prophet is expressed in a great variety of forms and images ditioned by the present situation and needs of Israel time when each prophet spoke. As a rule the pr directly connect the final restoration with the remo the sins of their own age, and with the accomplishm such a work of judgment as lies within their own ho to Isaiah the last troubles are those of Assyrian inv to Jeremiah the restoration follows on the exile to Ba Daniel connects the future glory with the overthrow Greek monarchy. The details of the prophetic pi show a corresponding variation; but all agree in givi central place to the realization of a real effective kin of Jehovah; in fact the conception of the religious s

[1] The transcription is as in Θεσσαύρ, Θεσσίρ for נִשְׁר, *Onom* ed. Lag., pp. 217, 281, Βασ. β ii. 3. For the termination חא, see Lagarde, *Psalt. Memphit.*, p. VII.

[2] The plural is found in Psalm cv. 15, of the patriarchs as ated persons.

[3] In Ps. lxxxiv. 9 [10] it is disputed whether the anointed the king, the priest, or the nation as a whole. The second perhaps the best.

nation of Israel, with a national organization under
h as king, is common to the whole Old Testament,
rms the bond that connects prophecy proper with
called Messianic psalms and similar passages which
gians call typical, *e.g.*, with such passages as speak
religious relations of the Hebrew commonwealth,
ligious meaning of national institutions, and so
arily contain ideal elements reaching beyond the
al present. All such passages are frequently called
nic; but the term is more properly reserved as
cific designation of one particular branch of the
w hope of salvation, which becoming prominent in
nomeal Judaism, used the name of the Messiah as
nical term (which it never is in the Old Testament),
ercised a great influence on New Testament thought,
term "the Christ" (ὁ Χριστός) being itself nothing
than the translation of "the Messiah."

he period of the Hebrew monarchy the thought that
h is the divine king of Israel was associated with the
tion that the human king reigns by right only if he
by commission or "unction" from Him. Such was
ory of the kingship in Ephraim as well as in Judah
xxxiii.; 2 Kings ix. 6), till in the decadence of the
n state Amos (ix. 11) foretold the redintegration of
vidic kingdom, and Hosea (iii. 5; viii. 4) expressly
ted as similar prediction with the condemnation of the
p of Ephraim as illegitimate. So the great Judæan
t of the 8th century connect the salvation of Israel
e rise of a Davidic king, full of Jehovah's Spirit, in
all the energies of Jehovah's transcendental kingship
t were incarnate (Isa. ix. 6 *sq.*; xi. 1 *sq.*; Micah v.).
conception, however, is not one of the constant
s of prophecy, indeed the later prophecies of Isaiah
different hope, looking for the decisive interposition
hovah in the crisis of history without the instru-
lity of a kingly deliverer. Jeremiah again speaks
future David or righteous sprout of David's stem
5 *sq.*; xxx. 9); and Ezekiel uses similar language
., xxxvii.), but that such passages do not necessarily
more than that the Davidic dynasty shall be con-
in the time of restoration under a series of worthy
s seems clear from the way in which Ezekiel speaks
prince in chaps. xlv., xlvi. As yet we have no fixed
e of a personal Messiah, but only material from
such a doctrine might by and by be drawn. The
is view of the kingship is still essentially the same

ation

re are other parts of the Old Testament - notably
viii., xii. - in which the very existence of a human
ip is represented as a departure from the ideal of a
t theocracy. And so, in and after the exile, when
narchy had come to an end, we find pictures of the
days in which its restoration has no place. Such is
eat prophecy of Isa. xl. lxvi., in which Cyrus is the
ol of Jehovah, and the grace promised to David is
rred to ideal Israel ("the servant of Jehovah") as a
(Isa. lv. 3). So too there is no allusion to a human
ip in Joel or in Malachi, the old forms of the
w state were broken, and religious hopes expressed
lves in other shape.[1] In the book of Daniel it is
ive Israel that appears under the symbol of a "son
n," and receives the kingdom (vii. 13, 18, 22, 27).
ntime, however, the decay and ultimate silence of the
prophetic word concurred with the prolonged
al servitude of the nation to produce a most
important change in the type of the Hebrew re

Z. f. A Tliche Wiss., 1881–82. Compare Dan. ix. 2 for the a
older prophecies in the solution of new problems of faith.

led that hope into certain fixed forms which were with a literalness not contemplated by the prophets elves. It was, however, only very gradually that gure and name of the Messiah acquired the pro- ce which they have in later Jewish doctrine of the nings and in the official exegesis of the Targums. In ery developed eschatology of Daniel they are, as we seen, altogether wanting, and in the Apocrypha, both e and after the Maccabee revival, the everlasting e of David's house is a mere historical reminiscence h xlvii. 11; 1 Mac. ii. 57). So long as the wars of endence worthily occupied the energies of the Pales- Jews, and the Hasmonæan sovereignty promised a re of independence and felicity under the law, in the people were ready to acquiesce, at least, till the a new prophet (1 Mac. xiv. 41), the hope that con itself with the house of David was not likely to rise sh life, especially as a considerable proportion of the ery numerous passages of Scripture which speak ideal king might with a little straining be applied rising star of the new dynasty (comp the language Mac. xiv. 4 15). It is only in Alexandria, where ews were still subject to the yoke of the Gentile, t this time (c. 140 B.C.) we find the oldest Sibylline (iii. 652 *sq.*) proclaiming the approach of the ous king whom God shall raise up from the East xli. 2) to establish peace on earth and inaugurate the gnity of the prophets in a regenerate world. The Messiah is still lacking, and the central point of the ecy is not the reign of the deliverer but the subjec f all nations to the law and the temple.[1]

h the growing weakness and corruption of the onæan princes, and the alienation of a large part of ation from their cause, the hope of a better kingship s to appear in Judæa also; at first darkly shadowed n the *Book of Enoch* (chap. xc.), where the white the future leader of God's herd after the deliverance the heathen, stands in a certain contrast to the in- ate sovereignty of the actual dynasty (the horned); and then much more clearly, and for the first time se of the name Messiah, in the *Psalter of Solomon*, ief document of the protest of Pharisaism against its es the later Hasmonæans. The struggle between the sees and Sadducees, between the party of the scribes he party of the Hasmonæan aristocracy, has been bed in ISRAEL (vol. xiii. p. 423 *sq.*). It was a gle for mastery between a secularized hierarchy on ne hand, to whom the theocracy was only a name, and whole interests were those of their own selfish politics, n the other hand a party to which God and the law all in all, and whose influence depended on the main re of the doctrine that the exact fulfilling of the law ding to the precepts of the scribes was the absorbing on of Israel. This doctrine had grown up in the al nullity of Judæa under Persian and Grecian rule, o government that possessed or aimed at political endence could possibly show constant deference to inutilities of the schoolmen. The Pharisees themselves not but see that their principles were politically ent; the most scrupulous observance of the Sabbath, ample—and this was the culminating point of legality ld not thrust back the arms of the heathen. Thus party of the scribes, when they came into conflict an active political power, which at the same time ed to represent the theocratic interests of Israel, were elled to lay fresh stress on the doctrine that the true erance of Israel must come from God and not from We have seen indeed that the legalism which accepted Jehovah as legislator, while admitting that his ex sovereignty as judge and captain of Israel was to t dormant, would from the first have been a self dest position without the complementary hope of a vindication of divine justice and mercy, when the Israel should return to reign over his people fo Before the Maccabee revival the spirit of national so dead that this hope lay in the background, the and devotional aspects of religion under the law h first place, and the monotony of political servitude ga occasion for the observation that a true nation requires a personal leader as well as a written law now the Jews were a nation once more, and nationa came to the front. In the Hasmonæan sovereignt ideas took a political form, and the result was the ization of the kingdom of God for the sake of a har rapacious aristocracy. The nation threw itself on t of the Pharisees; but it did so in no mere sp punctilious legalism, but with the ardour of a n enthusiasm deceived in its dearest hope, and turn help from the delusive kingship of the Hasmonæ the true kingship of Jehovah, and to His vicegere king of David's house. It is in this connexion th doctrine and name of the Messiah appear in the *of Solomon*. The eternal kingship of the house of so long forgotten, is seized on as the proof th Hasmonæans have no divine right.

"Thou, Lord, art our king for ever and ever. The choose David as king over Israel, and swarest unto him con his seed for ever that his kingship should never fail befo And for our sins sinners (the Hasmonæans) have risen up taking with force the kingdom which Thou didst not pro them, profaning the throne of David in their pride. But Lord, will cast them down and root out their seed from t when a man not of our race (Pompey) rises up against the Behold, O Lord, and raise up their king the Son of David at that Thou hast appointed, to reign over Israel Thy servant, him with strength to crush unjust rulers, to cleanse Je from the heathen that tread it under foot, to cast out sinn Thy inheritance, to break the pride of sinners and all their as potter's vessels with a rod of iron (Ps. ii. 9), to destroy less nations with the word of his mouth (Isa. xi. 4), to holy nation and lead them in righteousness. . . He ha them by tribes in the land, and no stranger and foreigner sh with them; he shall judge the nations in wisdom and righte The heathen nations shall serve under his yoke, he shal the Lord before all the earth, and cleanse Jerusalem in holi the beginning. From the ends of the earth all nations sh to see his glory and bring the weary sons of Zion as gifts 3 *sq.*): to see the glory of the Lord with which God hath him, for he is over them a righteous king taught of God days there shall be no unrighteousness in their midst, for all holy, and their king the anointed of the Lord (χριστὸς κύ translation of משיח יהוה). He shall not trust on his as and bowmen, nor heap up gold and silver for war, nor put dence in a multitude for the day of war. The Lord's king his hope. . . He is pure from sin to rule a great people, t governors and destroy sinners by his mighty word. In all he is free from offence against his God, for He hath m strong by the Holy Spirit. . . His hope is in the Lo can do aught against him. Strong in deeds and mighty in of the Lord, he feedeth the flock of the Lord in truth and r ness, and suffereth not one of them to stumble in the pas So it beseemeth the king of Israel whom God hath chose the house of Israel. . . God hasten His mercy on deliver them from the uncleanness of profane foes. The Lo king for ever and ever." *Psalt. Sol.* xvii.

This conception is traced in lines too firm to be th first essay; it had doubtless grown up as an integral the religious protest against the Hasmonæans. An the polemical motive is obvious, and the anonymous prophecy against the legitimacy of a non Davidic is quite in the manner of the scribes, the spirit of th fervour which inspires the picture of the Messiah is and deeper than their narrow legalism. In a wo Jewish doctrine of the Messiah marks the fu Pharisaism with the national religious feeling

[1] In *Sibyll.*, iii. 775, *νηόν* must undoubtedly be read for *υἱόν*.

e revival. It is this national feeling that, claim-
der against the Romans as well as deliverance
Sadducee aristocracy, again sets the idea of the
rather than that of resurrection and individual
on in the central place which it had lost since the
. Henceforward the doctrine of the Messiah is
the centre of popular hope and the object of
al culture. The New Testament is the best
of its influence on the masses (see especially Matt.
and the exegesis of the Targums, which in its
gs doubtless reaches back before the time of
hows how it was fostered by the Rabbins and
in the synagogues.[1] Its diffusion far beyond
, and in circles least accessible to such ideas, is
y the fact that Philo himself (*De Præm. et Pœn.*,
es a Messianic interpretation of Num. xxiv. 27
It must not indeed be supposed that the doctrine

Akiba (comp. Luke xxi. 8) These hopes were
nched in blood; the political idea of the Messiah,
er of the Jewish state, still finds utterance in the
ver of every Jew (the *Shemône Esre*), and is en-
the system of Rabbinical theology; but its his-
nificance was buried in the ruins of Jerusalem.[2]
e proof written in fire and blood on the fair face
ne that the true kingdom of God could not be
n the forms of an earthly state, and under the
s of national particularism, was not the final
of the hope of the Old Testament. Amidst the
ulsions of political Judaism a new and spiritual
n of the kingdom of God, of salvation, and of the
of God's anointing, had shaped itself through the
, the death, and the resurrection of Jesus of
. As applied to Jesus the name of Messiah lost
itical and national significance, for His victory over
, whereby He approved himself the true captain
om, was consummated, not amidst the flash of
words or the lurid glare of the lightnings of Elias,
but in the atoning death through which He entered into the heavenly glory. Between the Messiah of the Jews and the Son of Man who came not to be ministered to but to minister, and to give his life a ransom for many, there was on the surface little resemblance; and from their standpoint the Pharisees reasoned not amiss that the marks of the Messiah were conspicuously absent from this Christ. But when we look at the deeper side of the Messianic conception in the *Psalter of Solomon*, at the heartfelt longing for a leader in the way of righteousness and acceptance with God which underlies the aspirations after political deliverance, we see that it was in no mere spirit of accommodation to prevailing language that Jesus did not disdain the name in which all the hopes of the Old Testament were gathered up. The kingdom of God is the centre of all spiritual faith, and the perception that that kingdom can never be realized without a personal centre, a representative of God with man and man with God, was the thought, reaching far beyond the narrow range of Pharisaic legalism, which was the last lesson of the vicissitudes of the Old Testament dispensation, the spiritual truth that lay beneath that last movement of Judaism which concentrated the hope of Israel in the person of the anointed of Jehovah.

It would carry us too far to consider in this place the details of the Jewish conception of the Messiah and the Messianic times as they appear in the later apocalypses or in Rabbinical theology. See for the former the excellent summary of Schurer, *Neutest. Zeitgeschichte*, §§ 28, 29 (Leipsic, 1874), and for the latter, besides the older books catalogued by Schurer (of which Schoettgen, *Horæ*, 1742, and Bertholdt, *Christologia Judæorum*, 1811, may be specially named), Weber, *Altsynagogale Theologie* (Leipsic, 1880). For the whole subject see also Drummond, *The Jewish Messiah* (London, 1877), and Kuenen, *Religion of Israel* chap. xii. For the Messianic hopes of the Pharisees and the *Psalter of Solomon* see especially Wellhausen, *Pharisäer und Sadducäer* (Greifswald, 1874). In its ultimate form the Messianic hope of the Jews is the centre of the whole eschatology, embracing the doctrine of the last troubles of Israel (called by the Rabbins the "birth pangs of the Messiah"), the appearing of the anointed king, the annihilation of the hostile enemy, the return of the dispersed of Israel, the glory and world-sovereignty of the elect, the new world, the resurrection of the dead, and the last judgment. But even the final form of Jewish theology shows much vacillation as to these details, especially as regards their sequence and mutual relation, thus betraying the inadequacy of the harmonistic method by which they were derived from the Old Testament and the stormy excitement in which the Messianic idea was developed. It is, for example, an open question among the Rabbins whether the days of the Messiah belong to the old or to the new world (הָעוֹלָם הַזֶּה or הָעוֹלָם הַבָּא), whether the resurrection embraces all men or only the righteous, whether it precedes or follows the Messianic age. Compare MILLENNIUM.

We must also pass over the very important questions that arise as to the gradual extrication of the New Testament idea of the Christ from the elements of Jewish political doctrine which had so strong a hold of many of the first disciples—the relation, for example, of the New Testament Apocalypse to contemporary Jewish thought. A word, however, is necessary as to the Rabbinical doctrine of the Messiah who suffers and dies for Israel, the Messiah son of Joseph or son of Ephraim, who in Jewish theology is distinguished from and subordinate to the victorious son of David. The developed form of this idea is almost certainly a product of the polemic with Christianity, in which the Rabbins were hard pressed by arguments from passages (especially Isa. liii.) which their own exegesis admitted to be Messianic, though it did not accept the Christian inferences as to the atoning death of the Messianic king. That the Jews in the time of Christ believed in a suffering and atoning Messiah is, to say the least, unproved and highly improbable. See, besides the books above cited, De Wette, *Opuscula*; Wünsche, *Die Leiden des Messias*, 1870. The opposite argument of King, *The Yoke of Zechariah* (Cambridge, 1852), App. A, does not really prove more than that the doctrine of the Messiah Ben Joseph found points of attachment in older thought. METALLURGY, a branch of applied science
object is to describe and scientifically criticize the m
used industrially for the extraction of metal fr
ores. Of the large number of metals enumerated
handbooks of chemistry, the vast majority, of c
outside its range; but it is perhaps as well for us to
out that metallurgic discussion, even
"metallic," as applied to compounds, has a res
meaning, being exclusive of all the light metals, al
one of these, namely aluminium, is being manufa
industrially. The following table enumerates in th
of their importance the metals which our subject at

rstood to include; the second column in each case
he chemical characters of the native compounds
, italics indicating ores of subordinate importance.
m "oxide" must be understood to include carbon
lrate, and occasionally (when marked in the table
silicate.

Metal	Character of Ore
	Oxides, *sulphide*
	Complex sulphides, also oxides, *metal*
	Sulphide and reguline metal, *chloride*
	Reguline metal
	Sulphide metal bi-carbonate, *sul phide*, &c
	sulphide, oxide

ave separated the last two from the rest because
thod, used for their preparation are more of the
of laboratory operations, and because we do not
include these in our general exposition of metal
inciples. The history of metallurgy, up to the
ent time, is obscure. It is only since about the
ng of the century that the art has come to be at
ntifically criticized, and in the case of the most
nt processes all that science has been able to do
n merely to put her stamp upon what experience
ng found to be right. Great and brilliantly
ul scientific efforts in the synthetic line are not
, but they all belong to recent times. Science, by
nature, aim at publicity, empiricism at all times
e the reverse, hence a history of the development
art of metallurgy does not and cannot exist. A
tonical note on the discovery of certain of the useful
are given in the introduction to METALS (*q.v.*).

al Sequence of Operations. Occasionally metallic
sent themselves in the shape of practically pure
t nuggets, from which the accompanying matrix or
e can be detached by hand and hammer. But
a rare exception. In most cases the "ore," as it
ut of the mine, is simply a mixture of ore proper
gue in which the latter not unfrequently predomi
to such that it is not the gangue but the ore that
ecupies the position of what the chemist would call
parity. Hence, in general, it is necessary, or at
pedient, to purify the ore as such before the libera
the metal is attempted. Most metallic ores are
ally heavier than the impurities accompanying them,
is purification may be (and generally is) effected
nding the crude ore to a fine enough powder to
the metallic from the earthy part, and then washing
e latter by a current of water, as far as possible.
case of a "reguline" ore, such as auriferous quartz,

t the metal itself, and require only to be melted
nd cast into ingots to be ready for the market.
owever, in a rare case, the vast majority of ores
chemical compounds, which for the extraction of
etals demand chemical treatment. The chemical
ns involved may be classified as follow

ting Operations.—The ore, along in general with
nd of "flux," is exposed to the direct action of a
l fire. The fire in most case has a chemical, in
n to its obvious physical function. It is intended
to burn away certain components of the ore; in
ase it must be so regulated as to contain a sufficien
excess of unburned oxygen; or it is meant to de
("reduce") the ore, when the draught must be res
so as to keep the ore constantly wrapped up in comb
flame gases (carbonic oxide, hydrogen, marsh gas
The vast majority of the chemical operations of meta
fall into this category, and in these processes other
reducing agents than those naturally contained in t
(or wind) are only exceptionally employed.

2. *Amalgamation.* The ore by itself (if it happ
be a reguline one), or the ore plus certain reagents
does not), is worked up with mercury so that the m
obtained ultimately as an amalgam, which can be sep
mechanically from the dross. The purified amalg
subjected to distillation, when the mercury is recove
a distillate while the metal remains.

3. *Wet Processes.* Strictly speaking, certain anal
tion methods fall under this head; but, in its or
acceptance, the term refers to processes in which the
is extracted either from the natural ore, or from the
it is after roasting or some other preliminary treatme
means of an aqueous acid or salt solution, and fro
solution precipitated generally in the reguline form
some suitable reagent.

Few methods of metal extraction at once yield
product. What as a rule is obtained is a more
impure metal, which requires to be "refined" to b
fit for the market. We now pass to the individua
sideration of the several steps referred to.

Comminution of Ores. Assuming the ore to be given in th
of large lumps, these must first be broken up into small st
about the size of those used for macadamizing a road) before t
go to the grinding mill. This formerly used to be done by
work, nowadays it is preferably effected by means of an Am
invention called the stone breaker (fig. 1). This consists essent
two substantial vertical iron plates, one is fixed, the other is co
with an excentric worked by an engine so as to alternately dash
and recede from the former. The lumps of ore, in passing t
this jaw like contrivance, are broken up into smaller fragment

he production of a relatively fine powder the pounding-mill ently used, which, in its action, is analogous to a mortar and The mortar is a rectangular trough, while the pestle is by a parallel set of heavy metal or metal-shod beams, by means of a revolving cylinder with cogs catching pro on the beams) are lifted up in succession and then by their own weight so as to pound up the ore in the trough. is supplied from a prismatic reservoir with a sloping leading into a canal through which the stones slide into gh A current of water, which constantly flows into the from below, lifts up the finer particles and carries them er the edge of the trough into a settling tank.

bject pursued in powdering an ore is to prepare it for being by washing. But the velocity with which a solid particle ough water depends on its size as well as on its specific an increase in either accelerating the fall hence, where rence in specific gravity between the things to be separated the washing must be preceded by a separation of the ore- into portions of approximately equal fineness. This is often by passing the ore through a system of sieves of different f mesh superposed over one another, the coarser sieve cupying the higher position. Sometimes the sieves are "go dry," sometimes they are aided in their action by a of water which, more effectually than mere shaking, pre- herence of dust to coarser parts

er contrivance is the "Drum" (fig. 2). A long perforated ylinder made of sheet iron, open at both ends, is suspended, ing position, by a revolving shaft passing through its axis. of the perforations is generally made to increase in passing upper to the lower belts of the cylinder. While the drum

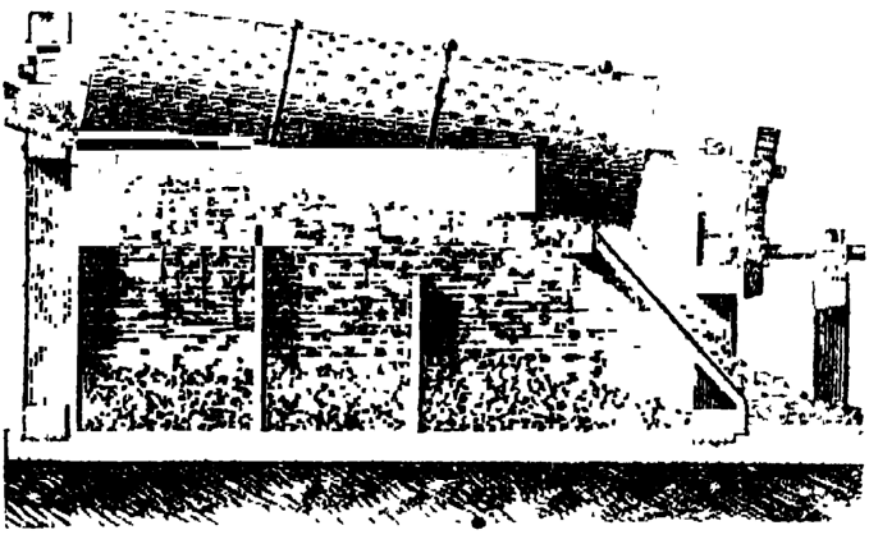

Fig. 2.—Drum.

ring, the ore, suspended in water, flows in at the upper end, travelling down it casts off first its finest and then its coarser ne coarsest only reaching the exit at the lower end. The grades of powder produced fall each into a separate division collecting tank.

drum, of course, is subject to endless modifications. A genious combination is H. E. Taylor's "Drum Dressing " (fig. 3). It consists of three truncated cone shaped , fixed co-axially to the same horizontal revolving shaft,

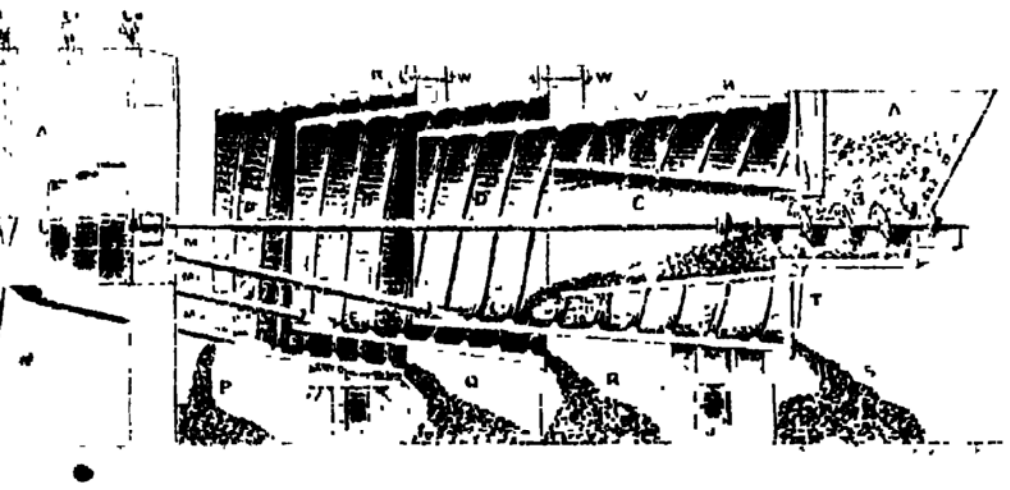

Fig. 3.—Taylor's Drum Dressing Machine.

he narrow end of No. 1 projects into the wider end of No. 2, 2 similarly into No. 3. The drums are not perforated, but ed inside with screw-threads formed of strips of sheet metal fixed edgeways to the drum. The ore grit to be dressed i in a hopper A, and from it, by a worm B fixed to the r shaft, is being screwed forward into a short fixed truncate projecting into the revolving drum No. 1, into which it a constant current. The rotary motion of the drum t convey the ore along the spiral path prescribed by the scre towards the other end, and from it into drum No. 2, an But the ore in each drum meets with a jet of water E n it the opposite way, and the effect is that, in each dr lighter parts follow the water, and with it run off entrance edge to be collected in a special tank, while the parts roll down the spiral path toward the next drum to further parting. The tank or pit for drum 1 receives t and lightest parts, that of drum 2 a heavier, that of d still heavier portion, while only the very heaviest matt its way out of the exit end of No. 3 into a fourth receptacl

Of the large number of other ore-dressers, only two need tioned here.

The "Clausthal Turn-Table" consists of a circular table, face of which rises from the periphery towards the centre form a very flat cone of about 170°, which is fixed co-axially tical rotary shaft. At the apex of the table, surrounding th but independent of its motion, there is a circular trough of sh divided into two compartments, one receives a stream carrying the ore, the other a supply of pure water. A lar lar trough of sheet zinc is placed below the periphery of th so as to receive whatever may fall over the edge. It also is into compartments, as shall be explained further on. Suppo table to be at rest, a sector of about 60° of it would be co run over by the ore mud out of the first compartment of th trough. This mud current would suffer partial separati heavier and lighter parts: such ore resting in the hig poorer in the lower latitudes, and a still poorer ore falling periphery into the lower trough. The same happens w moving table; only each sector of such partially analysed or goes further purification by passing through about 90° of shower. After passing this, it meets with a perforated fixe pipe going up radially to about half the radius of the table pipe also carries sweeping brushes, so that the belt of ore f lower latitudes of the table is swept off into the corresponding of the receiving trough. What of ore remains on the higher l subsequently meets with a similar arrangement which swee into its compartment. If the table turns from the left to th and we follow the process, beginning at the left edge of the compartment, it will be seen that a first sector of the r trough gathers the light dross, a succeeding one an inter product, a third the most highly purified ore. The "intern is generally run into the ore-mud trough of a second tab further analysed.

In the "Continuous Wash Pumps" (Continuirliche Set of the Harz, three funnel shaped vessels (one of which is s fig. 4) are set in a frame beside one another, but at differen so that any overflow from No. 1 runs into No. 2 and the No. 3. Each funnel communicates below with it own c ment of a common cistern.

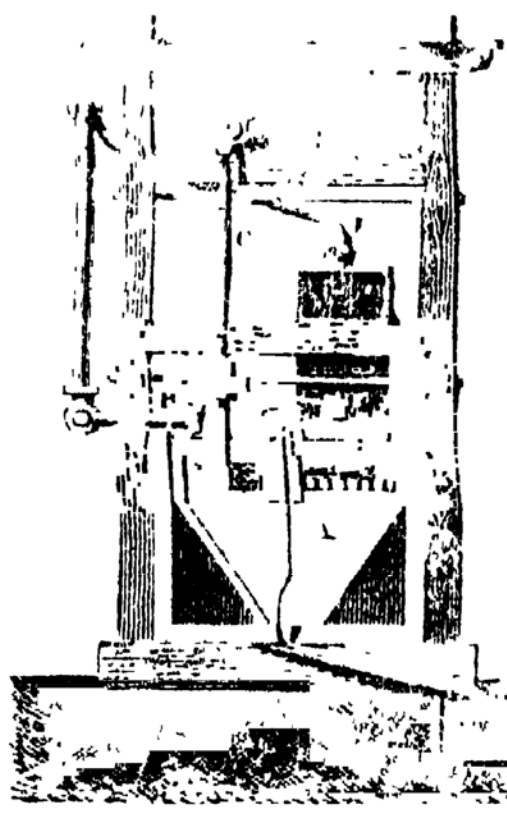

Fig. 4.—Continuous Wash

Into each funnel a riddle with narrow meshes is inserted somewhere near the upper end, while, beside the riddle, there is a pump of short range, which, by means of an excentric, is worked so that the piston alternately goes rapidly down and slowly up. The mode of working is best explained by an example. At Brunnenberg in Rhenish Prussia the apparatus serves to separate a complex ore into the following four parts, which we enumerate in the order of their specific gravities (1) galena (the heaviest), (2) pyrites, (3) blende, (4) dross. Sieve No. 1 is charged with granules of galena, just large enough not to slip through the meshes, No. 2 similarly with granules of pyrites, No. 3 with those of blende. The crude ore mad sieve 1; the jerking action of the pump alternately, t particles up into the water and allow them to fall. The naturally come down first, but whilst in motion taking nothing will pass through the bed of galena but what i as heavy as galena itself. In a similar manner No. 2 an

sift out the pyrites and the blende respectively, so that nothing but dross runs off ultimately. The apparatus is lo its work with a wonderful degree of precision, and of susceptible of wider application, but it ceases to work raw material is a slime so fine that the particles fall too

of Producing High Temperatures.—Most of what is to be this topic has already been anticipated in the articles FURNACE, and BELLOWS; but a few notes may be added ally metallurgic points.

Materials. In a metallurgic furnace the working parts must be made of special materials capable of withstanding high temperatures to which they are exposed and the the fluxes which may be used. No practically available fully meets both requirements, but there is no lack of fire proof substances.

tive stones, a pure quartzose sandstone, free from marl, named as being well adapted for the generality of structures; sandstone, or indeed any kind of fire proof stone, is not at hand. What is more readily procured, and consequently dely used, is refractory brick, made from "fire-clay." The ntial chemical feature of fire-clays is that in them the clay always some kind of hydrated silicate of alumina) is associated ly small proportions of lime, magnesia, ferrous oxide, or oxides. If the percentage of these goes beyond certain the bricks, when strongly heated, melt down into a slag sence of free silica, on the other hand, adds to their refrac-

In fact the best fire bricks in existence are the so-called ricks, which consist substantially of silica, contaminated h just enough of bases to cause it to frit together on being Dinas bricks, however, on account of their high price, are for special cases involving exceptionally high temperatures. ordinary fire bricks those from Stourbridge enjoy the reputation. It follows from what has just been said that, allurgic furnace, lime mortar cannot be used as a cement, t be replaced by fire clay paste.

construction of cupels, reverberatory furnaces, &c., only eral brick made of built bricks, and this work coated over with some kind of special fire proof and of material, such as bone ash, a mixture of baked fire-clay s or graphite, or of quartz and very highly silicated slags, &c. oldings are put on in a loose powdery form, and then stamped hey offer the advantage that, when worn out, they are easily and renewed. The powerful draught which a metallurgic ls can be produced by a chimney, where the fuel forms a y shaft layer spread on grating; but, when ked deep masses of fuel or fuel and ore have to be kept blast becomes indispensable.

Blowing Machines. The efficiency of a chimney is measured by the V with which the air ascends through it, multiplied by its and the former is in roughly approximate accordance formula

$$V = k\sqrt{2gh(T - T_0)/T_0},$$

stands for the height of the chimney, g for the acceleration ty (32·2 feet per second), and T and T_0 for the absolute tures (meaning the temperatures counted from -273° C.) of within and the air without the chimney respectively, while tor meant to account for the resistances which the air, in ress through the furnace, &c., has to overcome. In practice be mean temperature of the chimney gases, which ally is not unobjectionable, but the weakest point in the is the smallness and utter inconstancy of the factor k, according to Peclet, generally assumes some value of the , &c. Yet the formula is of some use as enabling see the way in which V depends on h and $(T - T_0)/T_0$, con- to see, for instance, how deficient chimney height may be sated for by an increase of temperature in the chimney and *vice versa*.

Blowing Machines. Of the several kinds of blowers described BELLOWS (*q.v.*), the "fans" are the best means for producing olumes of wind of relatively small but steady pressure: ws" are indicated in the case of work on a relatively small quiring moderate wind pressure: while the "cylinder blast" n where large masses of high-pressure wind are required. ghly interesting blowing machines, however, are omitted in cle, which may be shortly described here.

"Water Blast" (Wassertrommelgebläse) is interesting ally, having been used metallurgically in Hungary for enturies. A mass of water, stored up in a reservoir, is made down continuously through a high narrow vertical shaft air holes at its upper end. The vertical column of water air through these holes and carries it down with it into a inverted tub standing in a reservoir kept at a constant Air and water there separate, the former flowing away pipe into a wind-box, from which it is led to its destina-

The "Cagniardelle" (figs. 5, 6), so called from its inventor Cagniard Latour, also utilizes water to carry air, but in quite another way. By means of a round shaft passing through its axis, a cylindrical vessel of sheet metal is suspended slantingly in a mass of water, so that its lower end is fully immersed, while of the upper end the sole above the upper side of the shaft is uncovered. The space between shaft and drum is converted into a very wide screw-shaped canal by a band of sheet metal hermetically fixed edgeways to the two. Both the top and the bottom end of the drum are partially closed by

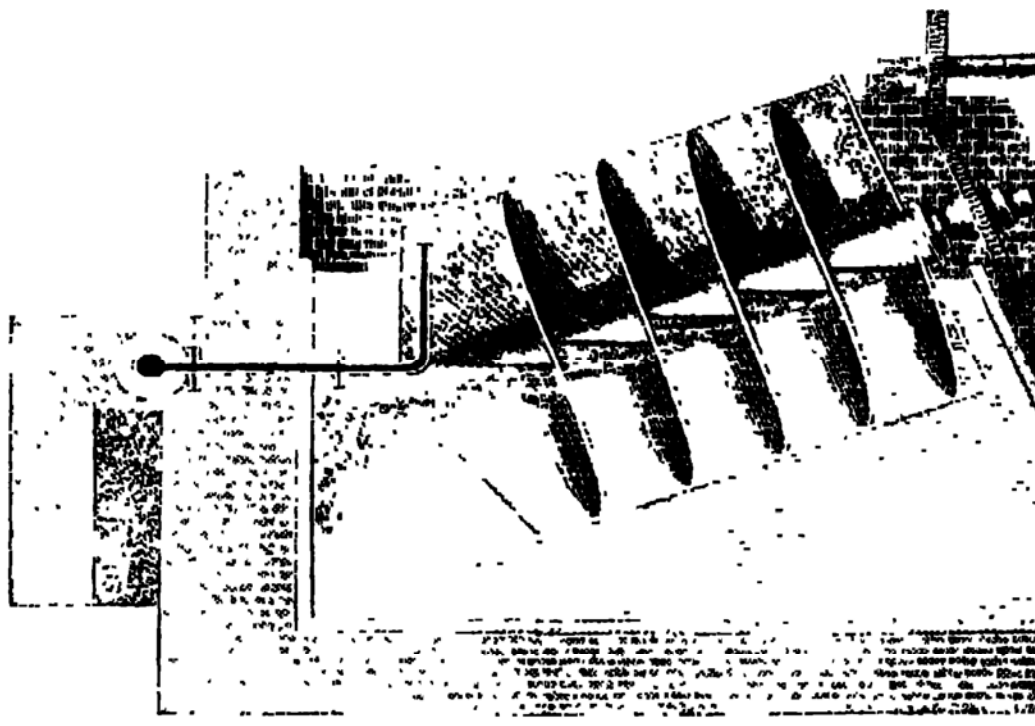

FIG. 5.—Cagniardelle.

bottoms soldered or riveted to the respective edges; the one leaves a ring-shaped opening between its edge and the which serves for the introduction of a fixed air-pipe, bent s reach up to near the top of the drum's air-space; in the bottom three quadrants are closed, the fourth is open. Sup the screw canal, traced from below, to go from the left to the the drum is made to revolve in the same sense, and the effect in each revolution, the screw-canal at its top end swallows a volume of air which, by the succeeding entrance of the water of course, moves relatively to the screw is pushed towards and ultimately into the air space at the bottom end. The Cagniardelle yields a perfectly continuous blast, and, as it is not encumbered with any dead resistances except the friction of the shaft against its bearings (which can be reduced to very little) and the very slight friction of the water against the screw-canal, it utilizes a very large percentage of the energy spent on it. This percentage, according to experiments by Schwamkrug, amounts to from 75 to 84·5; in the case of the cylinder blast it is 60 to 65 per cent.; with b about 40 per cent.; with the "Wassertrommelgebläse" 10 to cent. "Wassertrommelgebläse" stands last in efficiency; but we must not forget that it alone directly native energy, while, in the cylinder blast, for example, 10 of work done by the steam-engine involve a vastly greater spent on the engine as heat.

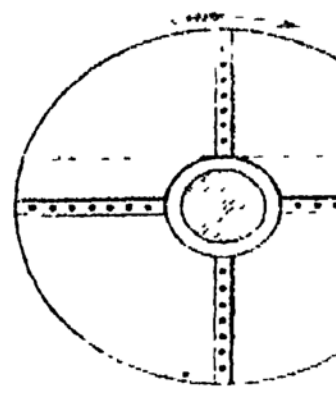

FIG. 6.

To maintain a desired temperature in a given furnace cha a certain manner, the introduction of a certain volume of unit of time is necessary. But this quantity, in a given bl machine, is determined by the over-pressure of the wi measured by a manometer, the velocity of the wind being a mately proportional to $\sqrt{M/(B + M)}$, where M stands for the of the mercury-manometer, and B for that of the baro Hence the practical metallurgist, in adjusting his blast, has n to do but to see that the manometer shows the reading wh previous trials, has been proved to yield an adequate supply o

Fuel. In some isolated cases the ore itself, by its comb supplies the necessary heat for the operation to be performe it. Thus, for instance, the roasting of blackband iron-s effected by simply piling up the ore and setting fire to it, the ore is at the same time its own furnace and fuel: Bessemer process of steel-making, the burning carbon of t iron supplies the heat necessary for its own combustion. similar process has been tried experimentally, and not success, for the working up of certain kinds of pyrites. B rule, the high temperatures required for the working of ores duced by the combustion of extraneous fuel, such as wood charcoal, coal, coke. Of these four, wood-charcoal is of the applicability, but not much used in Britain on accoun high price. High-class coke or pure anthracite, volume for

highest temperature. Wood or coal is indicated when a ous flame is one of the requisites. Obviously fuel of the d and quality gives a higher calorific intensity when, before deprived by drying of its moisture, or when it is used in ion with a hot instead of a cold blast. This latter prin every one knows, is largely discounted in the manufacture on, where nowadays coal, with the help of the hot blast, to do what formerly could only be effected with charcoal or For further information see FUEL and IRON.

cal Operations. In regard to processes of amalgamation et-way processes, we have nothing to add to what was given vious paragraph;[1] we therefore here confine ourselves, in , to pyro-chemical operations.

ethod to be adapted for the extraction of a metal from its termined chiefly, though not entirely, by the nature of the allic component with which the metal is combined. The case is that of the regulme ores where there is no non element. The important cases are those of GOLD, BISMUTH, RCURY (*q. v.*)

s, Hydrates, Carbonates, and Silicates. All iron and tin ores ll under this heading, which, besides, comprises certain ores r, of lead, and of zinc. In any case the first step consists rting the crude ore to a roasting process, the object of which ove the water and carbonic acid, and burn away, to some t least, what there may be of sulphur, arsenic, or organic The residue consists of an impure (perhaps a very impure) the respective metal, which in all cases is reduced by treatth fuel at a high temperature. Should the metal be present licate form, lime must be added in the smelting to remove a and liberate the oxide.

case of zinc the temperature required for the reduction lies e boiling point of the metal; hence the mixture of ore and agent (charcoal is generally used) must be heated in a ombined with the necessary condensing apparatus. In all r cases the reduction is effected in the fire itself, a tower blast furnace being preferably used. The furnace is charged ernate layers of fuel and ore (or rather ore and flux, see below) and the whole kindled from below. The metallic oxide, y the direct action of the carbon with which it is in contact, cipally by that of the carbonic oxide produced in the lower om the oxygen of the blast and the hot carbon there, is re- o the metallic state; the metal fuses and runs down, with , to the bottom of the furnace, whence both are withdrawn eriodic opening of plug-holes provided for the purpose.

ides.—Iron, copper, lead, zinc, mercury, silver, and antiery frequently present themselves in this state of combin components of a very numerous family of ores which may ed into two sections: (1) such as substantially consist of ulphides, as iron pyrites (FeS_2), galena (PbS), zinc blende innabar (HgS); and (2) complex sulphides, such as the kinds of sulphureous copper ores (all substantially com- or mixtures of sulphides of copper and iron); bournonite, ex sulphide of lead, antimony, and copper; rothgiltigerz, of silver, antimony, and arsenic; fahlerz, sulphides of and antimony, combined with sulphides of copper, silver, nc, mercury, silver; and mixtures of these and other sulwith one another.

e treatment of a sulphureous ore, the first step as a rule is ct it to oxidation by roasting it in a reverberatory or other which, in the first instance, leads to the burning away of at rt of the arsenic and part of the sulphur. The effect on the individual metallic sulphides (supposing only one of these esent) is as follows:—

ose of silver (Ag_2S) and mercury (HgS) yield sulphurous and metal; in the case of silver, sulphate is formed as an diate product, at low temperatures. Metallic mercury, in unstances, goes off as a vapour, which is collected and consilver remains as a regulus, but pure sulphide of silver is ver worked.

lphides of iron and zinc yield the oxides Fe_2O_3 and ZnO as ducts, some basic sulphate being formed at the earlier stages, pecially in the case of zinc. The oxides can be reduced by

e sulphides of lead and copper yield, the former a mixture and normal sulphate, the latter one of oxide and basic . Sulphate of lead is stable at a red heat; sulphate of breaks up into oxide, sulphurous acid, and oxygen. In , neither oxidation process is ever pushed to the end; it is soon as the mixture of roasting-product and unchanged contains oxygen and sulphur in the ratio of $O_2 : S$. The of air is then stopped and the whole heated to a higher ature, when the potential SO_2 actually goes off as sulphurous- and the whole of the metal is eliminated as such. This is largely utilized in the smelting of lead (from galena) and er from copper pyrites. In the latter case, however, the sulphide Cu_2S has first to be produced from the ore, which substantially as follows. The ore is roasted with silica certain proportion of the sulphur is burned away as SO_2, corresponding proportion of oxygen has gone to the metal the ore. Now it so happens that copper has a far greater affi sulphur than iron has; hence any locally produced oxide of as long as sufficient sulphide of iron is left, is sure to be reco into sulphide, and the final result is that, while a large quan oxidized iron passes into the slag, all the copper and part of separate out as a mixed regulus of Cu_2S and FeS ("mat") regulus, by being fused up repeatedly with oxidized copper rich copper slags (virtually with CuO and silica), gradually up the whole of its iron, so that ultimately a regulus of pure phide of copper, Cu_2S ("fine mat"), is obtained, which is up for metal as above explained.

4. Sulphide of antimony, when roasted in air, is convert a kind of alloy of sulphide and oxide; the same holds f only its oxysulphide is quite readily converted into th oxide Fe_2O_3 by further roasting. Oxysulphide of antimo suitable processes, can be reduced to metal, but these proce rarely used, because the same end is far more easily obta "precipitation," *i.e.*, withdrawing the sulphur by fusi metallic iron, forming metallic antimony and sulphide Both products fuse, but readily part, because fused antim far heavier than fused sulphide of iron is. A precisely method is used occasionally for the reduction of lead from Sulphide of lead when fused together with metallic iron proportion of 2Fe : 1PbS yields a regulus (2Pb) and a Fe_2S, which, however, on cooling, decomposes into FeS ordinary sulphide and Fe parts of finely divided iron. W have just been explaining are only two special cases of general metallurgic proposition. According to Fournet, an the metals copper, iron, tin, zinc, lead, silver, antimony, in general, is capable of desulphurizing or precipitating partially) any of the others that follows it in the series jus and it does so the more readily and completely the gre number of intervening terms. Hence, supposing a comple ture of these metals to be melted down under circumstance ting of only a partial sulphuration of the whole, the copper best chance of passing into the "mat," while the arsen first to be eliminated as such, or, in the presence of oxid oxide.

Arsenides. Although arsenides are amongst the com impurities of ores generally, ores consisting essentially of a are comparatively rare. The most important of them are double arsenides of cobalt and nickel, which in practice, l are always contaminated with the arsenides or other compo foreign metals, such as iron, manganese, &c. The general working these ores is as follows. The ore is first roasted l when a part of the arsenic goes off as such and as oxi volatile), while a complex of lower arsenides remains. This is now subjected to careful oxidizing fusion in the presence or some other fusible solvent for metallic bases. The diffe the several metals are oxidized away and pass into the silicates) in the following order, first the manganese, secon iron, thirdly the cobalt, lastly (and very slowly) the nick at any stage the as yet unoxidized residue of arsenide asst form of a fused regulus, which sinks down through the s "speis." (This term, as will readily be understood has t meaning in reference to arsenides as "mat" has in regard to sul By stopping the process at the right moment, we can pr speis which contains only cobalt and nickel, and if at th also the flux is renewed we can further produce a speis wh tains only nickel and a slag which substantially is one only. The composition of the speises generally varies from to $AsMe_2$, where "Me" means one atomic weight of metal so that in general $1Me \; xFe + yCo + zNi$, where $x + y + z$ silicecous cobalt is utilized as a blue pigment called "smal nickel-speis is worked up for metal, preferably by wet proc

Minor Reagents. Besides the oxidizing and reducing agen rally present in the fire, and the "fluxes" added for the pr of slags, there are various minor reagents; of which the i portant may be noticed here. One—namely, metallic n desulphurizer—has already been referred to.

Oxide of lead, PbO (litharge), is largely used as an oxidizin At a red heat, when it melts, it readily attacks all metals silver and gold, the general result being the formation of oxide and of a mixed regulus, a distribution, in other w both the lead and the metal acted on between slag and More important and more largely utilized is its action on sulphides, which, in general, results in the formation things besides sulphurous acid gas, viz., a mixed oxide slag ing the excess of litharge, a regulus of lead (which may bismuth and other more readily reducible metals, and litharge is not sufficient for a complete oxidation, a comprising the more readily sulphurizable metals. Oxide being a most powerful solvent for metallic oxides generally

[1] Examples are given in GOLD and COPPER. See also SILVER.

used for the separation of silver or gold from base metallic

ld lead is to metals generally what oxide of lead is to oxides. It accordingly is available as a solvent for so to ing up small particles of metal diffused throughout a mass or other dro and uniting them into one regulus. This y leads u to consider the process of "cupellation" which s the solvent powers of both metallic lead and its oxide. ocess a ives for the extraction of gold and silver from them ith ba e metals such a copper, antimony, &c. The first o fu e up the alloy with a certain proportion of lead, which mined by the weight of base metal to be eliminated, and s sufficient to produce a lead-alloy of low fu ing point. This heated on a shallow oval-shaped bed of bone earth to red- d at the temperature subjected to the a tion of an. The tal copper, &c are oxidized fi s the first portion as an e ium containing little oxide of lead, the latter in the form ution in molten litharge. Le ter, in general, less oxidiz- on the other ha e metals, hence the last instalment of liquid which runs off is pure, and the ultimately remaining regu- ts of silver and gold only. These latter may be separated c and or boiling oil of vitriol, which converts the silver into salts and leave the gold.

e of iron, and also binoxide of manganese, are used for the ation of pyrites. The oxygen of the reagent burn the of the pig into carbonic acid, while the metal of the become iron and FeO or MnO respectively, the oxides with the silica added as such, or formed by the oxidation lico of the pig, into a fusible slag.

pyrite FeS, is employed for the preliminary concentration of gold diffused throughout slags or base ores. The reagent, the action of the heat, give up one half of its sulphur, duces part of the metallic oxide present. The gold and ite with what is left of protosulphide of iron (FeS) into a ch ; then worked up for the noble metals.

s. Practically speaking, all ores are contaminated with s, of gangue, which in general consists of infusible and consequently, if left unheated in the reduction of ilic part of the ore, would retain more or less of the metal ated throughout or at best foul the furnace. To avoid this, as it goes into the furnace is mixed with "fluxes," so as to convert the gangue into a fusible "slag," which uns down through the fuel with the regulus and separates latter. The quality and proportion of flux should, if pos- so chosen that the formation of the slag sets in only after al has been reduced and melted, or else part of the basic the metal to be extracted may be dissolved by the slag and tion thus be prevented or retarded. Slags are not, as one inclined to think, a necessary evil, if an ore were free from we should add gangue and flux from without to produce a slag, one of its functions is to form a layer on the regulus which it against the further action of the blast or furnace gases. may be arranged under the three heads of (1) fluor-spar , (2) basic fluxes, and (3) acid fluxes.

-spar owes its name to the facility with which it fuses up at with silica, sulphates of lime and barium, and a few sible substances into homogeneous masses. It shows ndency to dissolve basic oxides, such as lime, &c. One part spar liquefies about half a part of silica, four parts of sulphate and one and a half parts of sulphate of baryta. Upon these wide application in metallurgy is founded.

nate of soda (or potash) may be said to be the most power- ux. It dissolves silica and all silicates into fusible On the other hand, borax may be taken as a type for the Most of it heat, when it forms a viscid fluid, it readily s up all basic oxides into fusible complex borates. Now gue of an ore in general consists either of some basic uch as carbonate of lime (or magnesia), ferric oxide, , &c., or of silica (quartz) or some more or less acid silicate, f a mixture of the two classes of bodies. So any kind of ught be liquefied by means of borax or by means of alkaline e, but neither of the two is used otherwise than for assay- hat the practical metal-melter does is to add to a basic the proportion of silica, and to increase or lower the proportion of indirectly, of ferrous or perhaps manganous oxide, which it l for the formation of a slag of the proper qualities. The st possess the proper degree of saturation. In other words, $SiO_2 + nMeO$ (where MeO is an equivalent of base) as a for the potential slag, n must have the proper value. If n mall, *i.e.*, if the slag is too acid, it may dissolve up part of l to be brought out as a silicate; if n is too great, *i.e.*, the basic, it may refuse to dissolve, for instance, the ferrous oxide meant to go into it, and this oxide will then be reduced, metal (iron in our example) contaminate the regulus. In to the problem under discussion, it is worth noting that f lead and copper are more readily reduced to metals than iron Fe_2O_3 is to FeO, the latter more readily to FeO than FeO itself to metal, and Fe_2O_3 more readily to metal than man oxide is. Oxide of calcium (lime) is not reducible at all order of basicity in the oxides (their readiness to go into the precisely the reverse.

Most slags being, as we have seen, complex silicates, it is important problem of scientific metallurgy to determine the re in this class of bodies between chemical composition on t hand and fusibility and solvent power for certain oxides (CaO SiO, &c.) on the other. Now the composition of a silicate stated in an infinite number of ways, but there must be one of formulation which reduces the law to its simplest terms mode adapted by metallurgists is something like the followi we start with the quantity H_2Cl_2 of muriatic acid or the qu H_2SO_4 of sulphuric acid, it is clear that to convert either normal salt we require such a quantity of base as will conve H_2 of the acid completely into water, but the quantity of ba does so is that containing one atomic weight of oxygen. It is reasonable to define the quantities K_2O of potash,[1] Na_2O of CaO of lime, MgO of magnesia, FeO of ferrous oxide, $\frac{1}{2}Al_2O_3$ of alumina, $\frac{1}{2}Fe_2O_3$ (= FeO) of ferric oxide as representing each equivalent" of base also in reference to silica, although silic characteristically indefinite basicity. Most slags are alloys pounds of silicates of Al_2O_3 or Fe_2O_3, and of silicates of pro (CaO, &c.), hence their general composition is

$$n(RO + xSiO_2) + m[(fe \text{ or } al)O + xSiO_2].$$

This introduction will enable the reader to understa following mode of classifying and naming composition in sl

Name	Formula	Oxygen Ratio	
		Base	Acid
I. Singulo silicate	$SiO_2 + 1MO$	1	1
II. Bi-silicates	$SiO_2 + 1MO$	1	2
III. Tri-silicates	$SiO_2 + 1MO$	1	3

The names are the metallurgic ones; scientific chemists de Class I as orthosilicates, Class II. as metasilicates, Class III. as silicates. In the formula M stands for Ky, Ca, Fe, &c., or $\frac{1}{2}$Al or $\frac{2}{3}$Fe, &c., or, shortly, MO for one equivalent of above defined. It should be possible to represent each quali silicate as a function of x, $''$, $'''$, and of the nature of the individu that make up the RO and (fe or al) O respectively. Our knowledge falls far short of this possibility. The problem, a very tough one, the more so as it is complicated by the ex of aluminates, compounds such as $Al_2O_3 3CaO$, in which the a plays the part of acid, and the occasional existence of com of fluorides and silicates in certain slags. The following n the fusibility of simple silicates are taken from Plattner's rese

Of the lime silicates, the tri-silicate melts at 2100° C.; silicate at 2150°.

Magnesia silicates are most refractory. The bi-silicate a silicate melt in the oxyhydrogen flame at 2250°.

Of manganous silicates, the easily fusible bi-silicate is yel red; the tri-silicate is more refractory.

Of cuprous (Cu_2O) silicates, the bi-silicate is violet, and pretty easily; the singulo silicate is red, dense, and rather refr

Cupric silicates, as slags, hardly exist, the CuO being reduced to at least Cu_2O.

Lead silicates all melt readily into yellowish transparent g But they have no standing as slags.

As regards the ferrous silicates, the singulo-silicate (orthos fuses at 1790° (this is about the composition of iron-puddling the bi-silicate is less readily fusible.

Ferric silicates (unmixed) do not exist as slags,—the Fe_2O_3 reduced in the fire to 1FeO, although Fe_2O_3 occasionally r part of the Al_2O_3 in complex silicates.

Alumina silicates are all infusible in even the hottest f fires. They begin to soften in the oxyhydrogen flame at 2400°. But certain aluminates, for instance the salt $3CaO.$ according to Sefstrom, melt at furnace heats.

The fusing points of mixtures of two simple silicates can calculated from those of the components. In many cases it is than either of the latter two. Thus for instance most mag lime silicates fuse, the bi silicate combination (Mg, Ca)OSiO readily.

Alumina silicates become fusible by addition of a sufficien portion of silicate of lime at about 1918°. The singulo-silica bi-silicate combinations melt into grey glasses. Magnesia ac lime, and so, in a more limited sense, do ferrous and mang oxides; but their double compounds with Al_2O_3 and silica ar vised when fused.

Plattner's work is a bold attempt to deal synthetically wi problem here presented, but it does not go the length of e approximate solution. No one seems to have done much t time it; hence in the meantime the metallurgist has, f

[1] Few slags contain more than traces of alkalies.

, to rely on the very numerous analyses which have been slags actually produced (by the rule of thumb) in successful gical operations. For some of such slags also Plattner has ed the fusing points. He found for (1) Freiberg lead slag, lO, $8SiO_2$; oxygen ratio, 3 : 4; melting-point at 1317° C., berg crude slag, $15RO$, $3alO$, $18SiO_2$; oxygen-ratio, 1 : 1, point at 1331° C.; (3) Freiberg black copper slag, $24FeO$, $5SiO_2$; oxygen ratio, 9 10, melting-point at 1338° C.; n-furnace slag, $6CaO$, $3alO$, $9SiO_2$; oxygen-ratio, 1 1, point at 1431° C.[1]

Large Assaying. To assay an ore originally meant to a set of tentative experiments on a small scale in order to the proper mode of working it practically. But nowadays is always used in the sense of an analysis carried out to e the money value of an ore. For this purpose, as many s suffi nt to determine the percentages of the metals for he ore is meant to be worked. But sometimes nothing a complete analysis will do. This holds more especially of on. As this metal is cheap, the value of an ore containing ds as much on the nature and relative quantities of the im- as on the percentage of metal. The proved ate-ness of sulphur sphorus may be worth more than an additional 5 per cent. which latter again would perhaps not compensate for the resence of a large percentage of uncombined silica.

say to be of any value must start with a fair sample of the l sale. The fulfilment of this condition in all cases is The general method is, from say a given shipload of ore, ut (say) half a ton of ore from a large number of different d to crush this large sample into small fragments of uniform ch are well shovelled up together. From different parts of heap a sample of the second order amounting to, say, 20 en drawn, and rendered more homogeneous by finer powder- mixing. From this sample of the second (or perhaps from he third) order quantities of 1 or 2 lb are bottled up for . At the same time the moisture of the ore is determined, e scale, by some conventional method, such as the drying of in an open basin at 100° C., and weighing of the residue as This is done at the sampling place by the firm concerned. yer further pounds up and mixes his sample, and then pro- determine the percentages of moisture and metal in his own e has always the choice between two methods, the dry and For the majority of gold or silver ores, and for cobalt and es almost as a rule, certain dry process tests are preferred ost exact analytically. In almost all other cases it may be t the wet method is susceptible of the higher degree of pre- et even in some of these cases the old dry process tests are l to the present day. For instance, all copper ores in the Isles are sold by the result of the Swansea assay, a kind tion of the process of sulphureous copper ore smelting; and gularly, is adhered to even in the case of such cupriferous s as are worked by the wet way, although the Swansea well known to lose about 1 per cent. of the copper present. r-smelter therefore had better buy 5 per cent. than 10 per pper pyrites cinders, because in the first case he pays only fifths, while in the latter he must pay for nine-tenths of per present. To compensate for this anomaly, empirical s have been contrived for calculating prices. (W. D.)

TALS. The earliest evidence of a knowledge and metals is found in the prehistoric implements of called Bronze and Iron ages. In the earliest periods tten history, however, we meet with a number of in addition to these two. The Old Testament ns six metals gold, silver, copper, iron, tin, and The Greeks, in addition to these and to bronze, lso to know mercury; and the same set of metals, t additions, forms the list of the Arabian chemists 8th and of the Western chemists of the 13th cen- During the 15th century Basilius Valentinus dis l antimony; he also speaks of zinc and bismuth, eir individuality was established only at a later period 1730-40 the Swede Brand discovered arsenic and (the former is not reckoned a metal by modern ts), while the Englishman Ward recognized the duality of platinum. Nickel was discovered in 1771 onstedt, manganese in 1774 by Scheele. The rs D'Elhujart, in 1783, prepared tungsten; Hjelm, 2, isolated molybdenum from molybdic oxide, where its existence had been conjecturally asserted by Ber in 1781. Uranium, as a new element, was discove Klaproth in 1789; but his metallic "uranium," after been accepted as a metal by all chemists until 18 then recognized as an oxide by Peligot, who subs isolated the true metal. Tellurium was discovered by von Reichenbach in 1782 (again by Klaproth in titanium, by Klaproth in 1795, chromium, by Va in 1797; tantalum, by Hatchett in 1801, and by E in 1802. Palladium, rhodium, iridium, and (which four metals always accompany platinum in i were discovered, the first two by Wollaston in 18 other two by a number of chemists; but their pec was established chiefly by Smithson Tennant.

After Davy, in 1807 and 1808, had recogniz alkalies and alkaline earths as metallic oxides, the ex of metals in all basic earths became a foregone con which was verified sooner or later in all cases. I discovery of aluminium by Wöhler in 1828, and magnesium by Bussy in 1829, claim special m Cadmium, a by no means rare heavy metal, was disc only in 1818, by Stromeyer.

Of the large number of discoveries of rare metals have been made in more recent times only a few mentioned, as marking new departures in research o ing other special points of interest. In 1861 Bunse Kirchhoff, by means of the method of spectrum an which they had worked out shortly before, discover new alkali metals which they called cæsium and rub By means of the same method Crookes, in 1861, disc thallium; Reich and Richter, in 1863, indium, and de Boisbaudran, in 1875, gallium. The existence last named metal had been maintained, theoretica Mendelejeff, as early as 1871. The existence of sca was proved in 1880 by Nelstrom; but what he, a sequently Berzelius, looked upon as the element 1867, proved to be really an oxide by Roscoe, w succeeded in isolating the true metal.

The development of earlier notions on the const of metals and their genetic relation to one anothe the most interesting chapter in the history of ch (see ALCHEMY). What modern science has to say matter is easily stated: all metals properly so call all metals not alloys) are elementary substances; chemically speaking, they are not "constituted" at no two can be related to each other genetically in a whatever. Our scientific instinct shrinks from em this proposition as final; but in the meantime it m accepted as correctly formulating our ignorance subject. All metallic elements agree in this that th each at least one basic oxide, or, what comes to th things, one chloride, stable in opposition to liquid This at once suggests an obvious definition of meta class of substances, but the definition would be artificial and objectionable on principle, because w speak of metals we think, not of their accidental c relations, but of a certain sum of mechanical and p properties which unites them all into one natural What these properties are we shall now endeav explain.

All metals, when exposed in an inert atmo-phe sufficient temperature, assume the form of liquid all present the following characteristic properties. are (at least practically) non transparent, they refle in a peculiar manner, producing what is called "m lustre." When kept in non-metal' els they t shape of a convex meniscus. These liquids, when c to higher temperatures, some sooner others later, p vapours. What these vapours are like is not kn many cases, since, as a rule, they can be produced

[1] For further information on slags, see Berthier, *Traité des essais par sèche*; Winkler, *Erfahrungssätze über die Bildung der en*, Freiberg, 1827; Plattner, *Vorlesungen über allgemeine unde*, i. 28 *sq.*; Percy, *Metallurgy*.

high temperatures, precluding the use of transparent
ls. Silver vapour is blue, potassium vapour is green,
others (mercury vapour, for instance) are colourless.
liquid metals, when cooled down sufficiently, some at
others at higher temperatures, freeze into compact
s, endowed with the (relative) non-transparency and
ustre of their liquids. These frozen metals in general
compact masses consisting of aggregates of crystals
nging to the regular or rhombic or (more rarely) the
dratic system. But in many cases the crystals are so
ly packed as to produce an apparent absence of all
ture. Compared with non-metallic solids, they in
ral are good conductors of heat and of electricity.
their most characteristic, though not perhaps their
general, property is that they combine in themselves
apparently incompatible properties of elasticity and
lity on the one hand and plasticity on the other. To
remarkable combination of properties more than to
hing else the ordinary metals owe their wide applica
in the mechanical arts. In former times a high
ific gravity used to be quoted as one of the characters
e genus; but this no longer holds, since we have come
now of a whole series of metals which float on water.
us now proceed to see to what degree the mechanical
physical properties of the genus are developed in the
ral individual metals.

Non-Transparency. Thus, in the case of even the solid
ls, is perhaps only a very low degree of transparency.
egard to gold this has been proved to be so; gold leaf,
in films of gold produced chemically on glass plates,
smit light with a green colour. On the other hand,
e infinitely thin films of silver which can be produced
nically on glass surfaces are absolutely opaque. Very
films of liquid mercury, according to Melsens, transmit
with a violet-blue colour; also thin films of copper
said to be translucent. Other metals, so far as we
w, have not been more exactly investigated in this
ction.

Colour. Gold is yellow; copper is red; silver, tin, and
others are pure white; the majority exhibit some
ification or other of grey.

Reflexion of Light. Polished metallic surfaces, like
e of other solids, divide any incident ray into two
s, of which one is refracted while the other is reflected,—
a this difference, however, that the former is completely
orbed, and that the latter, in regard to polarization, is
e differently affected.[1] The degree of absorption is
rent for different metals. According to Jamin, the
aining intensity, after one and ten successive perpen-
lar reflexions respectively from the metal-mirrors
ed, is as follows (original intensity = 1):—

	Silver.		Speculum Metal.		Steel.	
	1 R.	10 R.	1 R.	10 R.	1 R.	10 R.
d..	·929	·178	·692	·035	·609	·007
low		·339	·632	·010	·599	·006
olet..		·242	·599	·006	·599	·006

This shows the great superiority of silver as a reflecting
dium, especially in the case of repeated reflexion.

Crystalline Form. Most (perhaps all) metals are capable
rystallization, and in most cases isolated crystals can be
duced by judiciously managed partial freezing. The
tals belong to the following systems: *regular system*
lver, gold, palladium, mercury, copper, iron, lead;
dratic system tin, potassium; *rhombic system* anti-
y, bismuth, tellurium, zinc, magnesium.

Structure. Perhaps all metals, in the shape which they
me in freezing, are crystalline, only the degree of
visibility of the crystalline arrangement is very di
in different metals, and even in the same metal
according to the slowness of solidification and
circumstances.

Of the ordinary metals, antimony, bismuth, an
may be mentioned as exhibiting a very distinct crys
structure: a bar-shaped ingot readily breaks, an
crystal faces are distinctly visible on the fracture
also is crystalline: a thin bar, when bent, "c
audibly from the sliding of the crystal faces ov
another; but the bar is not easily broken, and exhi
apparently non-crystalline fracture.—Class I.

Gold, silver, copper, lead, aluminium, cadmium
(pure), nickel, and cobalt are practically amorpho
crystals (where they exist) being so closely packed
produce a virtually homogeneous mass.—Class II.

The great contrast in apparent structure between
ingots of Class I. and of Class II. appears, however
owing chiefly to the fact that, while the latter crystalliz
regular system, metals of Class I. form rhombic or qu
crystals. Regular crystals expand equally in all dire
rhombic and quadratic ores expand differently in di
directions. Hence, supposing the crystals imme
after their formation to be in absolute contact wi
another all round, then, in the case of Class II., su
tact will be maintained on cooling, while in the
Class I. the contraction along a given straight line
general have different values in any two neighb
crystals, and the crystals consequently become, h
slightly, detached from one another. The cry
structure which exists on both sides becomes visib
in the metals of the first class, and only there ma
itself as brittleness.

Closely related to the structure of metals is their
of "plasticity" (susceptibility of being constrain
new forms without breach of continuity). This t
course includes as special cases the qualities of "
ability" (capability of being flattened out und
hammer) and "ductility" (capability of being dra
wire); but it is well at once to point out that th
special qualities do not always go parallel to each
for this reason amongst others that ductility in a
degree than malleability is determined by the tena
a metal. Hence tin and lead, though very mallea
little ductile. The quality of plasticity is develo
very different degrees in different metals, and even
same species it depends on temperature, and
modified by mechanical or physical operations. A
zinc, for instance, as obtained by casting, is very
but when heated to 100° or 150° C. it becomes suffi
plastic to be rolled into the thinnest sheet or to be
into wire. Such sheet or wire then remains flexib
cooling, the originally only loosely cohering crystals
got intertwisted and forced into absolute contact w
another, an explanation supported by the fact tha
zinc has a somewhat higher specific gravity (7·2) t
original ingot (6·9). The same metal, when hea
205° C., becomes so brittle that it can be powde
mortar. Pure iron, copper, silver, and other met
easily drawn into wire, or rolled into sheet, or fi
under the hammer. But all these operations ren
metals harder, and detract from their plasticity.
original softness can be restored to them by "ann
i.e., by heating them to redness and then quenchi
in cold water. In the case of iron, however, this
only if the metal is perfectly pure. If it contains
parts of carbon per thousand, the annealing process,
of softening the metal, gives it a "temper," me
higher degree of hardness and elasticity (see below

What we have called plasticity must not be m

[1] This may be the cause of the peculiarity of metallic lustre.

e notion of softness, which means the degree of with which the plasticity of a metal can be dis- Thus lead is far softer than silver, and yet the s by far the more plastic of the two. The now experiments of Tresca (*Comptes Rendus*, lix. 754) at the plasticity of certain metals at least goes ably farther than had before been supposed. He d with lead, copper, silver, iron, and some other Round disks made of these substances were in a closely fitting cylindrical cavity drilled in of steel, the cavity having a circular aperture or four centimetres below. By means of an ic press, applied to a superimposed piston, a of 100,000 kilos was made to act upon the disks, e metal was seen to "flow" out of the hole like a quid. In spite of the immense rearrangement of ere was no breach of continuity. What came out was a compact cylinder with a rounded bottom, g of so many layers superimposed upon one Parallel experiments with layers of dough or lus some connecting material proved that the s in all cases moved along the same tracks as e followed by a flowing cylinder of liquid. Of the nown metals potassium and sodium are the softest; n be kneaded between the fingers like wax. After llow first thallium and then lead, the latter being test of the metals used in the arts. Among these ness decreases in about the following order:- lead, ver, pure gold, tin, copper, aluminium, platinum, n. As liquidity might be looked upon as the *ne ra* of softness, this is the right place for stating ile most metals, when heated up to their melting pass pretty abruptly from the solid to the liquid latinum and iron first assume, and throughout a ge of temperatures retain, a condition of viscous idity which enables two pieces of them to be d" together by pressure into one continuous mass. m and sodium might probably be welded if their could be kept clear of oxide.

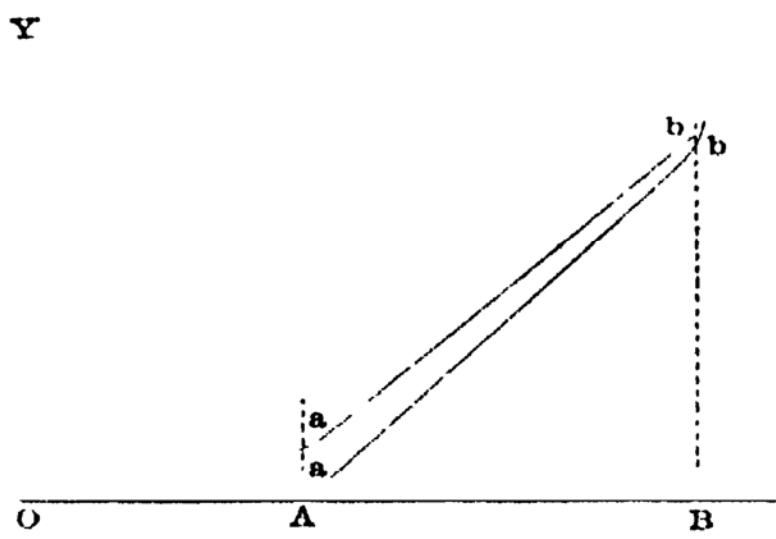
rding to Prechtl, the ordinary metals, in regard to ree of facility or perfection with which they can be red flat on the anvil, rolled out into sheet, or nto wire, form the following descending series:—

Hammering.	*Rolling into Sheet.*	*Drawing into Wire.*
ead.	Gold.	Platinum.
in.	Silver.	Silver.
old.	Copper.	Iron.
ine.	Tin.	Copper.
lver.	Lead	Gold.
opper.	Zinc.	Zinc.
latinum.	Platinum.	Tin.
on.	Iron.	Lead.

an idea of what can be done in this way, it may d that gold can be beaten out to leaf of the thick $\frac{1}{282}$ mm.; and that platinum, by judicious work, drawn into $\frac{1}{2067}$ mm. thick.

he hardness of a metal we mean the resistance t offers to the file or to the engraver's tool. Taking is sense, it does not necessarily measure, *e.g.*, the ce of a metal to abrasion by friction. Thus, for e, 10 per cent. aluminium bronze is scratched by an l made of ordinary steel as used for knife blades. t it has been found that the sets of needles used forating postage stamps last longer if made of um bronze than they do if made of steel.

city.—All metals are elastic to this extent that a change of ought about by stresses not exceeding certain limit values, ppear on the stress being removed. Strains exceeding the f elasticity" result in permanent deformation or (if sufficreat) in rupture. Where this limit lies is in no case prenown. According to Wertheim[1] (who has done more for wledge of the subject than any one else) and Hodgkinson, the real law seems to be pretty much as indicated by the two cur on the accompanying diagram, where, in reference to a metal wire, stretched by an appended weight, the abscissa always me the numerical value P of the weight, the ordinate of the upper cu the total elongation caused by P, the ordinate of the lower curve that part of the elongation which remains when P is removed, so that the piece of the ordinate between the two curves gives the temporary ("elastic") expansion. From P 0 up to a somewhat indefinite point (*a* or A) both curves are nearly straight lines, the lower almost coincidin its beginning with the axis of abscissæ; from that point onwa these two curves approach each other, and at a short distance fi the point of rupture they rapidly converge towards intersection. any value of P which lies fairly on the safe side of A, we have proximately



$$\lambda = \frac{lP}{q},$$

where λ means the elastic (or substantially the total) expansion the length, and q the square section of the wire or cylindrical operated upon. The reciprocal of ϵ (viz. E $1/\epsilon$) is called "modulus of elasticity."

Wertheim has determined this constant for a large number metals and alloys. He used three methods: one was to measure elongations produced, in a wire of given dimensions, by a succes of charges; the other two consisted in causing a measured ba give off a musical note by (*a*) longitudinal and (*b*) transversal vi tion, and counting the vibrations per second. The following t gives some of his results. Column 2 gives the constant E millimetre and kilogramme. Hence 1000/E is the elongation millimetres per metre length per kilo. Column 3 shows the ch causing a permanent elongation of 0·05 mm. per metre,- wh for practical purposes, he takes as giving the limit of elastic column 4 gives the breaking strain. Values of E in sq brackets [ ] are derived from vibration experiments; the from direct measurements of elongations. Numbers in ro brackets ( ) do not necessarily refer to the same specimen as other data.

	For Wt. of 1 Square section, Weight (a Kilos) causing

[2] From Du Brery. [3] Approximate, by H. St Clair Dev

[4] From deflexion of hammered bar of 5 mm. thickness, charged in the mi determined by W. Dittmar.

[5] Composition, $ZnCu_2$ (Wertheim). [6] Composition, $Zn_1Cu_{13}Ni_3$ (Werth

between E and temperature, we quote the results of sch and Loomis, who found the following relations between ulus E_0 for 0° C. and the value E_t for $t°$ C.—

Iron	$E_t = E_0(1$	$.000483\,t$	$.0000001272\,t^2)$
Copper	$E_t = E_0(1$	$.000472\,t$	$.0000000287\,t^2)$
Brass	$E_t = E_0(1$	$.000485\,t$	$.0000001367\,t^2)$

r these three metals at least, the value of E diminishes, emperature increases, at pretty much the same rate per l temperature.

ic Gravity.—This varies in metals from ·594 (lithium) to osmium), and in one and the same specimen is a function erature and of previous physical and mechanical treat It has in general one value for the powdery metal as l by reduction of the oxide in hydrogen below the melting the metal, another for the metal in the state which es spontaneously on freezing, and the latter value again, al, as modified by hammering, rolling, or wire-drawing, &c. echanical operations do not necessarily add to the density; g, it is true, does so necessarily, but rolling or drawing ally causes a diminution of the density. Thus, for , chemically pure iron in the ingot has the specific gravity when it is rolled out into thin sheet, the value falls to n drawn into thin wire, to 7·75 (Berzelius). The follow- gives the specific gravities of all metals (except a few e ones) according to the most trustworthy modern de tions. Where special statements are not made, the numbers assumed to hold for the ordinary temperature (15° to 17° or referred to water of the same temperature (specific gravity n standard, and to hold for the natural frozen metal.

ic Properties.—The specific heats of most metals have been ed very carefully by Regnault. The general result is that, ably with Dulong and Petit's law, the "atomic heats" all very nearly the same value (of about 6·4); *i.e.*, atomic y specific heat ×6·4. Thus we have for silver by theory ·0593, and by experiment ·0570 for 10° to 100° C.

The expansion by heat varies greatly. The following tab the linear expansions from 0° to 100° C. according to Fizeau (*Rendus*, lxviii. 1125), the length at 0° being taken as unit

Name of Metal.	Ex 0°

ely so: gold, (copper).
etically non volatile: (copper), iron, nickel, cobalt, alu- also lithium, barium, strontium, and calcium.
oxyhydrogen flame silver boils, forming a blue vapour, tinum volatilizes slowly, and osmium, though infusible, lily.

Heats of Liquefaction.—Of these we know little. The fol numbers are due to Person—ice, it may be stated, being so

Metal	Latent Heat.	Metal.	Latent Heat
...	2·82	Cadmium ...	13·6
...	5·47	Silver ...	21·1
...	12·4	Zinc ...	28·1

latent heats of vaporization only that of mercury has been ned, by Marignac, who found it to be 103 to 106 units.

ctivity.—Conductivity, whether thermic or electric, is very ly developed in different metals; and, as an exact know these conductivities is of great scientific and practical nce, much attention has been given to their numerical nation. The following are the modes in which the two ivities have been defined as quantities.

ermic. Imagine one side (I) of a metallic plate, D unit be kept at the constant temperature t_1, the other (II) at r a sufficient time each point between I and II will be at nt intermediate temperature, and in every unit of time a quantity Q of heat will pass from any circumscribed area the opposite area S on II, according to the equation

$$Q = k \frac{S(t_1 - t_2)}{D}$$

ed the (internal) conductivity of the metal the plate is . It is, strictly speaking, a function of t_1 and t_2; but given small interval of temperatures it may be taken as a l.

ctric.—When a given constant battery is closed successively ent wires of the same sort, then, according to experience, ngth l of the current (as measured for instance by the heat- nt of the electricity flowing through the circuit in unit of in accordance with the equation

$$A/l = l^2 r/s,$$

is the length and s the square section of the wire, while A stant which, for our purpose, need not be defined in regard hysical meaning; r measures the specific resistance of the ar metal. Supposing a certain silver wire on the one hand ertain copper wire on the other, when substituted for each produce currents of the same strength, we have

$$r_1/s_1 = r_2/s_2,$$

$$r_1/r_2 = s_1/s_2 (= k)$$

is the computed value of the ratio on the right-hand side. taking r_2, the resistance of copper, as unity, we have ., k gives us the specific resistance of silver, that of copper aken = 1. In this relative manner resistances are usually d, silver generally being taken as the standard of compari upposing the relative resistance of a metal to be R, the re- 1/R is called its "electric conductivity." For the same R varies with the temperature, the higher temperature cor- ing to the higher resistance. The following table gives the conductivities of a number of metals as determined by sen, and the relative internal thermic conductivities of ally) the same metals as determined by Wiedemann and with rods about 5 mm. thick, of which one end was kept C., the rest of the rod in a "vacuum" (of 5 mm. tension) '. Matthiesen's results, except in the two cases noted, are s memoir in *Pogg. Ann.*, 1858, cvi. 428

ished in 1860, and declared by Matthiesen to be more exact than the old .

Going by Matthiesen's old numbers, we find them to agree with Wiedemann and Franz's thermic conductivities, which su an obvious and pretty generally received proportion. M sen's new numbers for gold and copper, however, destroy th mony.

Magnetic Properties. Iron, nickel, and cobalt are the metals which are attracted by the magnet and can become m themselves. But in regard to their power of retaining the n netism none of them comes at all up to the compound metal

See MAGNETISM.

Chemical Changes.

The chemical changes which metals are liable to m classified according to the loss of metallicity involv them. We will adopt this principle and begin wit action of metals on metals, which, as experience s always leads to the formation of truly metallic compo

Any two or more metals when mixed together i liquid state unite chemically, or at least molecularly, i case that, although the mixture, on standing (hot) separate into layers, each layer is a homogeneous solut "alloy" of, in general, all the components in one an With binary combinations the following two cases present themselves. (1) the two metals mix perma in any proportion, or (2) either of the two metals r to take up more than a certain limit proportion o other, hence a random mixture of the two metals w general, part into two layers, one a solution of A the other a solution of B in A. The first case pr itself very frequently; it holds, for instance, for gol silver, gold and copper, copper and silver, lead an and any alloy of these two and bismuth. Many cases might be quoted. A good example of the case is lead and zinc, either of which dissolves only small percentage of the other. In the preparation alloy we need not start with the components in the state; the several metals need only be heated toget the same crucible when, in general, the liquid of th readily fusible part dissolves the more refractory ponents at temperatures far below their fusing points. lead, for instance, as many a tyro in chemical analys come to learn to his cost, readily runs through a pla crucible at little more than its own fusing point.

A homogeneous liquid alloy, when solidified sud say by pouring it drop by drop into cold water, nece yields an equally homogeneous solid. But it may so when it is allowed to freeze gradually. If, in thi we allow the process to go a certain way, and then p the still liquid portion, the frozen part generally p itself in the shape of more or less distinct crystals; w this happens or not, the rule is that its composition from that of the mother liquor, and consequently fro of the original alloy. This phenomenon of "liquati it is called, is occasionally utilized in metallurgy f approximate separation of metals from one another;[2] the manipulation of alloys made to be used as such prove very inconvenient. It does so, for instance, case of the copper silver alloy which our coins are of; in a large ingot of such sterling silver the co contain as much as 0·3 per cent. of silver more th outer shell.

The existence of crystallized alloys, as the phen of liquation generally, strongly suggests the ide alloys generally are mixtures, not of their elementar ponents, but of chemical compounds of these element one another, associated possibly with uncombined re of these. This notion is strongly supported by th that the formation of many alloys involves an e evolution of heat and a decided modification in wh would presume to be the properties of the corresp

[2] A good illustration is afforded by the process of Pattinson for concentrating the silver in argentiferous lead. See LEAD.

e. The case of sodium amalgam may be quoted orcible illustration. What goes by this name in ories is an alloy of two to three parts of sodium with ndred parts of mercury, which is easily produced by the two components into contact with each other ns of a mortar and pestle, when they unite, with ation, into an alloy which after cooling assumes the f a grey, hard, brittle solid, although mercury is a and sodium, though a solid, is softer than wax. evidence of chemical action we have in the cases of copper and zinc), bronze (copper and tin), aluminium (copper and aluminium), and in many others that be quoted. There are indeed a good many alloys mation of which is not accompanied by any obvious on of heat or any very marked change in the mean ties of the components. But in the absence of all thermic researche on the subject we are not in a n to assert the absence of chemical action in any Indeed our knowledge of the proximate composition ys is in the highest degree indefinite we do not now of a single composite metal which has been proved to be an unitary compound, and hence the ant problem of the relation in alloys between pro and composition must be attacked on a purely al basis. What has been done in this direction tly summarized in the following paragraphs.

Most metals are white or grey; so are the alloys of tals with one another. Gold alloys generally exhibit some- ke the shade of yellow which one would expect from their tion; its amalgams, however, are all white, not yellow. shows little tendency its characteristic red colour low with white or grey metals. Thus, for instance, the silver to about 30 per cent. of copper exhibits an almost pure olour. The alloys with zinc (brass) or tin (bronze) dish-yellow when the copper predominates largely. As portion of white metal increases, the colour passes succes- into dark yellow, pale yellow, and ultimately into white. um bronze, containing from 5 to 10 per cent. of aluminium, n-yellow.

ility. This quality is most highly developed in certain pure notably in gold, platinum, silver, and copper. Of platinum ittle is known. The other three, on uniting with one substantially retain their plasticities, but the addition of tal outside the group leads to deterioration. Thus, for according to Karsten, copper, by being alloyed with as little er cent. of zinc, loses its capability of being forged at a ; it cracks under the hammer. Antimony or arsenic to nt of 0·15 per cent. renders it unfit for being rolled into thin drawn out into fine wire, and makes it brittle in the heat; cent. of lead prohibits its conversion into leaf.

ss, Elasticity, Tensile Strength.—In reference to these , we shall confine ourselves to some very striking changes for er which the metals (1) gold, (2) silver, (3) copper suffer when with moderate proportions (10 per cent. or so) of (1) cop- copper, (3) tin, zinc, or aluminium respectively. Any of e combinations leads to a considerable increase in the three s named, although these are by no means highly developed lded metals; most strikingly it does so in the case of alumi- ron copper and phosphorus, which is so hard as to be fficult to file, and is said to be equal in tensile strength ght iron. To illustrate this we give in the following table, latthiesen, the breaking strains of double wires, No. 23 in lb avoirdupois, for certain alloys on the one hand and their ents on the other

fic Gravity. This subject has been extensively investigated thiesen, Calvert and Johnson, Kuppfer, and others. In ing the results it is convenient to compare the values (S) with the values (S_0) calculated on the assumption that the of the alloy is equal to the sum of the volumes of the com- Let p_1, p_2, p_3 stand for the relative weights of the com- P for their joint weight, S_1, S_2, S_3 for their specific s, and we have

$$\frac{P}{S_0} = \frac{p_1}{S_1} + \frac{p_2}{S_2} + \dots$$

where the expression on the right hand obviously means joint volume V_0 of the components; but the actual volum alloy formed by their union is, in general, $V = V_0(1 + e)$, means the expansion (or, when negative, the contraction) volume of mixture. Hence the real value

$$S = S_0/(1+e),$$

whence

$$e = (S_0 - S)/S.$$

Matthiesen's investigation (*Pogg. Annalen* for 1860, vol. c extends over a large number of binary alloys derived from th named in the following table. He naturally began by p pure specimens of these metals and determining their gravities. The results (each the mean of a number of de tions) were as follows:—

Name	Specific Gravity S at t° C	t
Antimony	6·713	14·3°
... ...	7·294	12·8
Cadmium.	8·655	10·5
Bismuth	9·823	12·3
	10·168	13·2
Lead	11·376	13·5
Mercury	13·573	11·5
	13·266	12·8

In these, as in all the subsequent determinations for th the weighings were reduced to the vacuum, and the valu referred to water at 4° C. as unity. From eight metals twen different kinds of binary alloys can be produced; of these ight combinations eighteen were selected; in each case the t ponents were fused together in a variety of properly chose proportions, and the specific gravities of these alloys were det The net results are summarized in the following table, w each combination A, B, in the first two columns gives t position in multiples of the "atomic-weights" given in just quoted, while column 3 gives the values of e as calcu the writer from Matthiesen's numbers for S_0 and S. H ample, in the accompanying entries the first line shows union into an alloy of twice 118 parts of tin and once 197 parts of gold involves an expansion from 1 volume into 1·004, the second that the union of once 118 parts of tin with four times 197 parts of gold involves a contraction from 1 volume into 1 – ·028.

ke these numbers trustworthy it would be necessary to de- their probable errors; and this Matthiesen has not done appear that any value of e from 0 to (say) + ·002 counts for and anything up to ·004 certainly must be taken as not much either way. If this is correct, then

o contraction or expansion is proved in the cases S Bi; Cd, Pb; Au, Ag;

contraction (from 0·5 to 4·7 per cent.) is proved for ; Bi, Ag; Bi, Au; Pb, Au; Pb, Bi; Hg, Sn, Hg, Pb; ?); Au, Ag (?);

expansion (from ·5 to 0·8 per cent.) is proved for Sb, Sn; Sn, Cd (?); Sn, Pb (?); certain cases of Sn, Au and Pb, Ag; the two series Sn, Au and Pb, Ag, there are cases both of on and of contraction.

ic and Electric Properties. The specific heat of an alloy, so know, is always in approximate accordance with Dulong t's law. Thus the specific heat of Cu_3Al_2 is

$$\frac{6\cdot4 + 1\cdot0 + 6\cdot4}{5} = \frac{63\cdot5 + 1 + 27}{7},$$

ut the same degree of correctness as the "constant" 6·4 n for itself.

sion.— Matthiesen, from numerous determinations made ys and their components, concludes that the expansion of (from 0° to 100° C.) is nearly equal to the sum of the ex- of its components. Supposing, for instance, one volume of expand (from 0° to t) by α, and one volume of silver by β; alloy of four volumes of gold and three volumes of silver by $(4\alpha + 3\beta)/7$ per unit.

lity. In the case of an alloy the melting point and the point are, in general, separated by a greater or less interval rature, and the latter in itself may have two values as shown berg, who found that when a fused alloy of tin and lead is to freeze the thermometer becomes stationary at two suc- points, as shown in the following table, where x means the of atomic weights of tin united with y of lead in the given the temperatures are in centigrade degrees.

lectric conductivity of alloys *qua* alloys has been investi- Matthiesen. He confined himself to binary alloys derived ertain set of elementary metals. The main results of his researches are given in ELECTRICITY, vol. viii. p. 51. practical electrician it is important to observe how very m conductivity of copper is impaired by very minute admixtu of metals that are good conductors, and also by non meta tamination, especially with oxygen (present as Cu_2O).

Metallic Substances Produced by the Union of Met Small Proportions of Non Metallic Elements.

Hydrogen, as was shown by Graham, is capa uniting with (always very large proportions of) metals, notably with palladium, into metal-like comp But those hydrogen alloys, being devoid of met interest, fall better under the heading PALLADIUM.

Oxygen.— Mercury and copper (perhaps also metals) are capable of dissolving their own oxide formation of alloys. Mercury, by doing so, become and unfit for its ordinary applications. Copper pure to start with, suffers considerable deteriora plasticity. But the presence of moderate proport cuprous oxide has been found to correct the evil i of small contaminations by arsenic, antimony, le other foreign metals. Most commercial coppers ow good qualities to this compensating influence.

Arsenic combines readily with all metals int arsenides, which latter, in general, are soluble in th itself. The presence in a metal of even small prop of arsenide generally leads to considerable deteri in mechanical qualities.

Phosphorus.—The remark just made might be hold for phosphorus were it not for the existence is called "phosphorus bronze," an alloy of coppe phosphorus (*i.e.*, its own phosphide), which possesse able properties. According to Abel, the most fav effect is produced by from 1 to 1½ per cent. of phos Such an alloy can be cast like ordinary bronze, but the latter in hardness, elasticity, toughness, and strength. See PHOSPHORUS.

Carbon.— Most metals when in a molten st capable of dissolving at least small proportions of which, in general, leads to a deterioration in met except in the case of iron, which by the addition o percentages of carbon gains in elasticity and tensile s with little loss of plasticity (see IRON).

Silicon, so far as we know, behaves to metals much like carbon, but our knowledge of facts is What is known as "cast iron" is essentially an iron proper with 2 to 6 per cent. of carbon and less of silicon (see IRON). Alloys of copper and were prepared by Deville in 1863. The alloy with cent. of silicon is white, hard, and brittle. When down to 4·8 per cent., it assumes the colour and fu of bronze, but, unlike it, is tenacious and ductile li

Action of the More Ordinary Chemical Agents Simple Metals.

To avoid repetition, let us state beforehand t metals to be referred to are always understood to b in the compact (frozen) condition, and that, whe series of metals are enumerated as being similarly a the degree of readiness in the action is (so far knowledge goes) indicated by the order in which the members are named, the more readily changed always standing first.

Water, at ordinary or slightly elevated tempe is decomposed more or less readily, with evolu hydrogen gas and formation of a basic hydrate, potassium (formation of KHO), sodium (NaHO), (LiOH), barium, strontium, calcium (BaO_2H_2, &c magnesium, zinc, manganese (MgO_2H_2, &c.).

In the case of group 1 the action is more or less and the hydroxides formed are soluble in water a

y basylous; metals of group 2 are only slowly
d, with formation of relatively feebly basylous
ctically insoluble hydrates. Disregarding the rarer
ts (as we propose to do in this section), the metals
med so far may be said to be proof against the
ot pure water in the absence of free oxygen (air).
he conjoint action of water and air, thallium, lead,
h are oxidized, with formation of more or less
ly soluble hydrates (ThHO, PbO_2H_2, BiO_3H_3),
in the presence of carbonic acid, pass into still less
basic carbonates.
, as everybody knows, when exposed to moisture and
usts,' that is, undergoes gradual conversion into a
ferric hydrate, $Fe_2O_3.nH_2O$; but this process never
place in the absence of air, and it is questionable
er it ever set in in the absence of carbonic acid.
is known that iron never rusts in solutions of
alkalies or lime (which reagents preclude the pre
of free carbonic acid), while it does so readily in
y moist air containing CO_2. When once started
ocess proceeds with increasing rapidity, the ferric
e produced acting as a carrier of oxygen; it gives
t of its oxygen to the adjoining metal, being itself
d to (perhaps) Fe_2O_3, which latter again absorbs
from the air to become ferric hydrate and so on
nann)
per, in the present connexion, is intermediate between
d the following group of metals.
cury, if pure, and all the "noble" metals (silver, gold,
m, and platinum metals), are absolutely proof against
even in the presence of oxygen and carbonic acid.
metals grouped together above under 1 and 2 act
am pretty much as they do on liquid water. Of
st, the following are readily oxidized by steam at a
eat, with formation of hydrogen gas,—zinc, iron,
m, cobalt, nickel, tin. Bismuth is similarly attacked,
owly, at a white heat. Aluminium is barely affected
t a white heat, if it is pure; the ordinary impure
is liable to be very readily oxidized.
ous Sulphuric or Hydrochloric Acid, of course,
dissolve groups 1 and 2, with evolution of hydro
d formation of chlorides or sulphates. The same
for the following group (A):—[manganese, zinc,
-ium] iron, aluminium, cobalt, nickel, cadmium.
ssolves readily in strong hot hydrochloric acid as
, aqueous vitriol does not act on it appreciably in
ld, at 150° it attacks it more or less quickly, accord-
the strength of the acid, with evolution of sul-
ted hydrogen or, when the acid is stronger, of
iron acid gas and deposition of sulphur (Calvert
ohnson). A group (B), comprising copper, are,
ntually, attacked only in the presence of oxygen or
Lead, in sufficiently dilute acid, or in stronger acid if
oo hot, remains unchanged. A group (C) may be
d of mercury, silver, gold, and platinum, which are
uched by either aqueous acid in any circumstances.
(concentrated) oil of vitriol does not attack gold,
um, and platinum-metals generally; all other metals
ding even silver) are converted into sulphates, with
ion of sulphurous acid. In the case of iron, ferric
ate, $Fe_2(SO_4)_3$, is produced: tin yields a somewhat
ite sulphate of its binoxide SnO_2.
ric Acid (*Aqueous*). Gold platinum, iridium, and
um only are proof against the action of this powerful
er. Tin and antimony (also arsenic) are converted by
imately) into hydrates of their highest oxides SnO_2,
(As_2O_5),—the oxides of tin and antimony being
ble in water and in the acid itself. All other metals,
ing palladium, are dissolved as nitrates, the oxidiz-
rt of the reagent being generally reduced to nitric
oxide, NO, or sometimes to N_2O_3 or N_2O_4. Iron
cadmium, also tin under certain conditions, redu
dilute acid, partially at least, to nitrous oxide, N
nitrate of ammonia, $NH_4.NO_3 = N_2O + 2H_2O$.

Aqua Regia, a mixture of nitric and hydrochloric
converts all metals (even gold, the "king of metals," w
the name) into chlorides, except only rhodium, ir
and ruthenium, which, when pure, are not attacked

Caustic Alkalies. Of metals not decomposing
pure water, only a few dissolve in aqueous
potash or soda, with evolution of hydrogen. The
important of these are aluminium and zinc, whi
converted into aluminate, $Al_2O_3.3(K_2$ or $Na_2)O$
zincate, $ZnO.R_2HO$, where R = K or Na respec
But of the rest the majority, when treated with
sufficiently strong alkali, are attacked at least superf
of ordinary metals only gold, platinum, and silv
perfectly proof against the reagents under conside
and these accordingly are used preferably for the co
tion of vessels intended for analytical operations inv
the use of aqueous caustic alkalies. For prep
purposes iron is universally employed and works we
it is not available analytically, because a superficial
tion of the empty part of the vessel (by the water a
cannot be prevented. According to the writer's exp
basins made of pure malleable nickel are free fr
drawback; they work as well as platinum, and rathe
than silver ones do. There is hardly a single meta
holds out against the alkalies themselves when in th
of fiery fusion; even platinum is most violently at
In chemical laboratories fusions with caustic alkal
always effected in vessels made of gold or silver
metals holding out fairly well even in the presence
Gold is the better of the two. Iron, which stands
against aqueous alkalies, is most violently attacked
fused reagents. Yet tons of caustic soda are fuse
in chemical works in iron pots without thereby su
contamination, which seems to show that (clean
like gold and silver, is attacked only by the c
action of fused alkali and air, the influence of the
being of course minimized in large scale operations.

Oxygen or Air. The noble metals (from silver up
do not combine directly with oxygen given as oxyg
(O_2), although, like silver, they may absorb this gas
when in the fused condition, and may not be proof
ozone, O_3. Mercury, within a certain range of te
tures situated close to its boiling point, combines
with oxygen into the red oxide, which, however, br
again at higher temperatures. All other metals
heated in oxygen or air, are converted, more or less
into stable oxides. Potassium, for example, yields pe
K_2O_2 or K_2O_4; sodium gives Na_2O_2; the barium
metals, as well as magnesium, cadmium, zinc, lead,
are converted into their monoxides MeO. Bismu
antimony give (the latter very readily) sesquioxide
and Sb_2O_3, the latter being capable of passin
Sb_2O_4). Aluminium, when pure and kept out of
with siliceous matter, is only oxidized at a whi
and then very slowly, into alumina, Al_2O_3. Tin,
temperatures, passes slowly into binoxide, SnO_2.

Sulphur.—Amongst the better known metals, go
aluminium are the only ones which, when heate
sulphur or in sulphur vapour, remain unchanged.
rest, under these circumstances, are converted into su
The metals of the alkalies and alkaline earth
magnesium, burn in sulphur-vapour as they do in
Of the heavy metals, copper is the one which exh
far the greatest avidity for sulphur, its subsulphi
being the stablest of all heavy metallic sulph
opposition to dry reactions. See METALLURGY

lorine.—All metals, when treated with chlorine gas at proper temperatures, pass into chlorides. In some the chlorine is taken up in two instalments, a lower de being produced first, to pass ultimately into a r chloride. Iron, for instance, is converted first $FeCl_2$, ultimately into Fe_2Cl_6, which practically means ture of the two chlorides, or pure Fe_2Cl_6 as a final ct. Of the several products, the chlorides of gold latinum ($AuCl_3$ and $PtCl_4$) are the only ones which heated beyond their temperature of formation iate into metal and chlorine. The ultimate chlorina product of copper, $CuCl_2$, when heated to redness, poses into the lower chloride, Cu_2Cl_2, and chlorine. e rest, when heated by themselves, volatilize, some er, others at higher temperatures.

the several individual chlorides, the following are s or solids, volatile enough to be distilled from out ss vessels: $AsCl_3$, $SbCl_3$, $SnCl_4$, $BiCl_3$, $HgCl$, the des of arsenic, antimony, tin, bismuth, mercury re vely. The following are readily volatilized in a t of chlorine, at a red heat: Al_2Cl_6, Cr_2Cl_6, Fe_2Cl_6, lorides of aluminium, chromium, iron. The follow hough volatile at higher temperatures, are not vola d at dull redness: KCl, NaCl, LiCl, $NiCl_2$, $CoCl_2$, , $ZnCl_2$, $MgCl_2$, $PbCl_2$, AgCl, the chlorides of sium, sodium, lithium, nickel, cobalt, manganese, magnesium, lead, silver. Somewhat less volatile the last-named group are the chlorides (MCl_2) of m, strontium, and calcium.

tallic chlorides, as a class, are readily . The following are the most important exceptions: oride of silver, AgCl, and subchloride of mercury, l_2, are absolutely insoluble; chloride of lead, $PbCl_2$, subchloride of copper, Cu_2Cl_2, are very sparingly le in water. The chlorides $AsCl_3$, $SbCl_3$, $BiCl_3$, are at decomposed by (liquid) water, with formation of (As_2O_3) or oxychlorides (SbOCl, BiOCl) and hydro- c acid. The chlorides $MgCl_2$, Al_2Cl_6, Cr_2Cl_6, Fe_2Cl_6 a similar decomposition when evaporated with water heat. The same holds in a limited sense for $ZnCl_2$, , $NiCl_2$, and even $CaCl_2$. All chlorides, except those ver and mercury (and, of course, those of gold and um), are oxidized by steam at high temperatures, elimination of hydrochloric acid.

e above statements concerning the volatilities and ilities of metallic chlorides form the basis of a er of important analytical methods for the separation respective metals.

r the characters of metals as chemical elements the r is referred to the article CHEMISTRY and to the l articles on the different metals. (W. D.)

ETAL-WORK. Among the many stages in the de ment of primeval man, none can have been of greater en in his struggle for existence than the discovery e metals, and the means of working them. The s generally given to the three prehistoric periods of life on the earth the Stone, the Bronze, and the Iron imply the vast importance of the progressive steps the flint knife to the bronze celt, and lastly to the edged elastic iron weapon or tool. The length of during which each of these ages lasted must of cours been different in every country and race in the world. Digger Indians of South California have even now rogressed beyond the Stone Age; while some of the of Central Africa are acquainted with the use of r and bronze, though they are unable to smelt or iron.

e metals chiefly used have been gold, silver, copper in (the last two generally mixed, forming an alloy l bronze), iron, and lead. The peculiarities of these various metals have naturally marked out each of th special uses and methods of treatment. The durabil the extraordinary ductility and pliancy of gold, its p being subdivided, drawn out, or flattened into wire of almost infinite fineness, have led to its being u works where great minuteness and delicacy of ex were required; while its beauty and rarity have, most part, limited its use to objects of adornm luxury, as distinct from those of utility. In a degree most of the qualities of gold are shared by and consequently the treatment of these two met always been very similar, though the greater abu of the latter metal has allowed it to be used on a scale and for a greater variety of purposes.

Bronze is an alloy of copper and tin in varying tions, the proportion of tin being from 8 to 20 p The great fluidity of bronze when melted, the slight its contraction on solidifying, together with its dens hardness, make it especially suitable for casting, an of its taking the impress of the mould with extreme ness and delicacy. In the form of plate it can be te and annealed till its elasticity and toughness are increased, and it can then be formed into almost an under the hammer and punch. By other meth treatment, known to the ancient Egyptians, Greek others, but now forgotten, it could be hardened and into knife and razor edges of the utmost keenne many specimens of ancient bronze small quanti silver, lead, and zinc have been found, but their p is probably accidental.

In modern times, after the discovery of zinc, an copper and zinc called brass has been much used, for the sake of its cheapness as compared with bron beauty, durability, and delicacy of surface it is very to bronze, and, though of some commercial importa been of but little use in the production of works of

To some extent copper was used in an almost pu during mediaeval times, especially from the 12th 15th century, mainly for objects of ecclesiastical u as pyxes, monstrances, reliquaries, and croziers, p account of its softness under the tool, and also be was slightly easier to apply enamel and gilding copper than to bronze (see fig. 1). In the m period it was used to some extent in the shape sheeting for roofs, as at St Mark's, Venice; while the 16th and 17th centuries it was largely emplo ornamental domestic vessels of various sorts.

Iron.[1] The abundance in which iron is foun many places, its great strength, its remarkable d and malleability in a red hot state, and the ea which two heated surfaces of iron can be welded t under the hammer combine to make it specially for works on a large scale where strength with l are required things such as screens, window grill mental hinges, and the like.

In its hot plastic state iron can be formed and u under the hammer to almost any degree of refi while its great strength allows it to be beaten leaves and ornaments of almost paper-like thinn delicacy. With repeated hammering, drawing o annealing, it gains much in strength and toughn the addition of a very minute quantity of carbon

[1] Some recent analyses of the iron of prehistoric weap brought to light the interesting fact that many of the specimens of iron manufacture contain a considerable perce nickel. This special alloy does not occur in any known i but is invariably found in meteoric iron. It thus appears was manufactured from meteorolites which had fallen to the an almost pure metallic state, possibly long before prehist had learnt how to dig for and smelt iron in any of the form which are found on the planet.

eel, less tough, but of the keenest hardness. The ployment of cast iron is comparatively modern, in at least only dating from the 16th century: it is ever, incapable of artistic treatment if due regard to the necessities of casting, and if no attempt is imitate the fine-drawn lightness to which wrought eadily lends itself. At the best, however, it is not y suited for the finest work, as the great contrac- ron in passing from the fluid to the solid state the cast somewhat blunt and spiritless.

g the Assyrians, Egyptians, and Greeks the use of her cast or wrought, was very limited, bronze being urite metal for all purposes. culty of smelt ore was prob e reason for well as the rgotten skill nabled bronze empered to a edge. It had, its value, of proof occurs er (*Il.* xxiii.), mass of iron oned as being the prizes at eral games of s.

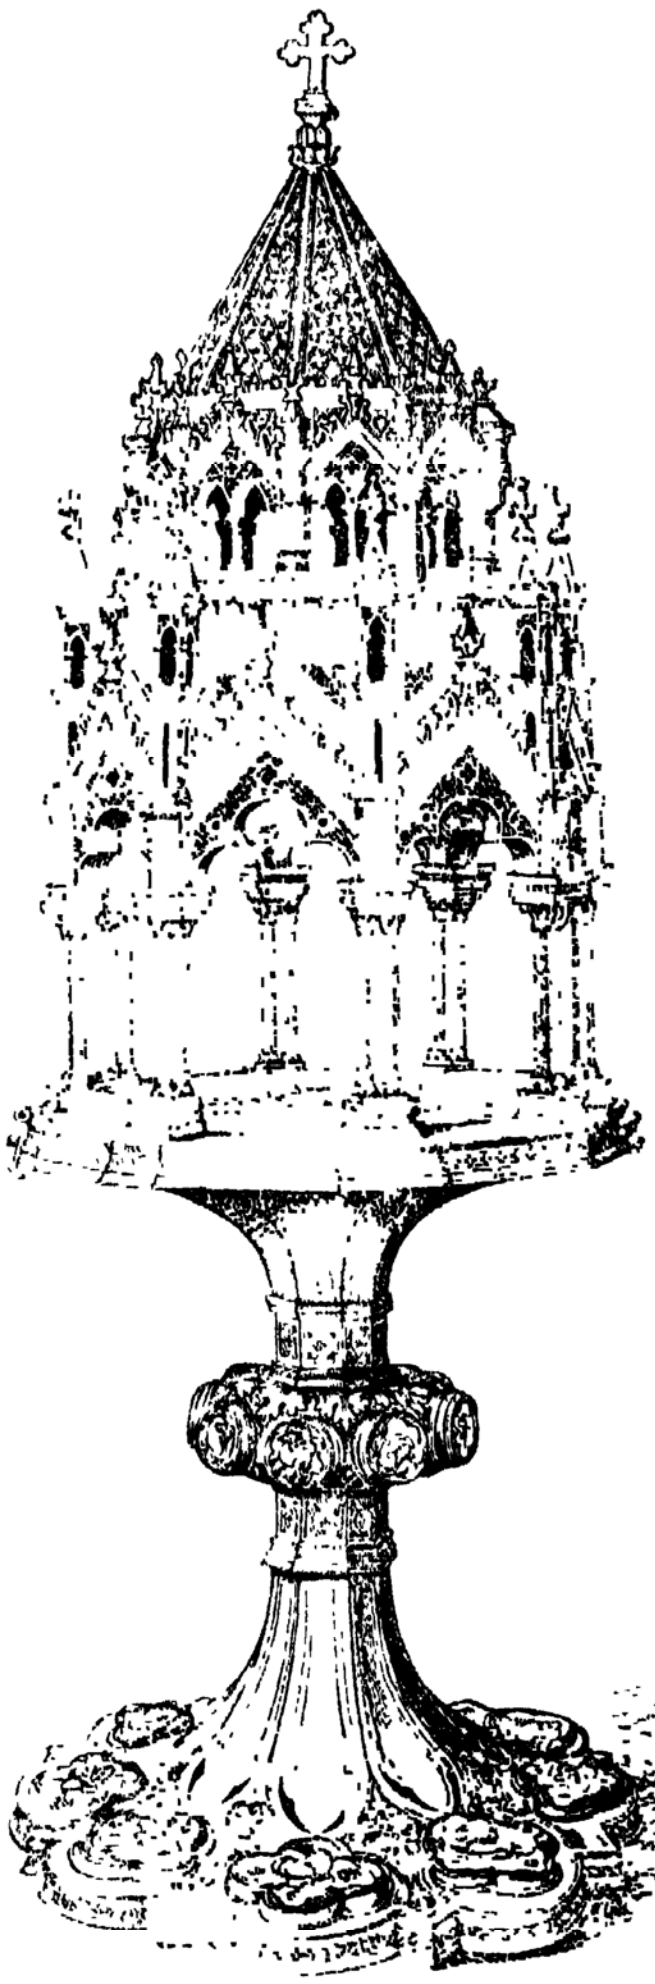

Fig. 1.—Monstrance of Copper Gilt; Italian work of the 15th century

as passed through three stages, the first being ted by solid castings, such as are most celts and mplements of the prehistoric time; the mould rmed of clay, sand, or stone, and the fluid metal ured in till the hollow was full. The next stage the case of bronze, to introduce an iron core, prob- save needless expenditure of the more valuable The British Museum possesses an interesting n or Archaic Italian example of this primitive device. It is a bronze statuette from Sessa on the Volturno, about 2 feet high, of a female standing, robed in a close-fitting chiton. The presence of the iron core has been made visible by the splitting of the figure, owing to the unequal contraction of the two metals. The forearms, which are extended, have been cast separately and soldered or brazed on to the elbows.

The third and last stage in the progress of the art of casting was the employment of a core, generally of clay, round which the metal was cast in a mere skin, only thick enough for strength, without waste of metal. The Greeks and Romans attained to the greatest possible skill in this process. Their exact method is not certainly known, but it appears probable that they were acquainted with the process now called *à cire perdue*—the same as that employed by the great Italian artists in bronze, and still unimproved upon even at the present day. Cellini, the great Florentine artist of the 16th century, has described it fully in his *Trattato della Scultura*. If a statue was to be cast, the figure was first roughly modelled in clay—only rather smaller in all its dimensions than the future bronze; all over this a skin of wax was laid, and worked by the sculptor with modelling tools to the required form and finish. A mixture of pounded brick, clay, and ashes was then ground finely in water to the consistence of cream, and successive coats of this mixture were then applied with a brush, till a second skin was formed all over the wax, fitting closely into every line and depression of the modelling. Soft clay was then carefully laid on to strengthen the mould, in considerable thickness, till the whole statue appeared like a shapeless mass of clay, round which iron hoops were bound to hold it all together. The whole was then thoroughly dried, and placed in a hot oven, which baked the clay, both of the core and the outside mould, and melted the wax, which was allowed to run out from small holes made for the purpose. Thus a hollow was left, corresponding to the skin of wax between the core and the mould, the relative positions of which were preserved by various small rods of bronze, which had previously been driven through from the outer mould to the rough core. The mould was now ready, and melted bronze was poured in till the whole space between the core and the outer mould was full. After slowly cooling, the outer mould was broken away from outside the statue, and the inner core as much as possible broken up and raked out through a hole in the foot or some other part of the statue. The projecting rods of bronze were then cut away, and the whole finished by rubbing down and polishing over any roughnesses or defective places. The most skilful sculptors, however, had but little of this after-touching to do, the final modelling and even polish which they had put upon the wax being faithfully reproduced in the bronze casting.

The further enrichment of the object by enamels and inlay of other metals was practised at a very early period by Assyrian, Egyptian, and Greek metal-workers, as well as by the artists of Persia and mediæval Europe.

The second chief process, that of hammered work (Greek, *sphyrelata*: French, *repoussé*), was probably adopted for bronze work on a large scale, before the art of forming large castings was discovered. In the most primitive method thin plates of bronze were hammered over a wooden core, rudely cut into the required shape, the core serving the double purpose of giving shape to and strengthening the thin metal.

A further development in the art of hammered work consisted in laying the metal plate on a soft and elastic bed of cement made of pitch and pounded brick. The design was then beaten into relief from the back with hammers and punches, the pitch bed yielding to the protuberances which were thus formed, and serving to pre-

he punch from breaking the metal into holes. The was then melted away from the front of the embossed and applied in a similar way to the back, so that the ling could be completed on the face of the relief, al touches being given by the graver. This process hiefly applied by mediæval artists to the precious , but by the Assyrians, Greeks, and other early s it was largely used for bronze.

great gates of Shalmaneser II., 859–824 B.C., from at, now in the British Museum, are a remarkable le of this sort of work on a large scale, though the ent of the reliefs is minute and delicate. The "Siris s," in the same museum, are a most astonishing le of the skill attained by Greek artists in this ssé work (see Brönsted's *Bronzes of Siris*, 1836). are a pair of shoulder-pieces from a suit of bronze r, and each has in very high relief a combat between ek warrior and an Amazon. No work of art in has probably ever surpassed these little figures for , vigour, and expression, while the skill with which ist has beaten these high reliefs out of a flat plate tal appears almost miraculous. The heads of the are nearly detached from the ground, their sub is little thicker than paper, and yet in no place e metal been broken through by the punch. They obably of the school of Praxiteles, and date from the ntury B.C. (see fig. 2).

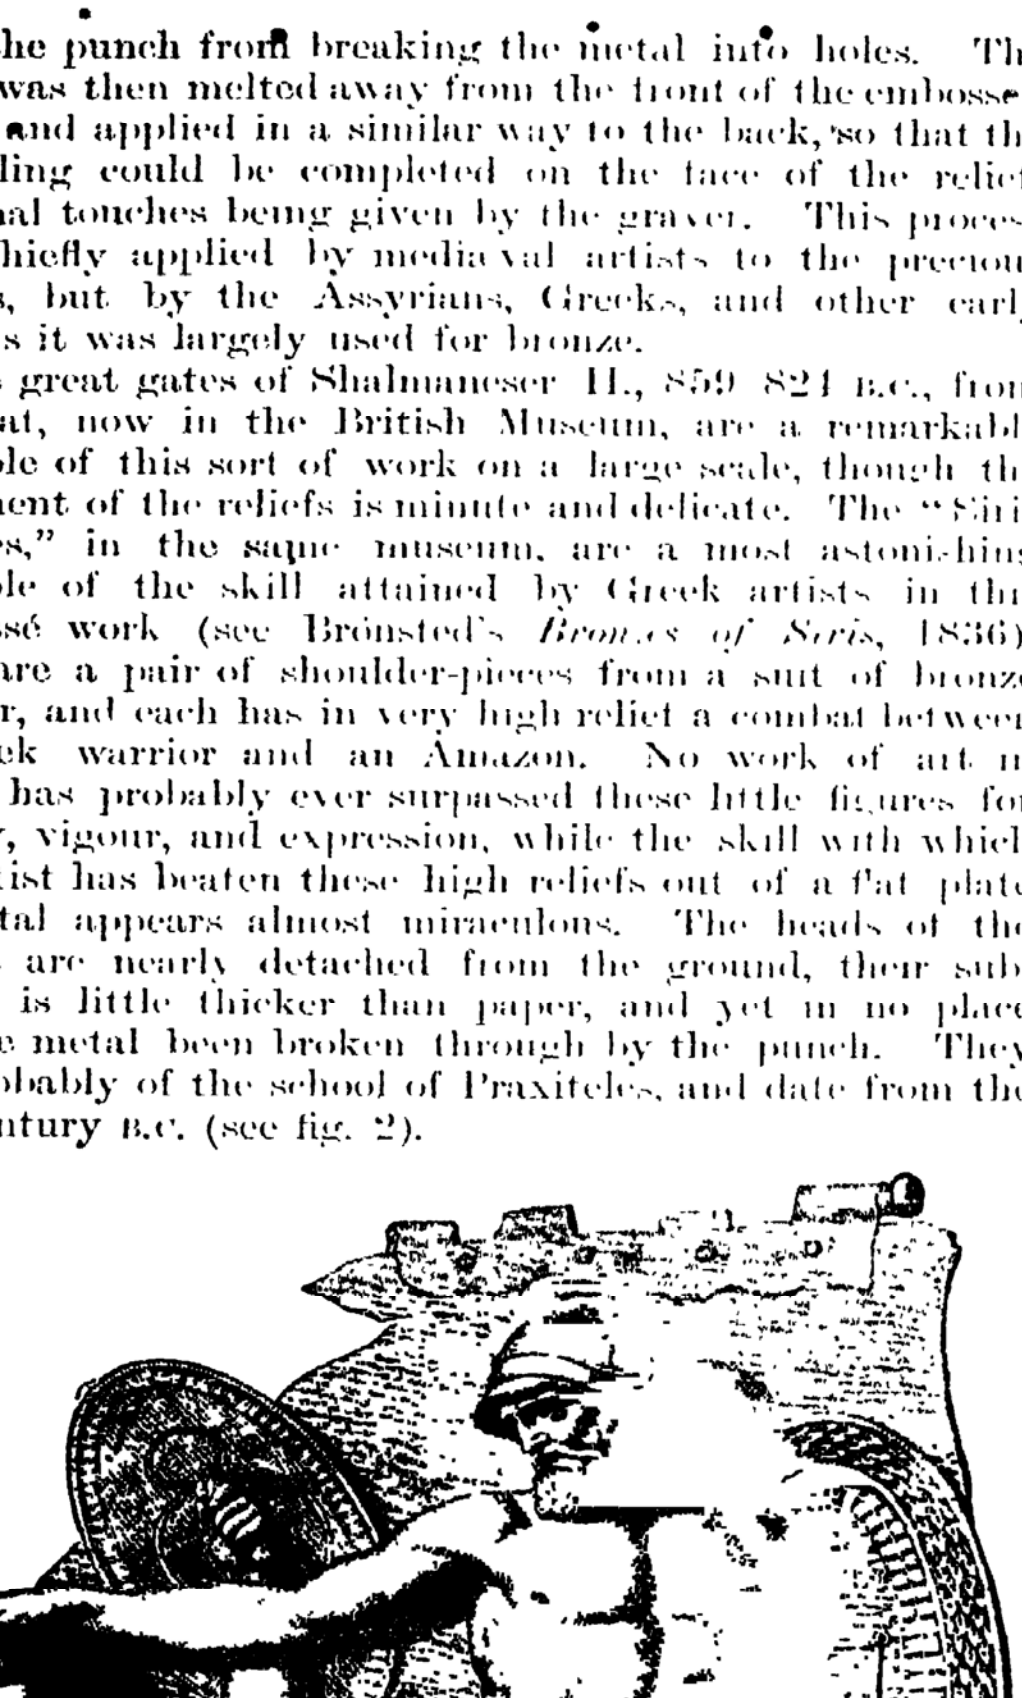

FIG. 2.—One of the Siris Bronzes.

er and tin have been but little used separately. in its pure state may be worked by the same s as bronze, but it is inferior to it in hardness, h, and beauty of surface. Tin is too weak and brittle a metal to be employed alone for any bu objects. Some considerable number of tin drinki and bowls of the Celtic period have been found i wall in the neighbourhood of the celebrated tin and mines, which appear to have been worked from a ve period. The existence of these mines was known Phœnicians, who carried on a considerable trade m with the south west corner of England and the Sci probably the Cassiterides of Pliny and other writers.

The use of lead has been more extended. In sl forms the best of all coverings for roofs and even In the Roman and mediæval periods it was large for coffins, which were often richly ornamented wi work in relief. Though fusible at a very low tempe and very soft, it has great power of resisting deca damp or exposure. Its most important use in an ·en has been in the shape of baptismal fonts, between the 11th and the 14th centuries. The s beauty of colour and durability of old specimens of owing to the natural presence of a small propor silver. Modern smelters carefully extract this silve the lead ore, thereby greatly impairing the durabil beauty of the metal.

As in almost all the arts, the ancient Egyptians e in their metal work, especially in the use of bron the precious metals. These were worked by castin hammering, and ornamented by inlay, gilding, and e with the greatest possible skill.

From Egypt perhaps was derived the early skill Hebrews. Further instruction in the art of metal w came probably to the Jews from the neighbouring c of Tyre. The description of the great gold li Solomon's throne, and the laver of cast bronze sup on figures of oxen, shows that the artificers of that ti overcome the difficulties of metal working and fo on a large scale. The Assyrians were perhaps the remarkable of all ancient nations for the colossal si splendour of their works in metal; whole circuit w great cities, such as Ecbatana, are said to have covered with metal plates, gilt or silvered.

Herodotus, Athenæus, and other Greek and writers have recorded the enormous number of c statues and other works of art for which Babylo Nineveh were so famed. The numerous objects of and other metals brought to light by the excavati the last forty years in the Tigris and Euphrates v though mostly on a small scale, bear witness to the skill and artistic power of the people who produced while the recent discovery of some bronze stat shown by inscriptions on them to be not later than B.C., proves how early was the development of this of art among the people of Assyria.

The Metal-Work of Greece.— The poems of Hom full of descriptions of elaborate works in bronze, iron and silver, which, even when full allowance is ma poetic fancy, show clearly enough a very advanced a of skill in the working and ornamenting of these among the Greeks of his time. His description shield of Achilles, made of bronze, enriched with ba figure reliefs in gold, silver, and tin, could hardly been written by a man who had not some pe acquaintance with works in metal of a very elaborate Again, the accuracy of his descriptions of brazen hou such as that of Alcinous, *Od.* vii. 81—is borne witness Pausanias's mention of the bronze temple of A Χαλκίοικος in Sparta, and the bronze chamber ded to Myron in 618 B.C., as well as by the discovery stains and bronze nails, which show that the whole in of the so-called treasury of Atreus at Mycenæ was

covered with a lining of bronze plates. Of the two chief methods of working bronze, gold, and silver, it is probable that the hammer process was first practised, at least for statues, among the Greeks, who themselves attributed the invention of the art of hollow casting to Theodorus and Rhœcus, both Samian sculptors, about the middle of the 6th century B.C. Pausanias specially mentions that one of the oldest statues he had ever seen was a large figure of Zeus in Sparta, made of hammered bronze plates riveted together. With increased skill in large castings, and the discovery of the use of cores, by which the fluid bronze was poured into a mere skin-like cavity, hammered or repoussé work (Greek, *sphyrelata*) was only used for small objects where lightness was desirable, or for the precious metals in order to avoid large expenditure of metal. The colossal statues of ivory and gold by Phidias were the most notable examples of this use of gold, especially his statue of Athena in the Parthenon, and the one of Zeus at Olympia. The nude parts, such as face and hands, were of ivory, while the armour and drapery were of beaten gold. The comparatively small weight of gold used by Phidias is very remarkable when the great size of the statues is considered.

A graphic representation of the workshop of a Greek sculptor in bronze is given on a fictile vase now in the Berlin Museum (see Gerhard's *Trinkschalen*, plates xii., xiii.). One man is raking out the fire in a high furnace, while another behind is blowing the bellows. Two others are smoothing the surface of a statue with scraping tools, formed like a strigil. A fourth is beating the arm of an unfinished figure, the head of which lies at the workman's feet. Perhaps the most important of early Greek works in cast bronze, both from its size and great historical interest, is the bronze pillar (now in the Hippodrome at Constantinople) which was erected to commemorate the victory of the allied Greek states over the Persians at Platæa in 479 B.C. (see Newton's *Travels in the Levant*). It is in the form of three serpents twisted together, and before the heads were broken off was at least 20 feet high. It is cast hollow, all in one piece, and has the names of the allied states engraved on the lower part of the coils. Its size and the beauty of its surface show great technical skill in the founder's art. On it once stood the gold tripod dedicated to Apollo as a tenth of the spoils. It is described both by Herodotus and Pausanias.

Marble was comparatively but little used by the earlier Greek sculptors, and even Myron, a rather older man than Phidias, seems to have executed nearly all his most important statues in metal.

Additional richness was given to Greek bronze-work by gold or silver inlay on lips, eyes, and borders of the dress; one remarkable statuette in the British Museum has eyes inlaid with diamonds, and fret-work inlay in silver on the border of the chiton.

The mirrors of the Greeks are among the most important specimens of their artistic metal-work. These are bronze disks, one side polished to serve as a reflector, and the back ornamented with engraved outline drawings, often of great beauty (see Gerhard, *Etruskische Spiegel*, 1843–67).

The Greek workman, in fact, was incapable of making an ugly thing. Whatever the metal or whatever the object formed, whether armour, personal ornaments, or domestic vessels, the form was always specially adapted to its use, the ornament natural and graceful, so that the commonest water-jar was a delight alike to him who made it and those who used it.

In metal-work, as in other arts, the Romans were pupils and imitators of the Greeks. Owing to the growth of that spirit of luxury which in time caused the extinction of the Roman empire, a considerable demand arose for magnificent articles of gold and silver plate. The finest examples of these that still exist are the very beautiful silver plate found buried near Hildesheim in 1869, now in the Berlin Museum. They consist of drinking cups, bowls, vases, ladles, and other objects of silver, partly gilt and exquisitely decorated with figures in relief, both chased and repoussé. There are electrotypes of these in the South Kensington Museum.

When the seat of the empire was changed from Rome to Byzantium, the latter city became the chief centre for the production of artistic metal-work. From Byzantium the special skill in this art was transmitted in the 9th and 10th centuries to the Rhenish provinces of Germany, and thence to Italy, and thence to the whole of Western Europe. In this way the 18th-century smith who wrought the famous Versailles Court iron gates was the heir to the mechanical skill of the ancient metal-workers of Phœnicia and Greece.

In that period of extreme degradation into which the higher arts fell after the destruction of the Roman empire, though true feeling for beauty and knowledge of the subtleties of the human form remained for centuries dormant, yet at Byzantium at least there still existed great technical skill and power in the production of all sorts of metal-work. In the age of Justinian (first half of the 6th century) the great church of St Sophia at Constantinople was adorned with an almost incredible amount of wealth and splendour in the form of gold altars, candlesticks, and other ecclesiastical furniture of massive gold and silver.

Metal-Work in Italy.—It was therefore to Byzantium that Italy turned for metal workers, and especially for smiths, when, in the 6th to the 8th centuries, the great church of St Peter's in Rome was enriched with masses of gold and silver for decorations and fittings, the gifts of successive donors from Belisarius to Leo III., the mere catalogue of which reads like a tale from the *Arabian Nights*. The gorgeous Pala d'Oro, still in St Mark's at Venice, a magnificent retable covered with delicate reliefs and enriched with fine enamels and jewels, was the work of Byzantine artists during the 11th century. This work was in progress for more than a hundred years, and was set in its present form in 1106 A.D., though still unfinished (see Bellomo, *Pala d'Oro di S. Marco*, 1847).

It was, however, especially for the production of bronze doors for churches, ornamented with panels of figures in high relief, that Italy obtained the services of Byzantine workmen (see Garrucci, *Arte Cristiana*, 1872–82). An artist named Staurachios produced many works of this class, some of which still exist, such as the bronze doors of the cathedral at Amalfi, dated 1066 A.D. Those by the same artist, though his name was spelt differently, were the bronze doors of San Paolo fuori le Mura, Rome, careful drawings of which exist, though the originals were destroyed in the fire of 1824. Other important examples exist at Ravello (1197), Monreale (1099), Amalfi (1062), Atrani (1087); and doors of Monreale in Sicily and at Trani, signed by an artist named Barisanos (end of the 12th century); the reliefs of the last are remarkable for expression and dignity, in spite of their early rudeness of modelling and ignorance of the human figure.

Most of these works in bronze were enriched with lines inlaid in silver, and in some cases with a black niello or enamel. The technical skill of these Byzantine metal-workers was soon acquired by native Italians, who produced many important works in bronze similar in style and execution to those of the Byzantines. Such, for example, are the bronze doors of San Zeno at Verona (unlike the others, of repoussé not cast work) and of the Duomo of Pisa, cast in 1180 by Bonannus, and

of Troia, the last made in the beginning of the 12th by Oderisius of Benevento. Another artist named f Amalfi worked in the same way; and in the 9 the brothers Hubertus and Petrus of Piacenza bronze door for one of the side chapels in San i in Laterano. One of the most important early ns of metal-work is the gold and silver altar of mbrogio in Milan. In character of work and it resembles the Venice Pala d'Oro, but is still n date, being a gift to the church from Arch- Angilbert II. in 835 A.D. (see Du Sommerard, Agincourt, *Moyen Âge*). It is signed WOLVINIVS R PHABER; nothing is known of the artist, but he y belonged to the semi Byzantine school of the rovinces; according to Dr Rock he was an Anglo- oldsmith. It is a very sumptuous work, the front altar being entirely of gold, with repoussé reliefs soudée enamels; the back and ends are of silver, ld ornaments. On the front are figures of Christ twelves apostles; the ends and back have reliefs ing the life of St Ambrose.

most important existing work of art in metal of the ntury is the great candelabrum now in Milan al. It is of gilt bronze, more than 14 feet high; seven branches for candles, and its upright stem orted on four winged dragons. For delicate and execution, together with refined gracefulness of it is unsurpassed by any similar work of art. Every the numerous little figures with which it is adorned ry of study for the beauty and expression of the face, dignified arrangement of the drapery (see fig. 3).

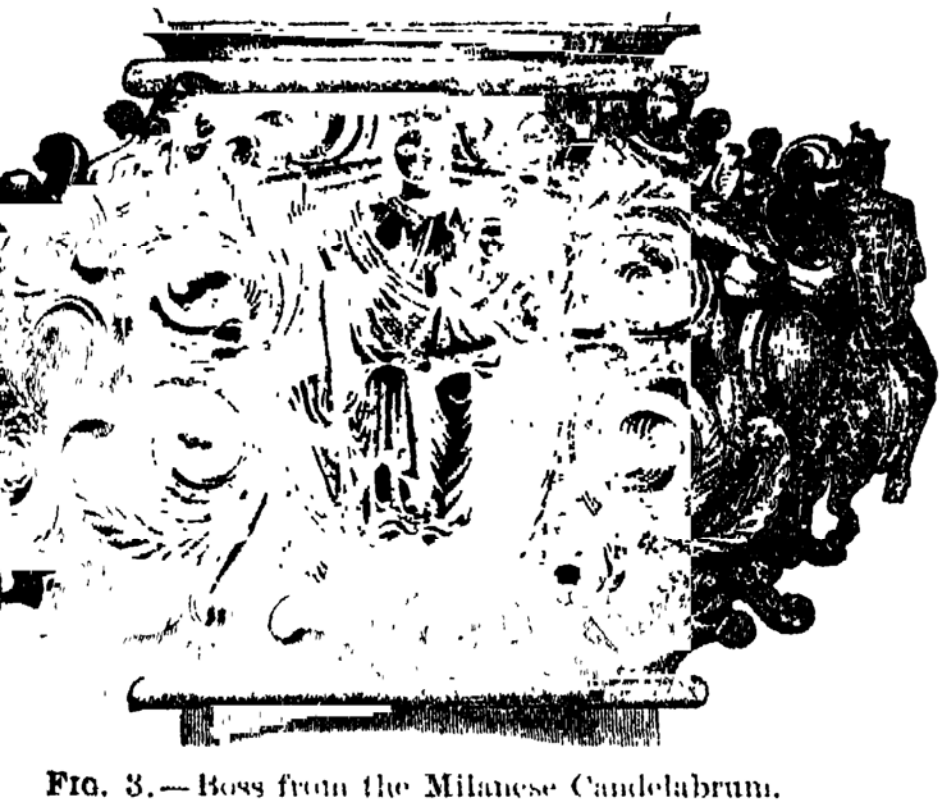

FIG. 3.—Boss from the Milanese Candelabrum.

mi-conventional open scroll-work of branches and hich wind around and frame each figure or group is with the most perfect taste and richness of fancy, ach minute part of this great piece of metal-work hed with all the care that could have been bestowed smallest article of gold jewellery. Though some- in the grotesque dragons of the base recalls the ine school, yet the beauty of the figures and the eling for graceful curves and folds in the drapery o a native Italian as being the artist who produced onderful work of art. There is a cast in the South gton Museum.

ing the 13th and 14th centuries in Italy the wide- influence of Niccolo Pisano and his school encouraged lptor to use marble rather than bronze for his work. s period wrought iron came into general use in the f screens for chapels and tombs, and grills for ws. These are mostly of great beauty, and show table skill in the use of the hammer, as well as power in adapting the design to the requirements of the material. Among the finest examples of this sort of work are the screens round the tombs of the Scala family at Verona, 1350 75, - a sort of net work of light cusped quatrefoils, each filled up with a small ladder (scala) in allusion to the name of the family. The most elaborate specimen of this wrought work is the screen to the Rinuccini chapel in Santa Croce, Florence, of 1371, in which moulded pillars and window like tracery have been wrought and modelled by the hammer with extraordinary skill (see Wyatt, *Metal-Work of Middle Ages*). Of about the same date are the almost equally magnificent screens in Sta Trinita, Florence, and at Siena across the chapel in the Palazzo Pubblico. The main part of most of these screens is filled in with quatre-foils, and at the top is an open frieze formed of plate iron pierced, repoussé, and enriched with engraving.

In the 14th century great quantities of objects for ecclesiastical use were produced in Italy, some on a large scale, and mostly the works of the best artists of the time.

FIG. 4.—Silver Reliefs from the Pistoia Retable.

The silver altar of the Florence baptistery is one chief of these; it was begun in the first half of the 14th century, and not completed till after 1477 (see *Gaz. des Beaux Arts*, Jan. 1883). A whole series of the greatest artists in metal laboured on it in succession, among whom were Orcagna, Ghiberti, Verrocchio, Ant. Pollajuolo, and many others. It has elaborate reliefs in repousse work, cast canopies, and minute statuettes, with the further enrichment of translucent coloured enamels. The silver altar and retable of Pistoia cathedral (see fig. 4), and the great shrine at Orvieto, are works of the same class, and of equal importance.

Whole volumes might be devoted to the magnificent works in bronze produced by the Florentine artists of this century, works such as the baptistery gates by Ghiberti, and the statues of Verrocchio, Donatello, and many others, but these come rather under the head of sculpture.

very magnificent bronze screens were produced at
ne, especially that in Prato cathedral by Simone,
of Donatello, in 1444-61, and the screen and bronze
nts of the tomb of Piero and Giovanni dei Medici
Lorenzo, Florence, by Verrocchio, in 1472
he latter part of the 15th century and the beginning
16th the Pollajuoli, Ricci, and other artists devoted
labour and artistic skill to the production of candle-
and smaller objects of bronze, such as door knockers,
ot which are works of the greatest beauty. The
sticks in the Certosa near Pavia, and in the cathedrals
ice and Padua, are the finest examples of these.
olò Grossi, who worked in wrought iron under the
gge of Lorenzo dei Medici, produced some wonderful
ens of metal work, such as the candle-sticks, lanterns,
gs fixed at intervals round the outside of the great
(see fig. 5). The Strozzi palace in Florence and

Florentine work.

lazzo del Magnifico at Siena have fine specimens of
the former of wrought iron, the latter in cast bronze.
Venice fine work in metal, such as salvers and vases,
ing produced, of almost Oriental design, and in
ases the work of resident Arab artificers. In the
entury Benvenuto Cellini was supreme for skill in
duction of enamelled jewellery, plate, and even larger
of sculpture (see Plon's *Ben. Cellini*, 1882), and John
gna in the latter part of the same century inherited
extent the skill and artistic power of the great
ntury artists. Since that time Italy, like other
es, has produced little metal-work of real value.
n.—From a very early period the metal-workers of
ave been distinguished for their skill, especially in
of the precious metals. A very remarkable set of
ens of goldsmith's work of the 7th century are the
votive crowns, two crosses, and other objects found
in 1858 at Guarrazar, and now preserved at Madrid
Paris in the Cluny Museum (see Du Sommerard, *L*
Cluny, 1852). Magnificent works in silver, such as
altar crosses, and church vessels of all kinds, we
duced in Spain from the 11th to the 16th cen
especially a number of sumptuous tabernacles (*c*
for the host, magnificent examples of which stil
in the cathedrals of Toledo and Seville. The
and wrought iron screens *rejas*, mostly of th
and 16th centuries to be found in almost eve
portant church in Spain are very fine examples of
work. They generally have moulded rails or bal
and rich friezes of pierced and repoussé work, the
being often thickly plated with silver. The comm
of metal for pulpits is a peculiarity of Spain; t
sometimes of bronze, as the pairs in Burgos and
cathedrals, or in wrought iron, like those at Zam
in the church of San Gil, Burgos. The great candl
or *tenebrarium* in Seville cathedral is the finest
men of 16th century metal work in Spain; it was
the work of Bart. Morel in 1562. It is of cast
enriched with delicate scroll-work foliage, and wit
bers of well modelled statuettes, the general effec
very rich and graceful. Especially in the art of
work Spain was much influenced in the 15th an
centuries by both Italy and Germany, so that num
Spanish objects produced at that time owe little or
to native designers. At an earlier period Arab and
ish influence is no less apparent.

England. In Saxon times the English metal-w
especially of the precious metals, possessed great sk
appear to have produced shrines, altar-frontals, r
and other ecclesiastical furniture of considerable s
magnificence.

Dunstan, archbishop of Canterbury (925 98
Bernward, bishop of Hildesheim a few years later,
Eloi of France three centuries earlier, was himself a
worker in all kinds of metal. The description of t
and silver retable given to the high altar of Ely by
Theodwin in the 11th century, shows it to have been
and elaborate piece of work decorated with many
and figures in the round. In 1241 Henry III. g

14th century.

More mechanical in execution, though still very
effect, is that sort of iron tracery work produced by
out patterns in plate, and superimposing one pla
the other, so as to give richness of effect by the s
produced by these varying planes. The screen by
V.'s tomb at Westminster is a good early specimen
kind of work.

The screen to Bishop West's chapel at Ely, a
round Edward IV.'s tomb at Windsor, both made t
the end of the 15th century, are the most mag

sh examples of wrought iron, in which every art and
f skill known to the smith has been brought into
o give variety and richness to the work.
ch wrought-iron work of great beauty was produced
beginning of the 18th century, especially under the
ntendence of Sir Christopher Wren (see Elbetts,
Work of 17th and 18th Centuries, 1880). Large
g leaves of acanthus and other plants were beaten
vith wonderful spirit and beauty of curve. The
from Hampton Court are the finest examples of
ass of work (see fig. 7).
m an early period bronze and latten (a variety of
were much used in England for the smaller objects
of ecclesiastical and domestic use, but except for
and lecterns were but little used on a large scale till
5th century. The full length recumbent effigies of
III. and Queen Eleanor at Westminster, cast in
by the "cire perdue" process, and thickly gilt, are
if not superior, in artistic beauty to any sculptor's
of the same period (end of the 13th century) that was
ced in Italy or elsewhere. These effigies are the work

METAMORPHOSIS. This term has been em in several distinct senses in biology. During th part of the century it was constantly used to incl current morphological conceptions, as, for instance, parts of a flower as modified or "metamorphosed" or of the segments of a skull as modified ve It is still frequently employed to denote that prog change from the general to the special undergone developing tissues and organs (see BIOLOGY, EMBRY but in this sense is conveniently superseded by th "differentiation." In the process of animal develo two types are broadly distinguishable,—a foetal t which development takes place wholly or in great either within the egg or within the body of the and a larval type, in which the young are born condition more or less differing from that of the while the adult stage again is reached in one of two either by a process of gradual change, or by a suc of more or less rapid and striking transformatio which the term metamorphosis is now usually res Metamorphosis is generally regarded as havin brought about by the action of natural selection, pa curtailing and reducing the phases of developme obvious advantage in economy of both structur functional change), and partly also in favouri acquirement of such secondary characters as are tageous in the struggle for existence. Freshwa terrestrial animals develop without metamorphosis more frequently than marine members of the same a circumstance which has been variously explained details of metamorphoses see the articles on the groups of animals; see also Balfour's *Comparati bryology*, 1880–81.

M E T A P H Y S I C

E term metaphysic, originally intended to mark the place of a particular treatise in the collection of otle's works, has, mainly owing to a misunderstanding, ved several other titles, such as "First Philosophy," ology," and "Theology," which Aristotle himself or suggested. Neo-Platonic mystics interpreted it gnifying that which is not merely "after" but ond" physics, and found in it a fit designation science which, as they held, could not be attained t by one who had turned his back upon the natural . And writers of a different tendency in a later gladly accepted it as a convenient nickname for ies which they regarded as having no basis in ience, in the same spirit in which the great German ter Stein used the analogous title of "metapolitics" ry and unpractical schemes of social reform. A brief ation of the contents of Aristotle's treatise may enable give a general definition of the science which was first ctly constituted by it, and to determine in what sense bjects which that science has to consider are beyond e and experience.

r Aristotle, metaphysic is the science which has to do Being as such, Being in general, as distinguished from special sciences which deal with special forms of . There are certain questions which, in Aristotle's we have a right to ask in regard to everything that presents itself as real. We may ask what is it nature or definition, and what are the conditions realization; we may ask by what or whom it was pr and for what end; we may ask, in other words, formal and the material, for the efficient and th causes of everything that is. These different qu point to different elements in our notion of Being, e which may be considered in their general relation from any particular case of their union. These, th the first philosophy must investigate. But, furth science of being cannot be entirely separated fr science of knowing, but must determine at least i general principles. For the science that deals wit is most universal in being is, for that very reason, with the objects which are most nearly akin intelligence. These, indeed, are not the objects wh first presented to our minds; we begin with the par not the universal, with a *πρῶτον ἡμῖν* which is not *φύσει*; but science reaches its true form only wh order of thought is made one with the order of natu the particular is known through the universal. V conversion or revolution of the intellectual point o is not to be regarded as an absolute change from e truth; for Aristotle holds that *nihil est in intellec non prius in sensu*, in the meaning that in sense per there is already the working of that discriminative

which, beginning in sense perception, with the dis- of particular from particular, can rest only when it prehended things in their universal forms or defini Looking at knowledge *formally*, the highest law of , the law of contradiction (or, as we might call it, to Aristotle's meaning more exactly, the law of de- or distinction), is already implied in the first act of ion by which one thing is distinguished from another. g at it *materially*, the reason of man is to be con- as potentially all that is knowable; *i.e.*, objects are ed to it that for it to know them in their essential ons is only to know itself. The aim of science, in ew, is to break through the husk of matter, and to nd things in their forms, in which they are one with d that knows them. Hence also it follows that in o the most universal science, the science of Being in , the mind is not leaving the region of immediate nce, in which it is at home, for a far-off region of tions. Rather it is returning to itself, apprehend t which is most closely related to itself, and which re, though it is late in being made the direct object stigation, is yet presupposed in all that is, and is ?

aphysic, then, is the science which deals with the les which are presupposed in all being and knowing, they are brought to light only by philosophy. r trait completes the Aristotelian account of it. eology, or the science of God. Now God is *νόησις* s, pure self consciousness, the absolute thought which with its object, and He is therefore the first cause xistence. For, while the world of nature is a world ion and change, in which form is realized in matter, ocess of the finite can be explained only by referring to an unmoved mover, in whom there is no distinc matter and form, and who is, therefore, in Aristotle's to be conceived as pure form, the purely ideal or e activity of a consciousness whose object is itself. conception, however, while it secures the independ d absoluteness of the unmoved mover, by removing m all relation to what is other than himself, seems e his connexion with the world inexplicable. We this theory refer the world to God, but not God to rld. Hence Aristotle seems sometimes to say that the first mover only as He is the last end after which ation strives, and this leads him to attribute to a desire or will which is directed towards the good bject or end.

totle then brings together in his metaphysic three ts which are often separated from each other, and nnexion of which is far from being at once obvious o him the science of the first principles of being. lso the science of the first principles of knowing. , it is the science of God, as the beginning and end things, the absolute unity of being and thought, in all the differences of finite thought and existence her excluded or overcome.

some this description of the contents of Aristotle's e, and especially the last part of it, may seem to be irmation of all the worst charges brought against hysic. For at both extremes this supposed science to deal with that which is beyond experience, and therefore cannot be verified by it. It takes us o a beginning which is prior to the existence as well he consciousness of finite objects in time and space, n to an end to which no scientific prophecy based our consciousness of such objects can reach. In the former aspect of it, it has to do with notions so ab and general that it seems as if they could not be fix tested by reference to any experience, but must neces be the playthings of dialectical sophistry. In the aspect of it, it entangles us in questions as to the cause and ultimate meaning of things, questions inv so comprehensive a view of the infinite universe in we are insignificant parts that it seems as if any at to answer them must be for us vain and presump On both sides, therefore, metaphysic appears to attempt to occupy regions which are beyond the hal space of the intelligible world to deal with ideas are either so vague and abstract that they cann fastened to any definite meaning, or so complex an reaching that they can never by any possibility be ve For beings like men, fixed within these narrow lim space and time, the true course, it would seem, "cultivate their gardens," asking neither whence come nor whither they go, or asking it only with possible limits of history and scientific prophecy. back to the beginning or on to the end is beyond even in a temporal, still more in a metaphysical, That which is *πρώτον φύσει* escapes us even more abso than the prehistorical and pregeological records o and his world. That which is *ἔσχατον φύσει* esca even more absolutely than the far off future ty civilization, which social science vainly endeavor anticipate. Our state is best pictured by that Anglican philosopher who compared it to a bird through a lighted room "between the night an night." The true aim of philosophy is, therefo would seem, to direct our thoughts to the careful ination and utilization of the narrow space allotted by an inscrutable power, and with scientific self-re to refrain from all speculation either on first or o causes.

The main questions as to the possibility and the na metaphysic, according to Aristotle's conception of i be summed up under two heads. We may ask w we can in any sense reach that which is beyond expe and, if so, whether this "beyond" is a first or principle, a pre-condition or a final cause of natu experience, or both. The former question branch into two, according as we look at metaphysic fr objective or the subjective side, or, to express the more accurately, according as we consider it in rela those natural objects which are *merely* objects of know or in relation to those spiritual objects which a subjects of knowledge. We shall therefore consider physic, first, in relation to science in general, and, se in relation to the special science of psychology. latter question also has two aspects; for, while the a first cause or principle points to the connexion b metaphysic and logic, the idea of a last principle cause connects metaphysic with theology. We shall fore consider in the third place the relation of meta to logic, and in the fourth place its relation to religi the philosophy of religion.

1. *The Relation of Metaphysic to Science.* — The begi of science and metaphysic are identical, though the sense in which it may be admitted that the metap comes before the scientific or positive era. The first of philosophy grasp at once at the prize of a knowledge. No sooner did the Greeks become diss with the pictorial synthesis of mythology by whic thoughts were first lifted above the confusion of par things, than they asked for one universal principle should explain all things. The Ionic school sought some one phenomenon of nature which might be the key to all other phenomena. The Eleatics, see

ναὶ κριτική, Anal. Post., II. 99*b*.

hat is said here as to the intelligence is partly taken from the *ora*. The necessary qualifications of the above general state- Aristotle's views will be given subsequently.

of making one finite thing the explanation of all
nite things, tried to find that explanation in the very
of unity or being itself. We need not underestimate
culative value of such bold attempts to sum up all
iety of the world in one idea, but it is obvious that
ther give a name to the problem than solve it, or
y put the very consciousness of the problem in place
solution of it. Science is possible only if we can
m the particular to the universal, from a subjective
things as they immediately present themselves to
perception to an objective determination of them
laws and principles which have no special relation
particular set of events or to any one individual
But this is only one aspect of the matter. To
from a conception of the world *in ordine ad*
num to one *in ordine ad universum*, and so to
t and eliminate what is merely subjective and
tal in our first consciousness of the world, is the
ng of knowledge. But little is gained until the
al, which we reach through the negation the
lars, is more than their mere negation, unless it
v or principle by means of which we can explain
rticulars. Now the defect of early philosophy
t its universal was "the one beyond the many,"
"one in the many," in other words, that it was
aw or principle by which the particulars subsumed
it could be explained, but simply the abstraction
element common to them. But the process of
dge is a process that involves both analysis and
is, negation and reaffirmation of the particulars
hich we start. If we exaggerate the former aspect
e enter upon the *via negativa* of the mystics, the
pure abstraction and negation, which would open
nd to the ideal reality of things simply by shutting
the perceptions of sensible phenomena. And, if we
out this method to its legitimate result, we must
ne highest abstraction, the abstraction of Being, as if
the sum of all reality, and the Neo-Platonic ecstasy
h all distinction, even the distinction of subject and
is lost as the only attitude of mind in which truth
apprehended.

ne philosophy of the Socratic school we find the first
t at a *systematic* as opposed to an *abstract* theory
t attempt to bring together the one and the many,
to determine the former that it should throw light
ne latter. Yet even in Plato the tendency to oppose
niversal to the particular is stronger than the
gy to relate them to each other, and in some of his
ues, as, *e.g.*, in the *Phædo*, we find a near approach
identification of the process of knowledge with
tion which is the characteristic of mysticism.
le, therefore, had some ground for taking the Platonic
le that "the real is the universal" in a sense which
s the reality of the individual. Yet, though he
d Plato's error in opposing the universal to the
lar, and though, at the same time, he did not
y lose sight of the truth which Plato had exagger
hat the particular is intelligible only *through* the
sal, Aristotle was not able to escape the influence
dualism which had marred the philosophy of his
essor. Hence the effect of his protest against a
phy of abstraction was partly neutralized by his
tion between the divine Being as pure form and
as the unity of form and matter, and again by his
tion of the pure reason which apprehends the
of things from the perceptions of sense which deal
orms realized in matter. And after Aristotle's time
ndency of philosophy was more and more to withdraw
contact with experience. The Neo-Platonic philo-
and the Christian theology which was so strongly
influenced by it, contained, indeed, an idea of the
ciliation of God and nature, and hence of form and
which must ultimately be fatal to dualism, and there
the method of mere abstraction. But the explicit m
of the philosophy of the Middle Ages was still du
and the mode in which the Aristotelian formula
wrought into the substance of Christian doctrine
scholastics tended more and more to conceal that
the unity of opposites which was involved in Christ
Hence mediæval realism presented, in its most ou
form, the doctrine that "the real is the universal," n
by the universal nothing more than the abstract.
a natural consequence, the modern insurrection
scientific spirit against scholasticism took its star
an equally bald and one-sided assertion of the o
principle, that "the real is the individual," mean
that the individual of immediate perception. It Pla
had dwelt too exclusively on one aspect of the pro
knowledge, viz., that it seeks to rise above the particu
sensible, the subjective, to the universal, the intelligi
objective, as if in the latter alone were reality to be
modern men of science learnt from their first nomi
teachers to regard the universal as nothing more t
abbreviated expression for the particulars, and scienc
as a mere generalization of the facts of sensible perc
But this view of scientific knowledge, as a mere re
tion of what is immediately given in sense, is as im
as the opposite theory, which reduces it to the
negation of what is so given. An ideal world
and entirely divorced from the phenomenal, and a
world which is simply a repetition of the phenc
are equally meaningless. The processes of scienc
both a negative and a positive side; they involve
tion of the particular as it is immediately presen
sense, but only with a view to its being reaffirmed
new determination through the universal. The fa
is first presented to us is not the fact as it is; for,
it is from the fact as given that we rise to the kno
of the law, it is the law that first enables us to und
what the fact really means. Our first conscious
things is thus, not an immovable foundation upon
science may build, but rather a hypothetical and s
tradictory starting-point of investigation which
changed and transformed as we advance.

The nominalism of scientific men in modern time
to two special causes, one of which has alread
mentioned. It is partly due to the traditions of
when mediæval realism was the great enemy of
The Baconian protest against the "anticipation of n
was a relative truth when it was urged against a
writers who supposed that true theories could be a

necessity of attending to *axiomata media* was the ne
correction of the tendencies of mystics, who suppos
philosophy could attain its end by grasping at
absolute unity, and contented themselves, therefo
a unity which did nothing to explain the diff
But, when the former was turned into the d
assertion that the mind is, or ought to be, passive
process of knowledge, as having in itself no principl
explanation of things, and when the latter was turn
the dogmatic assertion that science can only proce
part to part and never from the whole to the part
relative truths became a source of error. And th
was confirmed and increased by the mistaken views
who first tried to correct it. For these, admittin
scientific truth is entirely derived from external exp
only ventured to assert the existence of *a priori* kn
alongside of, and in addition to, that which is *a po*
In other words, they sought in inner experience a b

eliefs which outward experience seemed unable to
. But this basis was soon found to be treacherous.
ection, observation of the inner life as opposed to
stinguished from the outer life, could be only an
tion of the facts of the individual consciousness as
and to base religion and morality on such a founda-
s to treat God and right as subjective phenomena,
do not necessarily correspond to any objective
Nor was this conclusion really evaded by the
n of the self-evidencing necessity of such ideas and
or of the principles upon which they are founded.
is necessity, as a subjective phenomenon, might be
ted for otherwise than by the supposition of their
ve validity. Such scepticism, further, was favoured
progress of science, which, as it advanced from
s to biology and sociology, became more and more in-
ent with the idea of an absolute breach between inner
ter experience, and narrowed the sphere which had
therto reserved for the former. Man, it was urged, is
art in a greater whole, not exempted from the law
on and reaction which connects all parts of that
with each other. His individual life contains only
links in a chain of causation that goes back to a
ing and onward to an end of which he knows
g. And, as Spinoza says, *eis quæ unaquæque res in
lo perseverat a causis æternis infinite superatur.*
to treat ideas which are only states of the individual
ousness as the explanation of the world, instead of
g them as phenomena to be explained by its relation
world, seemed to be an absurdity. The particular
and tendencies of the mind were to be regarded,
ultimate facts in reference to which everything
be interpreted, but rather as facts which are
lves to be referred to more general causes and
It thus appeared that the attempt to divide truth
a posteriori and an *a priori* part, the latter of
should find its evidence in an inner experience
former in an outer experience, is an illusive pro
If the *a priori* is reduced to the level of the *a
ori*, it becomes impossible to base on the *a priori*
eliefs that go beyond the range of subjective
ence. If the self and the not self are taken simply
erent finite things, which we can observe in turn,
elations must be brought under the general laws of
nnexion of finite things with each other; and the
nena of mind must be treated, like the phenomena
ter, as facts to be accounted for according to these

this of itself indicates a way of escape both from
rospective theory and from the empiricism to which
posed. For it suggests the question What is the
of those very laws which guide the procedure of
in accounting for facts, psychological facts among
! When a scientific psychologist of the modern
attempts to show how by habituation of the
dual and the race the necessity of thought expressed
law of causation was produced in the minds of the
t generation of men, it is obvious that his whole
gation and argument presuppose the law whose
s he is accounting for. A glaring instance of such
r reasoning is found in the writings of the most
nent representative of the school in the present day.
encer begins by laying down as a first postulate of
that necessity of thought must be taken as a
m of truth. It is by the continual aid of this
te that he constructs his system of nature, and
his psychological theory of the development of
ousness in man. Yet the main object of this
logical theory seems to be to account for the very
ities with which the author starts. Obviously such a

philosophy contains elements of which the aut
imperfectly conscious; for it involves that mind
only the last product but the first presupposit
nature, or, in other words, that in mind nature
upon its first principle. But to admit this is at o
lift the conscious being as such above the position
he would hold as merely a finite part of a finite worl
is to assert that nature has an essential relation to
sciousness which is developed in man, and that
growth of this consciousness we have, not an evo
which is the result of the action of nature as a sys
external causes *upon him*, but an evolution in which
is really "coming to itself," *i.e.*, coming to self-con
ness, *in him*.

Now it was Kant who first—though with a
limitation of aim—brought this idea of the rel
of thought and being to the consciousness of the
world. In the *Critique of Pure Reason*, thought, i
is not set up as an absolute *prius*, in relation to wl
existence must be conceived, but it is set up as th
of experience, and so of all existences which are obj
our knowledge. Experience is for Kant essentially
to the conscious self; it exists through the ne
subsumption of the forms and matter of sense und
categories, as, on the other hand, the consciousness
is recognized as essentially dependent on this proces
this view, the *a priori* and *a posteriori* factors of exp
do not really exist apart as two separate porti
knowledge. If they are severed, each loses all its
ing. Perceptions in themselves are void; catego
themselves are empty. We do not look outwards f
kind of truth and inwards for another, nor do we
by an external process, bring facts given as con
under principles recognized as necessary; but the
is the condition under which alone the *a posterior*
for us. Even if it is allowed that the facts of in
outer experience contain a contingent element or
given under the conditions of time and space, yet
time nor space nor the facts of experience conditio
them exist for us except as elements of an exp
which is organized according to the categories.

This is the essential truth which Kant had to e
It is marred in his statement of it by the pe
influence of the abstract division between con
matter given from without and necessary pr
supplied from within, a division essentially incon
with the attempt to show that the contingent m
necessarily subsumed under these principles, and
exists for us only as it is so subsumed. But Kant
puts into our hands the means of correcting h
inadequacy, when he reduces the inaccessible thing i
which he at first speaks of as affecting our sensibil
so giving rise to the contingent matter of experien
noumenon (*νοούμενον*) which is projected by reaso
The *Dialectic* exhibits the idea of thought as no
constituting finite experience but also reaching bey
though as yet only in a negative way. The min
this view, so far unlimited that it knows its own lir
is conscious of the defects of its experience, of t
tingency of its sensible matter, and the emptine
finitude of its categories; and by reason of this co
ness it is always seeking in experience an ideal whi
impossible to realize there. Thought measures exp
by its own nature, and finds it wanting. It d
a kind of unity or identity in its objects which it is
to find in the actual objects of experience. It
demand of reason which lifts man above a mere
existence, and forces him by aid of the categ
determine the matter of sense as a world of objects;
this finite world of experience can never satisfy the

son, the consciousness of it is immediately com-
with the consciousness of its limited and phenomenal
er. The student of the *Critique of Pure Reason*
but recognize the strange balance between the real
e phenomenal in which it ends, allowing to man the
usness of each so far as to enable him to see the
of the other,—so that by aid of the pure identity of
he can criticize and condemn the "blindness" or
lved difference of experience, and by means of the
eness and complexity of experience he can condemn
mpty" identity of reason.

order, however, to understand the full bearing of
criticism of knowledge, and at the same time to find
cting-point of the opposite currents of thought which
tely prevail in it, it will be necessary to consider
ject a little more closely. The lesson of the *Critique*
e gathered up into two points. In the first place,
refutation of the ordinary view of experience as
ing immediately given for thought and not con
d by it. In the second place, it is a demonstration
merely phenomenal character of the objects of
ence, *i.e.*, the demonstration that the objects of
ence, even as determined by science, are not things
nselves. Both these results require to be kept
in view if we would understand the movement of
t excited by Kant. On the one hand Kant had to
hat what is ordinarily regarded as real, the world
erience, is transcendently ideal, *i.e.*, is determined as
a priori forms of thought. On the other hand he
teach that the world so determined is empirically
ot transcendentally real, *i.e.*, its reality is merely
nenal. With the former lesson he met the man of
, and compelled him to renounce his materialistic
ation of the world as a thing which exists in
ndence of the mind that knows it. The world we
s a world which exists only as it exists *for us*, for
nking subject; hence the thinking subject, the ego,
be taken as an object like other objects, an object
enomena of which are to be explained like other
nena by their place in the connexion of experience.
g, however, thus repelled scientific materialism by
oof that the reality of experience is ideal, Kant
to proceed to the complete identification of reality
leality, and meets the claims of the metaphysician
he assertion that the reality of experience is merely
nenal. Hence he rejects any idealism that would
the negation of things in themselves beyond
nena, or the identification of the objects of experience
hese things. The reality we know is a reality which
only for us as conscious subjects, but this, though
he only reality we can know, is not the absolute
.

s, however, to be observed that the nature of this
tion between phenomena and things in themselves
to change as we advance from the *Analytic*, where
istence of such things is presupposed, to the *Dialectic*,
the grounds of that presupposition are examined.
t the opposition seems to be between what is present
sciousness and what is absolutely beyond conscious-
The matter of experience is regarded as given exter-
in the affections of the sensible subject,-- affections
by an unknown thing in itself, of which, however,
an tell us nothing. On the other hand the form of
ence, the categories and principles of judgment which
hese affections into objects of knowledge, are not pure
ssions of the real nature, the pure identity, of the
t in itself, but only products of the identity of the
relation to the sensibility and its forms of time
pace. Hence, on both sides we must regard expe-
as merely phenomenal, alike in relation to the noumenal object and in relation to the noumenal sub
which lurk behind the veil and send forth into
rience on the one side affections which become ob
through their determination by the unity of thought
on the other side an identity of thought which bec
self-conscious in relation to the objects so determin
itself.

Kant, however, having thus answered the questi
the possibility of experience by reference to two thin
themselves which are out of experience, is obliged t
himself how the *consciousness* of these two thing
themselves, and the criticism of experience in relati
them, is possible. And here, obviously, the oppo
can no longer be conceived as an opposition betwee
which is and that which is not in consciousness. Fo
things in themselves must be present to consciousn
some fashion in order that they may be contrasted wi
phenomena. If, therefore, phenomena are now reg
as unreal, it must be because we have an *idea of real*
which the reality of experience does not fully corres
In the *Analytic* Kant had been speaking as if the rea
sisted in something which is not present to the cons
subject at all, though we, by analysis of his experi
can refer to it as the cause of that which is so pr
Now in the *Dialectic* he has to account for the fact
the conscious subject himself is able to transcend
experience, and to contrast the objects of it as phenom
with things in themselves.

Now it is obvious that such an opposition is possibl
so far as the thought, which constitutes experience,
the same time conscious of itself in opposition t
experience it constitutes. The reason why experie
condemned as phenomenal is, therefore, not becaus
that which exists for thought as opposed to that
does not exist for thought, but because it imper
corresponds to the determination of thought in itself
other words, it is condemned as unreal, not becaus
ideal, but because it is *imperfectly* ideal. And the ab
reality is represented, not as that which exists w
relation to thought, but as that which is identical wi
thought for which it is. In the *Dialectic*, the
the noumenon is substituted for the thing in itsel
the noumenon is, as Kant tells us, the object as it
for an intuitive or perceptive understanding, *i.e.*, an
standing which does not synthetically combine the
matter of sense into objects by means of categorie
whose thought is one with the existence of the obj
knows. It is the idea of such a pure identity of kn
and being, as suggested by thought itself, which le
to regard our actual empirical knowledge as imperfe
its objects as not, in an absolute sense, *real* objects.
noumena are not, therefore, the unknown causes by
action and reaction conscious experience is produced
represent a unity of thought with itself to which i
experience inadequate. This higher unity of though
itself is what Kant calls reason, and he identifies i
the faculty of syllogizing. Further, he finds in the
forms of syllogism a guiding thread which brings
the recognition of three forms in which the pure u
reason presents itself to us in opposition to the
synthetic unity of experience, a psychological, a
logical, and a theological form. In each of these
the empirical process of knowledge is accompanied, g
and stimulated by an idea which nevertheless it is
to realize or verify. In psychology we have ever p
to us an idea of the identity of the self, which is
realized in our actual self-consciousness, because th
of which we are conscious is manifold in its state
because it stands in relation to an external world,
idea of simple identity is, therefore something we n

is as the goal of an ideal psychology, to which we proximate in so far as we can trace unity of faculty all the differences of mental phenomena, but to ve can never attain owing to the nature of the matter hich we deal. Again, in our scientific attempts to our external experience, the unity of reason takes n of an idea of the world as a completed infinite which contains all the object known to us and all possible objects; but this cannot be realized in perience which is conditioned by space and time, therefore, ever incomplete. The idea of totality efore, an *ideal*, which guides and stimulates our e progress, without which such a thing as science ot exist, but which at the same time can never be i by science. Lastly, the unity of reason takes a rm in which identity and totality are combined, dea of a unity in which all differences, even the ce of subject and object, are transcended, the idea ty of all things with each other and with the mind ws them. This idea also is one which science can surrender nor realize. It cannot surrender it f giving up that striving after unity without which would not exist, and it cannot realize it, for the e between the world, as it is presented to us in experience, and the subjective determination of nking consciousness cannot be overcome. We can, use the idea that the world is an organic whole, ined in relation to an end which consciousness sets lf, as an *heuristic* principle to guide us in following nnexion of things with each other; but, as we cannot n of any such idea anticipate what the facts of l experience will be, so we cannot prove that for a other than ours the unity of things which we repre- this way might not take a quite different aspect, we have reason to think it would; for, while we think of a designing mind as using material which existence and nature independent of the purposes h they are put, the absolute mind must be conceived ature the materials themselves by the same act y they are determined to an end. We must con- , in short, as an intuitive understanding for which d means, objective and subjective, are one, or, in words, as an intelligence whose consciousness of s or contains the existence of all that is object

new view of the things in themselves as *noumena* als of reason involves a new attitude of thought s them different from that dogmatic attitude which sciously adopted in the *Analytic*. Accordingly, we d Kant speaking of them, not as things which exist dently of their being conceived, but as "problal conceptions" of which we cannot even determine r they correspond to any objects at all. They are ative notions which have a negative value, in so far keep open a vacant space beyond experience, but enable us to fill that space with any positive realities. are like dark lanterns which cast light upon the cal world, and show what are its boundaries, but heir own nature in obscurity. All that we can say noumenal self or subject is that it corresponds to the implied in all knowledge, but whether there is such independent of the process of empirical synthesis e self consciousness which accompanies that process, not tell. All that we can say of the noumenal reality objective world is that it corresponds to the idea objects of experience as a completed whole in them apart from the process whereby we know them, but r there is any such real world independent of the s of experience it is impossible to say. Lastly, all e can say of God is that He corresponds to the idea of the unity of all things with the mind that knows th an ideal which is involved in all knowledge,- but w the realization of this idea in an intuitive underst is even possible we have no means of determining ever we may suspect that understanding and sensibi "branches springing from the same unknown root." *Criticism of Pure Reason* ends, therefore, in a k seesaw between two forms of consciousness - a th consciousness, which transcends experience and sets us an idea of absolute reality, but which cannot to any knowledge or even certitude of any corresponding to this idea, and an empirical con ness, which gives us true knowledge of its objec whose objects are determined as merely phenomen not absolutely real.

The equipoise thus maintained between the em and the intelligible world is, however, in the *Cri Practical Reason*, overbalanced in favour of the What the theoretical reason could not do "in that weak through the flesh," through its dependence very empirical consciousness which it sought to tra is possible to the practical reason, because it is pr determined by itself. In our moral consciousness ourselves under a law which calls upon us to *act* as who are absolutely self-determined or free, and therefore, as it tells us that our intelligible self is our re and conclusive, determines our empirical self in c with it as phenomenal. Thus the moral law gives to the intelligible world; or, as Kant expresses i idea of an intelligible world is a point of view beyo phenomenal which the reason sees itself compelled up, in order to think of itself as practical." I words, the moral law presupposes freedom or determ in the rational being as such, and makes him rega self, not merely as a link in the chain of cond existence, in time and space, but as the original of his own life. The blank space beyond the phen thus begins to be filled up by the idea of a free ca which again postulates a world adequate and co able to itself. And the man who, as an empiric in ality, is obliged to regard himself merely as an ind being determined by other individual beings and is authorized as a moral being to treat this a necessity as having its reality in freedom, and to loc himself as the denizen of a spiritual world where is determined for him from without which is not the expression of his own self determination from "Thus we have found, what Aristotle could not fixed point on which reason can set its lever, not present or future world, but in its own inner freedom,- a point fixed for it by the immovable law, as a secure basis from which it can move the will, even against the opposition of all the po nature. [1] Starting from this idea of freedom, th Kant proceeds to reconstruct for *faith* the unseen which in the *Critique of Pure Reason* he had denie object of *knowledge*. Nor is he content to lea two worlds in sharp antithesis to each other, but the *Critique of Practical Reason*, and still more *Critique of Judgment*, he brings them into relation other, and so gives to theoretical reason a l authority to use for the explanation of the phen world those ideas which of itself it might be inc regard as illusive.

In all this, however, it is difficult to avoid s partial retractation of Kant's first view as to the irreco opposition of the phenomenal and the noumenal. the first place, the moral imperative is addressed t

[1] Kant, i. 638 (Rosenkranz's edition).

is at one and the same time regarded in both
ters, and which is called upon to subsume under the
law acts which otherwise derive their character and
g from the relations of the phenomenal world. That
rticular nature of men as phenomenal individuals
the means of realizing the universal law of reason is
l in all Kant's statements of the latter, and particu
his conception of men as constituting together a
dom of ends"; for it is difficult to conceive this
m otherwise than as an organic unity of society, in
each individual, by reason of his special tendencies
pacities, has a definite office to fulfil in realizing
iversal principle that binds all the members of the
m to each other. The *summum bonum*, again, is
consist in the union of happiness with goodness,
the empirical conditions of man's individual life as
ble subject with the pure self-determination of the
ible self; and God is postulated as a *Deus ex*
a to bind together these two unrelated elements,
ption which shows the difficulty into which Kant
ought himself by defining them as unrelated. Still
bvious is the effort of Kant to get beyond the
n of his first view of things in the *Critique of*
ent. For in that work he maintains that the con-
ess of the beautiful and the sublime is or involves
ony of the understanding or the reason with sense;
hat is still more important, he points out that the
organic unity, without which we cannot explain the
nena of life, contains in it a possibility of the recon
n of freedom and necessity, of the intelligible and the
nenal. This idea, he argues, we are authorized by
ral consciousness to apply to the whole course of the
in the phenomenal world, and so to regard it as a
to realize the moral ideal. No doubt he again
y retracts this view when he declares that we must
he idea of final causality as merely a *subjective*
le of judgment, which, even in the case of living
is to be regarded only as necessary for us as finite
ences. But such saving clauses, in which Kant
to the dualism with which he started, cannot hide
s how near he has come to the renunciation of it.

n we regard Kant in this way as asserting from one
f view an absolute limit which from another point
v he permits us to transcend, it becomes obvious
s philosophy is in an unstable equilibrium, which
but be disturbed by any one who attempts to
or even to restate his ideas. Hence we need not
that those who take in earnest his denunciations
attempt to transcend experience generally, like
or Huxley,- reject as worthless all Kant's later work;
at, on the other side, those who take in earnest his
t freedom, of organic unity, of an intuitive under
g, and of a *summum bonum* in which freedom and
ty meet together, are compelled to break through
bitrary line which he drew between knowledge
lief. In favour of the former course it is easy in
places to appeal to the letter of Kant. In favour of
ter it need only be pointed out that, in Kant's view,
erience rests upon, or is in its development guided
se ideas which yet he will not permit us to treat as
of knowledge. Hence the principles of the *Critique*
legitimately be used against metaphysic, except
se who are prepared to admit the ideas of reason, up
point to which he admits them, as ideas that limit
rect our experience,—while rejecting all use of them
light upon that which is beyond experience. "In
words, they must maintain the possibility of a purely
ve knowledge, of the knowledge of a limit by one
et cannot go beyond it. They must show how we
ve an ideal of knowledge which enables us to criticize
experience without enabling us to transform it, they
show how ideas of the supersensible can so far be
to our thought as to make visible the boundaries
prison of sense in which we are confined, without
way enabling us to escape from it.

Is this possible? We may gather up the K
antithesis in the assertion that experience is the im
realization of an ideal of knowledge, derived from
with materials, derived from sense and understandi
nature of which is such that they can never be b
into correspondence with the ideal. But this ideal, i
three forms, as we have seen, is simply the idea of
unity or identity in which all differences are
dissolved whether they be the differences of the
of the outer life, or finally the difference of inn
outer, subjective and objective, from each other.
view therefore is, in effect, this, that thought
with it the consciousness of an identity or unity, to
our actual experience in none of its forms fully corres
On the other hand, Kant does not hesitate equally
demn the identity of thought as "empty" and subj
because it does not contain in itself nor can evol
itself the complex matter of experience. Bu
alternate condemnation of experience as unreal fr
point of view of the ideas, and of the ideas as unrea
the point of view of experience, seems to show that
unreal, as being abstract elements, which have no val
in their relation to each other, and which lose all thei
ng when separated from the unity to which they
According to this view, ideas and experience, n
and phenomena, if they are opposed, are also nec
related to each other. If our empirical consciousn
the world of objects in space and time, as determ
the categories, does not correspond to the unity or i
of thought which is our ideal of knowledge, yet th
of unity or identity is set up by thought in *relat*
experience, and cannot, therefore, be essentially i
cilable with it. The two terms may be opposed, bu
opposition cannot be absolute, seeing that they
essential relation to each other. It is a great logica
not to discern that a negative relation is still a re
i.e., that it has a positive unity beyond it. This
unity may not, indeed, be consciously present to
our immediate apprehension of the relation in qu
but it is necessarily implied in it. Now it is just h
in his separation of noumena and phenomena, Kant
to note their essential relativity that he is forced to
the former as a set of abstract identities, of which n
can be known, and the latter as the imperfect prod
a synthesis which can never be completed or brough
true unity. Yet the value of his whole treatment
ideas of reason in relation to our intellectual and
experience arises from the fact that in practice h
not hold to this abstract separation of the two el
Ideas absolutely incommensurable with experienc
neither stimulate nor guide our empirical synthesis
could not even be brought into any connexion w
When, therefore, Kant brings them into this connex
necessarily alters their meaning. Hence the pure a
identity which excludes all difference is changed,
application, into the idea of an organic unity, of wh
highest type is found in self-consciousness, with its
parent difference of the subjective and objective se
would be absurd and meaningless to say that science s
reduce experience to an abstract identity, in which t
no difference, unless for this were tacitly substitute
is really an entirely different proposition, that scienc
to find in the infinitely diversified world of space an
that unity in difference of which self-consciousness
itself the pattern. It is in reference to the forme

utity—the abstract oneness of formal logic—that proves that it is impossible for experience to be dequate to ideas. But it is only of the latter kind tity—the oneness of self-consciousness—that it can that it furnishes a guiding principle to scientific gation or an ideal of knowledge. The same con is still more evident in Kant's account of our moral nce, in dealing with which he directly attempts to nthetic propositions out of the pure identity of in other words, to draw definite moral laws out logical principle of non-contradiction. Whatever he attains is gained by substituting for the formal le of *self-consistency* the positive idea of *consistency e self*, and again by conceiving this self as a concrete ual, the member of a society, and so standing in al relation to other selves. The pure abstraction ll the external results of action and from all motives re, which at the beginning of the *Metaphysic of* Kant declares to be essential to morality, is modified leed transformed, as we go on, by the admissions her rational beings are *not* external to us in any hat excludes their good from being an end of our our, and that the desires are *not* irrational and al except in so far as they are directed to the es of the sensuous individual (which in a conscious they never entirely are). Both in the speculative the practical sphere, therefore, the absolute opposi- the ideal or noumenal to the empirical disappears, as Kant attempts to apply it. For in both the t identity of formal logic, which is really the g of the noumenon as absolutely opposed to and nensurable with experience, gives way to the unity onsciousness, a unity which is so far from being *ly* opposed to the difference of the empirical usness that it necessarily implies it. For self- usness presupposes the consciousness of objects; it is opposed to that consciousness, it is essentially ed with it, and therefore its opposition cannot be d as absolute, or incapable of being transcended.

e considerations may throw some light on the of the *Analytic* and *Dialectic* of Kant, and on the of the opposition of noumenon and phenomenon presented in the latter. In the deduction of the ies, Kant pointed out the essential relation of the e world of experience to what he called the endental unity of apperception"; *i.e.*, he pointed t the unity of consciousness is implied in all its This unity, he further showed, must be conceived able of self-consciousness"; but it actually becomes us of self only in relation, though also in opposi- the other objects determined by it. Now it is this usness of itself in opposition to other objects which ource of Kant's "ideas of reason," of the dissatisfac- the mind with its empirical knowledge, even in its ic form, and of the demand for a higher kind of know- which experience is not adequate. That a standard p for experience by which it is condemned is simply of the further development of that unity which is in experience—a result of the progress of thought nsciousness to self-consciousness, and of the contrast n the former and the latter. The problem with Kant's *Dialectic* attempts to deal, and which it treats uble, is, therefore, simply the problem of *raising con- ss to the form of self-consciousness*; in other words, of ng to a knowledge of the world of experience as not a "synthetic," and therefore imperfect, unity of things l to each other, but as an organic unity of transparent nces, a self-differentiating, self-integrating unity, such ns to be presented to us in pure self-consciousness. an this problem be regarded as insoluble; for the unity of self-consciousness is identical with the u consciousness; it is only that unity become self-co Hence the point of view at which consciousness a consciousness seem to be absolutely opposed to each o the highest point of view which Kant *distinctly* rea can be regarded only as a stage of transition from th at which their relative difference and opposition is developed to the point at which they are seen to factors or elements of a still higher unity.

The later philosophy of Germany, from Kant to is little more than the development of the idea just in its twofold aspect. In the first place, it is an a to show what is involved in the idea of thought consciousness as in itself an organic whole, a many a unity which expresses itself in difference, yet so t difference remains transparent, and therefore is imme recognized as expression of the unity. In the place, it is an attempt to bridge over the difference b thought or self-consciousness and the external w experience, and to show that this opposition subordinated to a higher unity. Or, to put it more d the idealistic philosophy of Germany seeks, on t hand, to develop a logic or metaphysic which base not, like formal logic, on the idea of bare identity, the idea of self-consciousness; and, on the other h show, in a philosophy of nature and spirit, how, by of this logic, the opposition of thought to its ob of the *a priori* to the *a posteriori* in knowledge, transcended. In the third and fourth sections article something more will be said of the man which this task was fulfilled. Here only a few wo necessary to sum up the results reached, and to giv distinctness to the new ideal of knowledge which results suggest. We have seen that Kant's critical a involved two things, on the one hand, the asserti the existence we know is necessarily existence for th and, on the other hand, the denial that that which for our thought is absolute reality, a denial which involves the presence to our thought of an ideal of ledge, by which our actual knowledge is cond This ideal, however, was falsely conceived by Kan identity without any difference, and, in this sense, h not hesitate to apply it even to self-consciousness For, in a remarkable passage,[1] he attempts to prov the consciousness of self is not a knowledge of the s a simple reference to the duality of the self knowi the self known, arguing that the ego "stands in i way," just because it exists only *for itself*, *i.e.*, bec knowing itself it presupposes itself. Kant evidently that to know the real self it would be necessary to app it in simple identity as purely an object without re to a subject, or purely a subject without reference object. Yet to this it seems sufficient to answer tha an object or subject would lose its character as ob subject and become equivalent to mere being in g and that, as such being is a mere abstraction, to k cannot be the ideal of knowledge. If therefore the unity or identity of thought which is not realized perience, and in reference to which we can regard exp as an imperfect form of knowledge, it cannot be fo this abstract identity of being. In truth, as we have is found in that very idea of self-consciousness whic is criticizing. Just because we are self-conscious, and fore oppose the unity of the conscious self to the ma ness of the world in space and time, do we seek world of space and time for a transparent unity wh cannot at first find there. But, when this is seen, in Kant himself the partial solution of the dif

[1] *Kritik*, p. 279 (Rosenkranz's edition). *cf.* Hegel, v. p.

nsciousness presupposes consciousness; for, while the ension of objects in consciousness is possible only ation to the unity of the self, yet it is only in n to and distinction from these objects that we are us of that unity. Hence the two opposites, self t-self, are bound together, and presuppose a unity reveals itself in their opposition, and which, when explicit, must reconcile them. If, therefore, self usness, in its first opposition to consciousness, gives an ideal of knowledge to which our empirical dge of objects is inadequate, this arises from the at not only empirical knowledge but also the ideal ch it is opposed is imperfect, or that they both to a unity which is manifested in their difference, hich is capable of containing and resolving it. In words, the opposition of science to its ideal, which has stated in his *Antinomies*, is not an absolute ion, but one the origin and end of which can be

opposition reaches its highest point in the con- etween the transparent unity of self consciousness, ch the difference of knower and known is evanescent, e essential manifoldness and self-externality of the n space, in which the differences seem to be insoluble. ust, indeed, think of self-consciousness as having life f and therefore as differentiating itself from itself; s differentiation is held within the limit of its unity, separation of movements which are separated only as re united. On the other hand, the world in space s itself as the sphere of external determination, in things are primarily disunited and act only as they ed on from without, and in which this external ce never goes so far as to destroy their reciprocal lity. In this sense it is that the opposition of mind tter was taken by Descartes, and it is a survival of he mode of thought that leads many even now to bsolute lines of division between *a priori* and *a ri*, between ideas and facts, between spiritual and . Kant and Fichte give a new aspect to the y by showing that the difficulty is one of recon- consciousness and self-consciousness, and that in usness there is already present the unity which is ted in self-consciousness, as, on the other hand, it through consciousness and in opposition to it that sciousness is possible. And Fichte made a further hen he attempted to show that the categories and the f perception, time and space, which Kant had taken plicable facts, are implied in this contrast of con ess and self-consciousness. The error that clings to s speculations is, however, that he treats conscious- erely as a necessary illusion which exists simply view to self-consciousness, and hence is led to regard sciousness itself—because it is essentially related necessary illusion—as a schema or image of an vable absolute. In fact, in the end Fichte falls pon the abstract identity in which Kant had found menon, and so ends his philosophy with mysticism. Schelling, though he saw that the absolute unity e one that transcends the difference of self and not- id not finally escape the tendency to merge all ce in absolute oneness. On the other hand, it was leavour of Hegel to proceed in the opposite way,— lose self-consciousness or subjectivity in a mere of substance, but rather to show that the absolute nce can be truly defined only as a self-conscious . And just because he did this he was prepared a further step, and to regard the external world, Fichte regarded it, as merely the opposite of spirit, Schelling regarded it, as merely the repetition and al of spirit, but rather as its necessary manifestation or as that in and through which alone it can realize His doctrine therefore might be summed up in two p tions,—first, that the absolute substance is spiritual conscious, and, secondly, that the absolute subject o can be conceived as realizing itself only through th world of externality which at first appears as its op In both respects Hegel's philosophy reverses the *ci tion* of mysticism, and teaches that it is only throu exhaustion of difference that the unity of science, of the mind contains in itself the certitude, is to be re For mind or spirit, viewed in itself, is conceived as differentiating unity, a unity which exists only t opposition of itself to itself. And it is but a ne result of such a conception that spirit can fully rea unity only through a world which in the first i must present itself as the extreme opposite of Hence the process of thought in itself, which is ex in the logic, ends in the opposition to thought of a which is its negative counterpart. And the "a spirit" of Hegel is thus, not pure self-consciousne that more concrete unity of self-consciousness wit which it attains through and by means of this worl

The effect of this view upon the relation of metaph science, which we are at present considering, is noti It does not, as is often supposed, supersede science *a priori* construction of the universe, nor does it le results of science unchanged and simply provide deeper foundation. The latter was the point at Kant and Fichte stopped; for, while they showe relativity of experience to the principle of self-consci they conceived that the function of metaphysic is com in showing the phenomenal character of the obj science, and in reserving a free space beyond th nomenal world for "God, freedom, and immort Schelling, on the other hand, as he did not adop merely negative view of the relation of spirit to nat of *a priori* to empirical truth, was obliged to rein the latter by the former. As, however, he did not nize any distinctions which were not merely quanti he was led to apply the same easy key to every loc to think that he had explained all the different fo existence, organic and inorganic, when he had pointed out a certain analogy between them. The physic of Hegel, whatever may be said of the philosophy of nature produced by its author, conta necessity for any such arbitrary procedure. In his indeed, he attempts to give us *in abstracto* the mov of thought in itself, from its simplest determinat being as qualitative or quantitative, through the re categories of substance and cause, up to its full con ness of itself in its organic unity.[1] And in so doing course gives us an account of the various categories science uses in the interpretation of nature. He attempts to show that the highest categories of scie in themselves imperfect and self-contradictory,—in words, that they mark a stage of thought whic short of that unity of being and knowing after science is striving, and which is the presupposit well as the goal of all intelligence. But, while h this, he clearly acknowledges two things,—on t hand that nature is essentially different from pur consciousness, and that therefore logic can ne direct evolution of its categories anticipate the inv tions of science, and, in the second place, that th interpretation of nature through the highest cat presupposes its interpretation by the lower categori cannot be directly achieved without it. In other

[1] This subject—the progress of thought from lower to high gories and methods—will be more fully discussed in the third

must first determine the laws of nature according
principles of causality and reciprocity, etc philosophy
in a position to discover the ultimate meaning of
by the aid of higher principles. "The philosophy
ture," says Hegel, "takes up the material which
al science by direct dealing with experience has
ed for it at the point to which science has brought
l again transforms this formed material without
back to experience to verify it. Science must,
ore, work into the hands of philosophy, in order that
ophy in its turn may translate the lower universality
understanding realized by science into the higher
sality of reason, and may show how in the light of
igher universality the intelligible world takes the
of a whole which has its necessity in itself. The
ophic way of looking at things is not a capricious
t, once in a way for a change, to walk upon one's
after one has got tired of walking upon one's feet, or
nstorm one's work a day face by painting it over;
st because the scientific manner of knowing does not
the whole demand of intelligence, philosophy must
ment it by another manner of knowing."[1]

result then may be briefly expressed thus. Kant
s succeeded in showing the relativity of the object of
edge to the knowing mind. He thus pointed out
the ordinary consciousness, and even science, are
t and imperfect modes of knowing, in so far as in
determination of objects they take no account of a
which is always present, to wit, the knowing subject.
their purposes, indeed, this abstraction is justifiable
ecessary, for by it they are enabled within their pro
l limits to give a more complete view of these objects
ir relation to each other than if the attempt had
made to regard them also in relation to the knowing
t. At the same time the scientific result so arrived
mperfect and incomplete, and it has to be recon
l in the light of a philosophy which retracts this
ional abstraction. For it must be remembered that
t that science looks at things only in their relation
h other, and not to the knowing mind, narrows the
s of view or categories under which it is able to
l them, or, in other words, limits the questions which
nd is able to put to nature. Just because science
not treat its objects as essentially related to the mind,
nable to rise to what Hegel calls the point of view
son, or of the "notion"; *i.e.*, it is obliged to treat
s and their relations merely under a set of categories,
ghest of which are those of causality and reciprocity,
is incapable of attaining to the conception of their
e unity. In other words, it is able to reach only a
etic unity of given differences, and it cannot discover a
pl of unity out of which the differences spring and
ch they return. Now philosophy goes beyond science
ecause, along with the idea of the relativity of things
mind, it brings in the conception of such a unity.
ighest aim is, therefore, not merely, as Kant still
to secure a place for the supersensible beyond the
of experience, but to reinterpret experience, in the
of a unity which is presupposed in it, but which
t be made conscious or explicit until the relation of
ience to the thinking self is seen, the unity of all
s with each other and with the mind that knows them.

Relation of Metaphysic to Psychology. It has already
shown that the doctrine that the thinking subject is
pposed in all objects of knowledge or, in other
, that existence means existence for a conscious self
not to be taken in a psychological sense. The idea
ll science is based on psychology, and that, therefore,

[1] Hegel, vii. p. 18.

metaphysic and psychology are identical, cannot be re
by any one who has entered into the full meaning
Kantian criticism. It is, however, so natural a mi
pretation of it, and it is so much favoured by the le
the very book in which it was first decisively re
that it will be useful to point out more directly the f
involved in it, especially as this will place us in a
position to determine the true relation of the two pa
philosophy thus confounded.

The misunderstanding first took a definite form
introduction to Locke's *Essay*, in which he propo
provide against any undue application of the intel
powers of man to problems which are too high for
by first examining and measuring the powers them
Stated in this way, it is obvious that the pr
involves an absurdity; for we have nothing to m
with, except the very powers that are to be measured
see round our knowledge and find its boundary, we
stand outside of it, and where is such a standing gro
be found? We cannot by knowing prescribe lim
knowledge, or, if we seem to be able to do so, it ca
be because we compare our actual knowledge with
idea of knowledge which we presuppose. In this w
ancient sceptics and modern writers like Sir W. Ha
and Mr Spencer who have followed them turne
duality involved in the idea of knowledge against its
and argued that, because we cannot know the
except as different from and related to the subje
cannot know it as it is in itself. Obviously i
argument it is involved that in true or absolute kno
the object must not be distinguished at all from the s

to which the easy answer is that *without* such
tion knowledge would be impossible. The sceptic
ment, therefore, lands us in the unhappy case pi
in the German proverb: "If water chokes us, wha
we drink?" The object cannot be known if
distinguished from the subject, and it cannot be kn
it is *not* distinguished from the subject. Obvious
one objection is as good as the other, and both co
only show that the idea of knowledge involves dist
as well as unity, and unity as well as distinction.
sceptic insists on one of these characteristics to the ex
of the other, and condemns our actual knowledge b
it contains both. In Kant there is undoubtedly som
of the same fallacy, in so far as the idea by contras
which he condemns the objects of experience as
menal is the idea of an abstract identity witho
difference; but we have seen that with him this a
identity is on the point of passing into an alto
different idea the idea of self-consciousness as the
knowledge.

It appears, then, that the idea of measuring our
before we employ them rests on a paralogism; for w
really meant is that we abstract one of the elements
idea of knowledge, and then condemn knowledge for
other elements in it. It is possible to criticize an
demn special conceptions as not conforming to ou
of knowledge; but it is not possible to criticize th
of knowledge itself; all we can do is to explain it.
possible to see the limited and hypothetical chara
certain of our ideas or explanations of things, beca
are conscious that in developing them we have left
account certain elements necessary to the whole
but this criticism itself implies, as the standard to wh
appeal, a consciousness of truth and reality, a consci
which we cannot further criticize. Here, therefo
come upon what must seem to all who think it adm
to question the very possibility of knowledge an ine
reasoning in a circle. We can answer objections o
means of the very idea which they dispute. I

is nevertheless a good one; for the objector also within the very circle which he seeks to break, and means of breaking it except itself. As soon as he he can be refuted by his own words; for his doubts resuppose that unity of the intelligence and the ible world which he pretends to deny.

error, however, cannot be fully corrected until we r what gives it plausibility. The confusion of the ysical with the psychological problem is due to the at the being who is the subject of knowledge, for all exists that does exist, appears to be one, and only the many objects of knowledge. When we say istence means only an existence for a thinking self, n to be identifying the whole world with the feelings eas of men, *i.e.*, with certain phenomena that belong life of a class of beings which only forms a part of orld,—phenomena, moreover, that are not exactly ne in any two of that class of beings. If we are to this difficulty it is obvious that we must be able to e the conscious self or subject, as it is implied in owledge, from the nature of man as a being who gh formally self conscious" is yet "part of this par-

rld," *i.e.*, one of the objects which we know along with distinction from other objects, and in whom "the sciousness which is in itself complete, and which ompleteness includes the world as its object," is only ssively realized.[1] Metaphysic has to deal with con- of the knowable, and hence with self consciousness unity which is implied in all that is and is known. logy has to inquire how this self-consciousness is l or developed in man, in whom the consciousness grows with the consciousness of a world in space ne, of which he individually is only a part, and to parts ch only he stands in immediate relation. In con- g the former question we are considering the sphere which all knowledge and all objects of knowledge are ed. In considering the latter we are selecting one lar object or class of objects within this sphere,— gh no doubt it must make a great difference in our ent of this object that we have to consider it as g not only for us but for itself. If nature "becomes scious in man," it is impossible to treat man as one among the other objects of nature. But it less true that he *is* one of those objects, and, in this of view, the department of science and philosophy eals with his life is as distinct from metaphysic- deals with the conditions of all knowing and bein, s astronomy or physics. In both cases we have us objects which we may consider in themselves from their relations to the conscious subject, and n cases we must take cognizance of these relations if uld have a complete and final view of those objects. ossible to have a purely objective anthropology or logy—which abstracts from the relation of man to nd that knows him—just as it is possible to have a objective science of nature. Such a natural science , however, will necessarily abstract at the same time he fact that in man is manifested that universal le in relation to which all things are and are known. er words, it will omit that distinctive characteristic of being in virtue of which he is a subject of knowledge moral agent. Hence the abstraction in this case is likely to lead to positive error, more likely to produce ly an imperfect but a distorted view of the object. anic nature, if we take it *in itself*, is not untruly d, under the categories of causality and reciprocity, collection of objects externally determined by each ; the error lies only in taking it as if it could exist

[1] Hume, vol. i. p. 131 (Green's edition).

in itself. Even organic beings do not suffer much injus in being brought under such categories; for, though living and still more as sensitive beings, they involv themselves and in their relation to the world a kin unity of differences to which the categories of exte relation imperfectly correspond, yet they are not unities *for themselves*, but only *for us*. In other words, principle through which they are and are known is external to them. Hence also they are determined outward influences, though these influences act rathe stimuli to what we may call the self-determined move of their own life than as mechanical or chemical fo which change it. But in man, in so far as he is self- scious, and it is self consciousness that makes him - the unity through which all things are and are kn is manifested; and therefore he is emancipated, o least is continually emancipating himself, from the of external influence. Nature and necessity exist him as that from which his life starts, in relation to w he becomes conscious of himself, against which he to assert himself, and in the complete overcoming which lies the end of all his endeavour. Nature is negative rather than the positive starting point of existence, the presupposition against which he reacts ra than that on which he proceeds; and, therefore, to treat simply as a natural being is even more inaccurate misleading than to forget or deny his relation to na altogether. A true psychology must, however, avoid errors: it must conceive man as at once spiritual and natu it must find a reconciliation of freedom and necessity. must face all the difficulties involved in the concep of the absolute principle of self consciousness, thro which all things are and are known,—as manifesting i in the life of a being like man, who "comes to himse only by a long process of development out of the un sciousness of a merely animal existence.

This problem first presented itself in a distinct for the discussions of the Socratic school as to the natu knowledge, discussions which turn mainly upon the rela of the conscious to the unconscious element in thou Socrates, by his method more than by any direct s ment, drew attention to the fact that all particular j ments in morals involve or presuppose a universal princ At the same time he pointed out that, so far from universal principle being known to those who are ntinually making such judgments, they are not conscious of its existence. They constantly use ge terms whose meaning they have never even thought defining. Th beginning of a rational life for them therefore lie in t heir becoming conscious of their ignor *i.e.*, conscious that they have been all along judging, therefore acting on untested and even unknown ass tions. They must bring the unconscious universal t light of day and define it, for until that is don impossible to live a moral, that is, a rational life. 'V is knowledge," *i.e.*, it is acting, not according to opin or particular judgments, whose universal is unknown which therefore may be regarded as expressing merel impulses or habits of the individual,—but in view universal principle determined by reason.

The onesidedness of this view—which absolutely demns as vice all virtue that is not based on cons principle—was partly corrected by another part o doctrine of Socrates, who taught that knowledge is thing that must be evolved from within the mind, an merely communicated to it from without. For this in that the moral principle may be present in men's m and may rule their thoughts and actions, long b they become directly conscious of it. They are rat although they have never thought about reason, and

wait for scientific ethics to judge and act morally, re than they wait for logic to reason correctly. It ine of thought which is universalized and mythically ed by Plato in his doctrine of "reminiscence." ing to this myth, we were conscious of ideas or als in our pre-natal state, we forgot them in the of birth into this mortal life, but in feeling or the rapture of the poet or the lover we recall them ntified or confused with individual objects which ke them, or partake in them." The same explana given of the practical skill of the general and the an, and even of the "right opinion" which guides inary good man. Such opinion is neither knowledge norance, not knowledge, for general principles or e not in it present to the mind *as* ideas, and there e particular cannot be distinctly subsumed under yet not ignorance, for the ideas are after all present, wrapped up in the particulars or confused with . Nay, in the *Theætetus*, Plato endeavours to show pure particular without the universal, sensations ideas, cannot enter into our consciousness at all, t therefore the lowest point to which a conscious an descend is "opinion," in which particular and l, sensible and intelligible, are mingled together. words, no conscious being can apprehend the ar except through the universal, though that uni- may be present only *in* consciousness and not *to* e task of philosophy is therefore only to make men et themselves," *i.e.*, to make *self-conscious* that ulty of thought in which all rational beings se," or which, in the language of later philosophy, utes reason. The imperfection of Plato's view lay, , in this, that, while he clearly recognized that the n of all consciousness of the particular is the l, he did not see with equal clearness that the l has a meaning only in relation to the particular. s tendency to separate universal from particular is ly accompanied by a tendency to set the subjective the objective, and to regard the world, not as the tation of reason, but as a dualistic world, in which is chained to a lower principle a world which e t only give a hint or suggestion to the mind to t to recollect itself and recover for itself its own . Thus the false method of introspection, the *ward* road' of mysticism, was at least opened up o, if he did not altogether forsake the narrower der way to the spiritual world through nature and nce.

great step in advance taken by Aristotle was due to ng the danger of this tendency. Those, however, ve maintained that Aristotle is the great *a posteriori* pher, as Plato is the great *a priori* philosopher, tirely mistaken the bearing of Aristotle's criticism Platonic theory. As strongly as Plato does Aristotle n that reason is ὅσαρχα τὰ νοητά, and that, re, the apprehension of truth *by* the mind is not a eternal communication *of* it *to* the mind, but rather mind coming to a consciousness of itself. As firmly does he declare that truth in its highest form is dencing, *i.e.*, that the principles of science, the laws re, when once they have been discovered, are seen true by their own light. His statements to this have been neglected or explained away, because ere supposed to be inconsistent with his still more tly reiterated assertions that it is only from nce and by induction that the truth of things can covered. Writers of a later day, who came to le with an idea of a fixed opposition between *a* and *a posteriori*, and who held that the only possible tives were *either* to divide knowledge between the two *or* to explain away one of them,—could not comp that Aristotle might be in earnest *both* in asserti knowledge is derived from experience *and* in asserti it is an apprehension by reason of that which is id with itself and needs no extraneous evidence Aristotle started with no such fixed opposition. contrary, any one who reads the last chapter *Posterior Analytics* will see that he had no diffic maintaining that knowledge begins in the apprehen τὸ καθ' ἕκαστον in sense perception, and that it p from many perceptions to experience, and from experiences to science; while at the same time he d that the principles of science have their evidence i selves. And the meaning of this declaration is sh the *De Anima*, where we find him speaking of knowl the realization in the "passive reason" of man of an reason" which is eternal and unchangeable, and w the consciousness of itself includes the knowledg things. Of this realization, indeed, there is in ma the potentiality or capacity, but just because this is or universal capacity, because, as Aristotle puts it, it quality or determination of its own to stand between its objects, it is a capacity in which the absolute rea realize itself, a capacity of knowing all things. H have Plato's myth of reminiscence freed from the m of memory, and reduced to scientific terms; for tha simply meant that the evolution of knowledge development of the mind to the consciousness of its of all that is potentially in it. Only, by the combi of this doctrine with the idea of the necessity of ind Aristotle at the same time guards against the subjective interpretation to which in Plato it was For the process by which the mind "comes to its conceived as a process by which at the same time from the particular to the universal, from the ἡμῖν to the γνώριμα ἁπλῶς, from the bare apprehen the facts of experience to the knowledge of them t their principles or laws.

Yet Aristotle was as little able as Plato to work ou a theory of the relation between the universal a individual reason; and the cause of this failure both cases substantially the same. In Plato's phil the ideal tended to divorce itself from the phen world in such wise that the latter was regarded suggesting or partaking in the former, but not as explicable by it. It was not merely that, to the mind individual in its progress, the veil was only graduall from the rationality of the world, but that in the there was an irrational element from which the could save itself only by flight into the region of a tion. And, though Aristotle by his doctrine of the e relation of ideas to experience, or of the develop the mind to the acquisition of knowledge of the seemed to be on the way to correct this error, yet shrinks from regarding the phenomenal world as i intelligible. To him also an irrational matter mingl things, and is in them a source of contingency and fection. Chance is not merely the reflexion upon th of our imperfect knowledge, but a fact of experien there is therefore a region in which our best science rise above generality to universality. In this wa remains for Aristotle an absolute *a posteriori*, a reality cannot be understood, and which we can scarcely c as existing at all for the divine intelligence. At th the Aristotelian philosophy appears to stand betwe alternatives, either that, in the sense of pantheism, th world and its contingency is an illusion, or that it tingent only for the growing intelligence of man fully understands neither itself nor the world whic object. Aristotle, however, does not choose either

emma, and leaves us therefore with an unresolved
between thought and its object; and this again
rily involves a dualism between the active reason,
as he asserts, realizes itself in man, and the passive
which constitutes his nature as a finite being.

he Middle Ages the Platonic and Aristotelian idea
e apprehension of objective truth is one with the
on of the mind to self-consciousness seemed to be
lost. Knowledge of the finite world was regarded
fferent, and knowledge of the infinite was conceived
omething given on authority, and in reference to
the mind was confined to an attitude of pas-ive
on or implicit faith. No greater slavery of the
an be conceived than that in which even the
of religion and morality the truths that regard the
life of the spirit itself were taken as a lesson
learned by rote from the lips of a teacher. Yet
sciousness that such truth, if it was to be received
mind, still more if it was to transform the mind,
ot be entirely foreign to it, found a voice in the
ic philosophy. And the compromise or truce
faith and reason expressed in the saying of Anselm
intelligam, according to which reason was to
itself to the analysis and demonstration of the data
l in implicit faith from the church, prepared the
the recognition that the two are not essentially
ance. The mind that proceeds from *credatio* to
o, from awe and submission to the doctrine to
ent and appreciation of it, must already in its awe
bmission have the beginnings of an intelligent
ation. Anselm's saying might be understood simply
ning that we must have spiritual experience ere
understand the things of the spirit. And in this
was adopted by the Reformers to express an idea
the opposite of that with which the scholastics
ociated it, the idea that the direct apprehension of
l truth as entering into the inner life of the subject,
tified with his very consciousness of self, is the basis
nowledge of it. In the Protestant church of the
after the Reformation, we find a growing tendency
on the subjectivity of religion, in the same exclusive
e sided way in which the mediæval church had
on its objectivity. In some extreme representa
f Protestantism this went so far as to lead to a
rd, almost to a rejection, of all objective doctrine,
eduction of theology to an account of the religious
nsness. On the other hand, while religion was thus
bjective, science claimed to be purely objective.
followers of Bacon seemed to adopt towards nature
e attitude of passive receptivity which the mediæval
n was taught to hold towards the church. While
s to learn everything from himself in religion, he
learn nothing from himself in science. His aim
e to exclude subjective *idola*, in other words, to
the facts as they were given, and keep himself out of
y. The inevitable result of this difference of view
the nature of knowledge in these two different
was, however, on the one hand a withdrawal of
from all connexion with finite interests, and,
lly from the attempt to connect religious principles
e knowledge of the finite world, and, on the other
an increasing tendency in those who represented
science to regard religion as something merely
ive and even individual, as a feeling which could
translated into thought or made the basis of any
dge of the objective world.

opposite principles of certitude which were thus
for religious truth and truth of science need only
brought together and contrasted to betray that they
on opposite abstractions, neither of which expresses
the complete nature of truth or knowledge. On
hand the truths of religion were maintained just
they were not, or were not merely, objective, but
capable of being tested by inner experience, and ide
with the self-consciousness of the individual. On th
hand the truths of science were maintained becaus
were not, or were not merely, subjective, but were
of being verified in objective experience. It was
on the one side that mere subjective feeli
opinions have no validity for any one but the sub
them, and on the other side that what is merely ob
or externally given can have permanent value and
for the intelligence only as it ceases to be mere i
and unrelated fact nay, that, even when scien
discovered law and order in nature, it still wan
highest value and interest so long as that law and or
not seen as standing in essential relation to the intel
itself. The idea of truth or knowledge as that whic
once objective and subjective, as the unity of things w
mind that knows them, enables us to understand th
demnation which the religious mind passed upon a
external dogma, and even its lack of interest in a
which presented itself as an account of merely objec
external facts. And it enables us also to understa
way in which scientific men insisted upon objecti
as the basis of all knowledge, and the disrespect
they felt for a religion which seemed to admit that
no such support. What is wanted to clear up the co
on both sides is the growth of the perception
scientific men that the objectivity which they are s
cannot be mere objectivity (which would be unme
but an objectivity that stands in essential relation
intelligence, and, on the other hand, the growth
perception among religious men that the bjecti
religion only means that God, who is the objective p
by whom things are, and are known, is spiritual, a
therefore be revealed to the spirit. When these t
rections have been made, it must become obvious t
religious consciousness is not the consciousness of a
object than that which is present in finite experien
science, but simply a higher way of knowing th
object. And in this it is also involved that the tw
of *a priori* and *a posteriori*, of that which is evolv
within and that which is given from without, a
essentially opposed to each other, but that the *a pr*
is simply the first form of a consciousness which
ultimate development must become *a priori*.

In that philosophy of compromise which was i
by Descartes, one part of knowledge was regarded as
or developed from within, and another part as em
or imparted from without. In the second period
history of modern philosophy this compromise was
and the names of Locke and Leibnitz – though wit
hesitation on both sides – represent respectively the
that all knowledge is *a posteriori* and that all kn
is *a priori*. The compromise seemed to be renew
Kant, but the form in which it was renewed p
has been already shown, to something more than
promise, for his doctrine was that the *a posteriori*
the facts, exist for us only under *a priori* conditi
in other words, that what is usually called *a po*
is in part *a priori*. The criticism of this view ne
be repeated. It is sufficient here to say that it, a
shows, the elements are inseparable or organically
it is impossible to allege that so much belongs to
and so much to the other. Furthermore, the consci
of an essential difference in the elements of know
possible only so far as that difference is transcended
unity of knowledge. We can distinguish the *a pri*
the *a posteriori* only on condition that we can tra

inction, and this means that the distinction itself absolute, but that there is a point of view from he *a posteriori* may be regarded as *a priori*, and hich is given from without to the spirit may be l to its own self-determined development.

it is just here that we come upon the turning-point philosophical controversy, in the form which it has n modern times. The problem may be expressed In what sense can we apply the idea of development human spirit? Are we to treat that development ly a determination from without, or as an evolution ithin, or as partly the one and partly the other? nse all writers of the present day would admit that st is the case. For, on the one hand, even the ian theory accounts for development by aid of e may call the *a priori* tendency of the individual ntain itself in the struggle for existence, though it es that the condition medium in which the indi- is placed determines the direction in which that ment proceeds. And, on the other hand, no one ould adopt the Leibnitzian theory that the indi- is a monad, whose self development is entirely con- d by itself in such a sense that all the relations it has to other existences are merely apparent, and e coincidence of its life with the life of the world is ult of a pre-established harmony. On both sides, re, the idea of self-determination would be admitted, the tendency of the Darwinians would be to regard lf-determination as something merely formal; and h sides it would also be admitted that the self- ination does not exclude a determination from with- ough extreme opponents of Darwin might be inclined ce this determination to a mere stimulus or external on of the development of the nature of the subject ch the stimulus is applied. The question, however, s whether, after all, this opposition of without and is an absolute one, or whether there is any point of rom which it may be transcended. To Aristotle it l possible to answer this question in the affirmative, e conceived that the reason of man is a pure or ὄϑραυς, the evolution of which to complete self- ness is one with the process whereby the objective comes to be known. Yet, as Aristotle admitted the ce in the world of a material principle which was ially different from the ideal principle of reason, he bliged to limit his statement as to the possible unity subjective and the objective consciousness, and to rely that "in things *without matter* the knower is al with the known." But this would immediately e conclusion that the pure development of reason be secured by abstraction from all finite and material s, rather than by a thorough comprehension of them. reedom of the spirit, on this theory, must be a negative ot a positive freedom, a freedom won, not by over g the world, but by withdrawing ourselves from its nce. It remained, therefore, for modern philosophy rk out the Aristotelian idea that the rational being h, in spite of its necessary relation to and depend on an external world, is never in an absolute sense nally determined. And, as we have already seen, the an philosophy brought this problem within the reach lution, in so far as it showed, first, that objective nce can have no meaning except existence for a ng self, and, secondly, that existence for a thinking eans existence the consciousness of which is "capable ng combined with the consciousness of se Add r to these propositions what was shown by Kant's ssors, that that only can be combined with the con- ness of self which is essentially related to it, and we at an idealistic theory of the world, which enables us at once to understand the relative value of the di tion between self-determination and determination without, and at the same time to see that its value is relative. If it be true that nothing exists which is possible object of consciousness, and again that there possible object of consciousness which is not essen related to self consciousness, then the phenomena external world, which at first present themselves und aspect of contingent facts, must be capable of being mately recognized as the manifestation of reason; an history of the conscious being in his relations with world is not a struggle between two independen unrelated forces, but the evolution by antagonism spiritual principle. It is, on this view, the same life within us is striving for development, and which w ns conditions that development. And the reason wh two terms, the self and the not self, thus appear independent of each other, or to be brought togethe as they externally act or react upon each other, lies i that the object is imperfectly known, and the sub imperfectly self-conscious. This, however, does not m less true that in self-consciousness is to be found th ciple in reference to which the whole process m explained, and therefore that the self conscious subj such, lives a life which belongs to him, not merely object among others, but as having in himself the pr from which the life and being of all proceeds.

From this point of view, as has been already ind the relative value of a theory of human developmen as that which might be based on the ideas of D would not be denied. The conscious being may be re simply as an externally determined object, and the inc ness of this assumption will not entirely destroy the of the results attained, especially if, as is often th with those who seek to construct a natural science o the assumption itself is not very strictly adhered corrected by the tacit admission of other conceptions what inconsistent with it. But, at the same time, it require to be pointed out that such a science is nece abstract and imperfect, as it omits from its vie central fact in the life of the object of which it trea can do nothing to account for man's consciousness, capacity of becoming conscious, of the influences by he is supposed to be determined; or, to put it fr other side, it takes for granted that the objec influence man are intelligible objects, "capable of combined with the consciousness of self," without how much is involved in this assumption. Nov evident that the consciousness of an influence can explained by the influence itself, nor even by that together with the nature of the sensitive beings su to it. It is evident also that an influence media consciousness is not, strictly speaking, an external in but that it is already transformed, and in process of further transformed, by the development of the which it is present. For the dawn of consciousn which the external object first comes into existence as opposed to the self, is at the same time the beg of the process by which its externality is negated come. Self-consciousness is that which makes viduals in a sense in which individuality can be pre of none but a self conscious being. For, in deter himself as a self, the individual at the same time e from himself every other thing and being, and dete them as external objects. He emancipates himse the world at the same time that he repels the worl himself. Yet this movement of thought, by wh individuality is constituted, is also that by which he above mere individuality, for, in becoming conscious and not-self in their opposition and relation, he ce

ly identified with the one to the exclusion of the His finite individuality is regarded by him from a al point of view, in which it has no less and no more ance than any other individuality, or in which its or less importance is determined only by its place whole. On this universality of consciousness rests sibility of science and of morality. For all science a contemplation of the world *in ordine ad universum* *in ordine ad individuum*; and all morality is just with a view to an interest which belongs to the not as this individual, but as a member of a greater and ultimately of the absolute, whole in which all d all things are included.

his nature of the conscious subject lies also the lity of metaphysic in the sense of Aristotle, as that which goes back to a *πρῶτον φύσει*, a beginning is prior to the existence in consciousness of the nal self, and onward to an end in which the divisions finite consciousness are transcended, as including, t, ontology, or metaphysic in the narrower sense, on e side, and theology, or the philosophy of religion, other. In truth, these two extremes of science are rily bound together: we can only go back to the ing if we can go on to the end; we can only recover t unity if we can anticipate the last. Or, to free ject more definitely from the associations of time, not apprehend the unity which is involved or pre- d in all the differences of our conscious life except ar as we can look at our individual existence from nt of view of the whole to which it belongs. This come evident if we consider the nature of the limits have to be transcended by such a science. The ual conscious subject, as he finds himself at first, one being in a world that stretches out, apparently t limits, on every side of him. Of the things by he is immediately surrounded he sees but a small ad the influences which he receives from them are, nows, like the wave that breaks upon a shore from known ocean, only the last partial expression of es that come from regions beyond his ken. Again, s himself as one in a changing series of beings, of he knows only the last preceding terms, and he is hat in a few years he, as one of this series, will o be. He is thus to himself a definitely limited and though his knowledge of himself and his world gradually widened so as to reach some little way nto the past, and anticipate a little of the future, or o outwards in space to embrace a widening circle of ces around him, yet he always stops at a limit, of he is conscious that it is no absolute limit, but an arbitrary halting-place where vision grows ct and imperfect. When he reflects upon himself his point of view, he is forced to regard himself as ragment, and a fragment of an unknown whole, by his whole being is determined to be what it is. ghest knowledge seems to be but a consciousness ignorance, his highest freedom a determination by s the ultimate meaning of which is hid from him.

ar there seems to be no room for any metaphysical dge, any knowledge of ourselves and our world is other than relative and *in ordine ad individuum*. rther reflexion shows that in this very consciousness t there is implied a consciousness of that which is l limit. While we proceed from part to part, beginning urselves and our immediate surroundings, and follow- t lines of connexion that lose themselves in the dis- we are guided by a consciousness of the whole as a through which the parts are determined. Nay, it is e presence of this consciousness that makes us capable at seems the piecework of our knowledge, in which, by the aid of the principle of causality, we connect cular with particular, and so gradually extend the of light into the encompassing darkness. For principle simply means that the limited external does not sufficiently explain to us its own existen that therefore we are forced to explain it by a refer something beyond it. It means, in other words, t cannot rest in that which is not a self-bounde determined whole. The application of the categ external determination has therefore an essential re to the higher category of self-determination. The endlessness of space and time has no meaning ex opposition, yet in relation, to the true infinity of we find the type in self-conscious thought. Or, to in the Kantian form in which it is already familia the consciousness of the objective world in space an stands in essential relation to the unity of self-con ness. And if when we regard the former exclusiv are forced to view ourselves as insignificant and sighted finite beings in an infinite universe, wh regard the latter we are enabled to see that in universe there is revealed only that spiritual pr which we find also in ourselves. In this way a ne is thrown on our first consciousness of ignorance strivings of our reason after knowledge can no lo regarded as strivings after an unknown goal, but after a goal which it has prescribed for itself. The limits of our individual life are not removed, bu cease to be for us the limits of a narrow circle of de within a formless infinite. They become the limi sphere within a sphere, a sphere which is defined idea of knowledge or self consciousness itself, and i therefore, however we may wander, we are everyw home. In religious language, the sphere is not universe, but God, who is without us only as He is us, so that "by the God within we can understa God without."

Again, as this consciousness takes man beyo immediate existence, and enables him to determin relation to an absolute unity of all things in Go enables him to go back to a unity which is bel prior to that existence. For, if the individual can himself as he looks at others, and at others as he himself, *i.e.*, from a point of view which is unaffe his individuality, and in which that individuality is only what it is for impartial reason, he can have not him which binds his consciousness to his individu mere individuality; as therefore he can go beyond to apprehend the whole in which his individuality place, there is nothing to prevent him from going upon himself, and upon the conditions which are his own individual being. He is not tied to his im life, and can go below it just as he can rise above i

"O God, I think Thy thoughts after Thee," said In reading the "thoughts" written in the pl system, Kepler was discovering the meaning which is simpler and more elementary than the of man, as a cycle of mechanical relations are simp more elementary than self consciousness. Yet it true feeling that led him to connect this descent i mechanical world with God. For it is only in the same faculty which enables us to rise to the life which includes and subordinates our own that so free us from the image of our own conscious li apprehend and fix in thought the simpler relat purely physical existence. But the same faculty back upon ourselves has a still deeper manife Not only can we abstract from ourselves so as to stand the inorganic world, we can also abstract fr selves so as to understand the conditions which a

thought, and therefore to the existence, of any
e external world at all, the universal conditions of
wable and therefore also of reality. In doing so,
Hegel's metaphor, which is but an extension of
s, we are "thinking what God thought and was
the creation of the world," *i.e.*, we are thinking the
l unity presupposed in all knowledge, and therefore
bjects of knowledge the consciousness in relation
h everything is, and is known.

The Relation of Logic to Metaphysic - The ordinary
logic is based on two presuppositions which tend to
t it almost entirely from metaphysic: it is based on
supposition of an opposition, or at least a merely
l relation, between thought and its object, and again
pposition, or merely external relation, between the
method and the content or matter of thought. The
ence is regarded as dealing with an object which is
o it externally, and to which, therefore, it can be
ly if it leaves it unchanged and introduces into it
of its own. Truth, to use a well-known definition,
greement of our conceptions with their objects, and
ging about this agreement all the concessions must
he side of thought. Conformably to this view, the
es of thought must be purely analytic; *i.e.*, thought
eak up the given idea of the object into its con-
t elements, and again out of these elements it may
ose the idea in its unity, but it can add nothing and
othing away. It is like an instrument which
tely dissects a solid mass into smaller parts and
mechanically presses them together, but which
penetrates and dissolves the hard matter, still less
into a new form by bringing it into contact with
emical elements.

conception, like much of the philosophy of which
specimen, is a kind of exaggerated caricature of one
of the philosophy of Aristotle. Aristotle is the
nalytic philosopher He first laid down boundaries
continuous domain of science which Plato had first
d. Not that he ever completely lost sight of the
r continuity of the different sciences which he thus
nished His unrivalled speculative genius is shown
e more clearly than in those not unfrequent utterances
ulative insight into the unity of things different, by
as at a stroke, he makes his own landmarks and all
rks to disappear. Yet such utterances generally
y themselves, and do not alter the general analytic
f his philosophy. They are not so developed as to
stinctly the merely relative character of the divisions
stinctions which are set up, or the limits of the sphere
which they hold good. Hence it was easy for
which possessed something of Aristotle's keenness
erstanding without his speculative depth to neglect
xpressions, or to explain them away. And this
of degradation was the more rapid as the philosophy
totle soon ceased to be studied in his own writings,
came a traditionary possession of the schools. In
ay we may partly explain how logic came to be
ed by mediæval philosophy as a form of thought
could be altogether separated from the matter, and
application of which that matter could be in no way
l or changed But for such a view, indeed, it is
t to conceive how the schoolmen could have ventured
y any logical processes at all to the sacred matter of
The idea of externally adding anything to the
nce delivered to the saints was excluded by the
le of authority; and the idea of developing out of
ith anything that was not immediately contained in
not yet presented itself to any one. Hence the
s of thought seemed to be purely formal and
, and it was only on the plea of its being such that
its activity could be tolerated at all. Nor was thi
of logic at once changed by the revolt against scholas
The first philosophical exponents of the modern sc
movement, while they rejected the matter of dog
fictitious, or at least as transcending the sphere of p
knowledge, and while they substituted in its place,
object of investigation, the facts of experience, d
realize any more than the schoolmen that the for
method of knowledge could be other than analytic o
matter. Bacon, their protagonist, was above all sol
to guard against any subjective *anticipatio naturæ*;
he see that the questions which, in his theory of
he proposed that science should ask of nature ther
involved any preconceived theory regarding it. Cor
as every true scientific man must be, that the st
nature involves a constant self abnegation, a patien
distrustful course of experiment and observation,
his followers did not realize the presuppositions tha
the inquiry possible, and by which it must be guided.
less did they recognize that the separation betwe
mind and its object which they took for granted e
be a relative division, *i.e.*, a division on the bas
unity, and that therefore the self abnegation of th
in its investigation of facts cannot be an absolu
abnegation, but is only the first step on the way
discovery that the facts are intelligible, and so esse
related to the intelligence. Hence to them log
seemed a mere analytic process, the end and aim of
was understood to be that a world, existing in its
of relation to thought, should be reproduced in a r
less imperfect image *in* thought. And, when it can
suspected by a less naive philosophy of experienc
after all, certain presuppositions, not given in exp
itself, were involved in the scientific interpretatio
various expedients were devised to reduce these pres
tions in an indirect way to empirical truths,- exp
of which Mill's attempt to base the law of causalit
an *inductio per enumerationem simplicem* may be t
the type.

When we go back to Aristotle, who was the "
of logic" in the sense that he was the first who
logical method as a separate branch of science,
that his division of logic from metaphysic is by no
so definite and complete as it was made by some
successors. The verification of the highest princ
thought, the law of contradiction, is treated by him
business of metaphysic. And, though he separates t
of truth from the idea of reality, and regards the
as involving a relation of thought to a reality w
determined in itself independent of that relation,
does not regard this independence as by any means a
Truth is defined by him as a connexion or distinc
ideas which *corresponds* to a union or separation of
but does not necessarily so correspond. This de
however, holds good only in so far as things a
scientifically known, or in so far as things not ess
related are brought together κατὰ συμβεβηκός.
necessity comes in, and is apprehended by reas
case is different. For in that case we have not
an external synthesis, but an essential identity, *i.e.*,
of elements which can neither be, nor be known
from each other. In relation to the principles of
therefore, Aristotle holds that error, *i.e.*, a conne
ideas not corresponding to a connexion of things, is
sible, and that the only alternatives are knowledge
norance. Either we possess the idea or we do not po
as Aristotle otherwise expresses it, in thought we ar
in contact with the things or not in contact with
there is no third possibility. The meaning of A
becomes clearer when we remember that, according

ne intelligence, in apprehending the indivisible unity
ents in the object, is at the same time apprehending
ty of the object with itself. The mind cannot be
l in regard to that which forms a part of its con-
ess of itself. In freeing the essential conception of
ject from the contingency of matter, science has
he object from that which made it foreign to
ence, and the relation of thought to things ceases
ne of correspondence, and becomes one of identity.
legitimate inference from this view of the relation
intelligence to the intelligible world would seem
at the partial separation of thought from its object
imperfect correspondence with it is characteristic
first empirical consciousness of things, and of the
s from that consciousness to science, but that in
ted science the division ceases. The *res* of things
their *percipi*, but their *intelligi*. But, if this be
s the truth, then it can no longer be supposed that
ocess by which scientific knowledge is attained con-
mply in an analysis of the object as it is given in
iate perception. On the contrary, it must be held
our thought has to submit itself to the object, and
brought into conformity with , by a process of
on, it is equally true that in process the object
ust be changed, that it may be brought into con-
y with the principle of thought. The genesis of
, according to this view, is not merely an analysis
n facts, but a process of vital transformation by
consciousness on the one side and the object on
her are brought into unity with each other. The
ndeed, of an empty process, a process in which the
y of the mind is merely formal, is one which will
and the slightest examination. A mind without
ries, if such a thing were conceivable, would have
stions to ask in relation to the object presented to
could therefore get no answers. Those who make
ence of approaching a subject in an absolutely
ve attitude, and without any presuppositions, only
hat they are unconscious of the categories by
their thought is ruled; and they will be most
ly guided by these categories just because they
nconscious of them. The schoolmen, when
pplied their logical principles to the matter of
an dogma, did not recognize that they were doing
han analysing and bringing out early the meaning
dogma. But the effect of their work was to turn
stem of divinity into a collection of insoluble puzzles;
doctrine was a doctrine of reconciliation between
and human, infinite and finite, universal and
lar, and the principle of their method was to treat
se oppositions as absolute. In like manner it might
wn that the analysis of social phenomena which was
n the last century was inadequate and superficial,
cause of the latent assumption of individualism on
it proceeded, and that the greater success of writers
omte and Spencer does not arise merely or mainly
heir being more careful observers of the phenomena
al life, but in great part from the fact that, rather by
conscious movement of opinion than by any distinct
ysic, their minds have become possessed by more
te categories.

idea that the process of thought is merely formal,
lytic of given matter, is, however, an error that has
h underlying it. This is the truth expressed by
tle in his much misunderstood comparison of the
gence of man to a *tabula rasa*, upon which nothing
t is written, and again in his assertion—already
—that the mind is a pure δύναμις, without any
guishing quality of its own which could prevent it
apprehending the real nature of other things. In
other words, self-conscious reason is not a special th
the world, but the principle through which all thing
and are understood; and hence, as regards the distinct
things from each other, it is in the first instance u
mined and indifferent, and therefore open to be deter
in one way or another, according to the object to w
is directed. But this simply means that the con
subject, as such, is not bound to his own individualit
can regard things, nay, in a sense, must regard them
a point of view which is independent of it. This is
makes possible the self restraint and self-abnegatio
scribed to the scientific man, whose whole duty, as it i
said, is to keep himself out of the way and let the
speak, to lay aside all subjective *idola* and pre
that stand between him and the reality of things.
first sight may seem to be equivalent to the assertio
the mind ought to be in a state of simple passiv
receptivity towards objects. What is really meant
ever, is not that the intelligence should go out of it
cease to be itself, that it may know its object, but
that it should show itself in its universality, or fr
from the limits of the individual nature. The self-a
tion of science is an endeavour, so to speak, to s
object with its own eyes, but this it can do only in
as the consciousness for which the object is is the
sciousness in relation to which alone all objects a
are understood. Or, to put it in another form, th
scious self in its scientific self abnegation does no
itself up to another, and become purely passive;
gives up all activity which is not the activity
universal thought for which and through which all
are. Hence, when it has so abnegated itself, its most
constructive activity is just beginning, though, just
as the self abnegation has been real, that const
activity has become one with the self revelation
object. As, however, it is only through the const
activity of thought that there exists for us any ob
all, so it is only through its continued activity th
conception of the object is changed, till it is com
revealed and known. And this activity involves
tinuous synthesis, by which an ever wider range
is brought together in an ever more definite unity
the mind has, if we may use the expression, exhau
store of categories upon the world, and until the wo
completely revealed itself in its unity with itself an
the mind.

To combine these two ideas on the one hand that
begins in a self abnegation by which the mind re
all subjective prejudices, and thereby attains a
objective attitude, and on the other hand that this
objective attitude is not a mere attitude of recepti
one in which the mind is continually transform
object by its own categories, to see that the univ
of the mind in knowing is not mere emptiness, and
activity is synthetic just when it is most free from
suppositions extraneous to the nature of its object,
of the greatest difficulties of the student of meta
Universality at first looks so like emptiness, and a n
activity so like a merely formal activity, that i
wonder that the one should be mistaken for the

invalid, because it involves a subjective addition

if we take our stand on the former, we are com- to regard all objective experience as irrational, e it does not correspond to the pure identity of t.

Aristotle's view of logic it cannot be said that this ty is clearly solved, though he seems to have seen ror of both extremes. On the one hand he often izes the synthetic character of the process of induc- s when he speaks of the universal idea or law as a principle, in which we must find the key to all the ties suggested by different aspects of a given subject. other places we trace the influence of a merely ana nception of that process as a process in which the sal is to be reached by abstracting from the peculi of individuals. And this conception of it is favoured stotle's metaphysical theory, according to which the of things in the finite world are manifested in a g matter, a matter which prevents them from being ly or universally realized. For, in so far as this is e, the facts will not be entirely explained by the dge of the form, and the knowledge of the form e obtained, not by combining all the facts, but rather racting from them. Again, in Aristotle's account process of thought in the *Prior Analytics*, he it as a formal deductive process, and, though *Posterior Analytics* he attempts to give a synthetic g to the syllogism by treating it as the method in the properties of a thing may be proved of it, or ed with it, through its essential definition, yet this tions meaning bestowed upon the syllogistic process t alter its essential nature. The ultimate source of adequate view of the process of thought seems to lie totle's imperfect conception of the unity or identity s for him the type of knowledge. For, though, both *Metaphysic* and the *De Anima*, he defines that identity consciousness or as a consciousness of objects which tical with self-consciousness, yet he does not seem to distinguish between a unity in which there is no ce and a unity in which difference is transcended and ed. This seems to be shown by his description of the es which reason apprehends as *individua* or indi unities, rather than unities which imply, while they nd, difference. Yet, in this definition of the unity wledge as self-consciousness, Aristotle has implicitly ed that there is a duality or difference in the unity and this might have been expected to modify his ion of the relation of consciousness to its objects. self-consciousness is not simple like a chemical , but only in the sense that it is an indissoluble of opposites, it might have been anticipated that o had realized self consciousness as the principle owledge would be able to regard the opposition n the consciousness of self and the consciousness of rld as itself also capable of being conceived as a

misconception of Aristotle may be shown in way. In the *Metaphysic* we find him laying down s called the logical law of contradiction as the e principle of knowledge. The meaning of this le, however, as Aristotle states it, is simply that t in its essence is definition or distinction. If, as tus says, everything at once is and is not, if we attach any definite predicates to things by which ay be distinguished from each other, then, as le argues, thought is chaos, and knowledge is ble. If determination be not negation, if the n of A be not the negation of not-A, then there is ning in words. The criticism to be made on this obviously, not that it is a false statement of the law ght, but that it is an imperfect statement of it. Thought is undoubtedly distinction; and, if all dist be confounded, no meaning can be apprehended pressed. But thought is also relation and conne the things distinguished, and this aspect of it is important with the other. Aristotle shows his on ness—a one-sidedness which throws him into opp to Plato, but which enables him to correct Plato falling into the opposite error- when he exclusive his attention on the "differentiating" aspect of kno and takes no notice of the "integrating" aspect of is easy to see that this exclusive attention to one the truth may lead in many ways to a distorted vie of the world and of the intelligence that apprehends Heraclitus be interpreted as simply denying the thought to introduce its definiteness into the flux o nothing but absolute scepticism can come out philosophy; and Aristotle was right in maintaining t only as the flux is brought to a stand, and the univ fixed as a permanent and definite object of though knowledge becomes possible. But, on the other h distinction be taken as absolute, if the definite a of a thing be taken as a negation of all relation to is not, if the fixity of thought be taken as an abstra identity which excludes all the movement of finite wherein they show their finitude and pass beyon selves into other things, then knowledge will be impossible. Our consciousness, on such a theory, be disintegrated into parts which would own no co with each other; nor would it be possible for us t of things as, in spite of their differences, bound toget the unity of one world. The law of contradic distinction, therefore, is likely to lead to serious ceptions, unless it be complemented by a law of rel a law expressing the truth that there is a unity transcends all distinction. For all intelligible dis all distinction of things in the intelligible world be subordinate to their unity as belonging to that and therefore essentially connected with each oth with the intelligence. In such a world, in other there can be no absolute distinctions or differenc even between being and not-being); for distinction relation is impossible, and a conception held in a isolation from all correlated conceptions ceases t any meaning. This does not, of course, imply a n of the law of contradiction within its own sphere, does imply that that sphere is limited, and that the absolute contradiction. All opposition is within supposed unity, and therefore points to a higher rec tion, a reconciliation which is reached when we sh the opposition is one of correlative elements.

The great step in logical theory which was taken idealistic philosophy of the post-Kantian period was to dissipate the confusion which had prevailed between that bare or formal identity, which is beginning of thought and knowledge, and that unity of difference, which is its highest idea and e was, in other words, to correct and complete the tions of thought as analytical, and as externally sy cal, by the conception of it as self-determining, that it is a unity which manifests itself in differen opposition, yet in all this, even when it seems dealing with an object which is altogether exte it, is really developing and revealing itself. Th movement of thought might, in one point of v described as the addition of another logic to th of analysis and the logic of inductive synthesis were already in existence. But it was really mo this; for the new logic was not merely an external a

[1] ἠρεμήσαντος τοῦ καθόλου ἐν τῇ ψυχῇ, *An. Post.*, ii.

old logics, it also put a new meaning into these y bringing to light the principles that were involved . At the same time it broke down the division d been supposed to exist between logic and meta- between the form or method of thought and its It showed that thought itself contains a matter hich it cannot be separated, and that it is only by of this matter that it is able to ask intelligent ns of nature, and to get from nature intelligible . A short space must be devoted to explain this of the three logics to each other.

analytic logic fairly represents our first scientific e to the world, in which we concentrate our attention he facts as they are given in experience, with no t of any mental synthesis through which they are To ourselves we seem to have to do with an object s altogether independent of our thought, and what d in order to know it is to keep ourselves in a purely ve attitude. All we can do is to analyse what is without adding anything of our own to it. It has, r, already been pointed out that this apparent self- tion is possible only because, in abnegating our indi- point of view, we do not abnegate the point of view longs to us as universal or thinking subjects. In words, the objectivity of knowledge thus attained is ceasing of the activity of our thought, but rather of interferes with that activity. We seem to abstract urselves, but what we do abstract from is only the uality that stands between us and the world. The ic observer who has thus denied himself, however, necessarily conscious of the meaning of what he has The immediate expression of his consciousness is think the object," but "it, the object, is"; and the tensely active he is the more his activity is lost for the object of it. His whole work is, for himself, e analysis of given facts, and for the rest he seems nothing to do but to take the world as he finds he voice of nature to which he listens is for him own voice but the voice of a stranger, and it does ur to him to reflect that nature could not speak to but a conscious self. His business is to determine as they present themselves, to enumerate their es, to measure their quantities; and his logic accord- a logic governed by the idea of the relative com- sion and extension of the things which he thus and classifies. Such an analytic logic seems to be is necessary, because the only predicates by which are as yet determined are those which are involved r presence to us in perception, and as perceived they be at once given in all their reality to the mind prehends them.

ep is taken beyond this first naive consciousness of whenever a distinction is made between appearance ality, or whenever it is seen that the things perceived entially related to each other, and that therefore they be known by their immediate presence to sense, but a mind which relates that which is, to that which immediately perceived. If "the shows of things are hemselves," we must go beyond the shows in order to them; we must seek out the permanent for that is given as transient, the law for the phenomenon, se for the effect. The process of thought in know- herefore is no longer lost in its immediate object, partly at least, distinguished from it. For just in tion as the reality is separated from the appearance e knower become conscious of an activity of his own t in determining things. From this point of view is no longer an object which spontaneously reveals o us, but rather one which hides its meaning from l out of which we must wring its secret by persistent questioning. And, as this questioning process ob has not its direction determined purely by the object it becomes manifest that the mind must bring with categories by which it seeks to make nature intel To ask for the causes of things, or the laws of thing supposes that the immediate appearance of them d correspond to an idea of reality which the mind with it, and by which it judges the appearance. is supposed to be given to or perceived by us as a tude of objects in space passing through successive in time; and what science seeks is to discover a n of connexion running through all this apparently cont coexistence and succession and binding it into a s Science, therefore, seems to question nature by m an idea of the necessary interdependence and conne all things, as parts of one systematic whole gover general laws- an idea which it does not get from but which it brings to nature. Hence the logic in this process of investigation expresses its conscious itself will be a synthetic logic, a logic built on certai ciples which are conceived to be independent of expe and by the aid of which we may so transform that ence, so penetrate into it or get beyond it, as to find a better explanation than that which it immediately g itself. The *Posterior Analytic*, in which Aristotle br the idea of cause to vivify the syllogistic process, or s real meaning to it, may already be regarded as a firs in this direction. And the theory of inductive l explained by Bacon and his successors down to M continuous attempt to determine what are the princip methods on which experience must be questioned, i to extract from it a knowledge which is not given mediate perception.

It was, however, Hume who first brought into light the subjectivity of the principles postulated logic, and especially of the principle of causality, w the most important of them. In thus contrasting t jectivity of the principles of science with the obj of the facts to which they are applied, it was his in to cast doubt on the science which is based on the tion of the former to the latter. The principles, h tains, are not legitimately derived from the facts, th they cannot legitimately be used to interpret them. are due to the influence of habit, which by an illeg process raises frequency of occurrence into the univ and necessity of law, and so changes a mere sub association of ideas into an assured belief and expe of objective facts. The answer given by Kant sceptical criticism of science involved a rejection very opposition of subjective and objective upon w was based. Without necessary and universal pri the experience of things as qualitatively and quanti determined objects, coexisting in space and through changes in time (or even the determinatio successive states of the subject as successive), wou have been impossible. Hence necessity of thought be derived from a frequent experience of such obje is true that the determination of things as permane stances reciprocally acting on each other, according versal laws, goes beyond the determination of t qualified and quantified phenomena in space an But both determinations are possible only throu same *a priori* principle, and we cannot admit the determination without implicitly admitting the latte therefore, it is through the necessity and univers thought that objects exist for us, even before the app to them of the principles of scientific induction, an application of those principles is only a further that *a priori* synthesis which is already involved perception of these objects, we have no reason for

mer kind of synthesis as objectively valid which
t equally apply to the latter.
vindication of the principles of induction has, how-
further consequence, which was not clearly seen by
It is fatal to the antithesis of the "given" and
nown," of what is perceived and what is conceived,
ura materialiter spectata and *natura formaliter*
, which he still admitted. For that antithesis
rested on the idea that there is no universal and
ry principle of determination of things involved in
prehension of them as qualified and quantified
nena in space and time. So soon, therefore, as it is
at there is such a principle, and that the first deter
n of things as objects of perception is due to the
priori synthesis which determines them in the
place as objects of experience, the ground for that
t between reality and appearance on which the
of induction rested is taken away. Kant, indeed,
new meaning for that contrast by interpreting it as
g, not to the opposition between things as they are
nd things as they are known, but to a supposed
ion between things as they are given and known in
nce and things as they are in themselves out of
nce. This new antithesis of reality and appearance,
r, only means that the former antithesis has broken
and that therefore the ideal of knowledge based
has yielded to a new ideal. The so-called things
selves are noumena, the objects of an intuitive or
ive understanding, *i.e.*, objects in which the contrast
ption and conception, of given and known, is tran
l. We can make Kant's theory consistent only by
ng him to mean that the conception of the world as
n of substances determining each other according
ersal laws does not yet satisfy the idea of know-
hich reason brings with it. In other words, just
nce from the point of view of necessary law found
ng wanting in the conception of the world as a
omplex of quantified and qualified phenomena in
nd time, so philosophy, in view of a still higher ideal
wledge, may condemn the conception of the world
stem of objects determined by necessary laws of
as itself inadequate and imperfect. And we have
at this higher ideal is that which is involved in
ity of self consciousness. Unfortunately Kant was
as Aristotle had been unable, to distinguish this
m the idea of an abstract identity in which there
om for even a relative difference of perception and
ion, and therefore the perceptive understanding was
by him only to be rejected.
owever, we correct this inadequacy of Kant's state-
as his later works enable us partly to correct it,
that it involves a new idea of knowledge and a new
-a logic governed by the idea of organic unity and
ment, just as the analytic logic had been governed
idea of identity, and as the inductive logic had been
ed by the idea of necessary law. For, if the unity
consciousness be our type of knowledge, truth must
o us, not the apprehension of objects as self identical
distinguished from each other in quantity and
, nor even the determination of such things as
g in necessary relations to each other. It must
he determination of the world (and of whatever in
any sense an independent reality, so far as it is so
ndent) as a unity which realizes itself in and through
nce, a unity which is indeed determined, but deter-
by itself In a view of the world which is governed
s category, correlation must be reinterpreted as
unity, and causation as development. Its logical
must be neither analytical nor synthetical, or
t must be both at once, *i.e.*, it must endeavour to
exhibit the process of things as the evolution of a
which is at once self-differentiating and self-integ
which manifests itself in difference, that through dif
it may return upon itself. Further, as this logic
simply out of a deeper consciousness of that whic
contained in the two previous logics, so it first ena
to explain them. In other words, the advance fr
analytic to the inductive logic, and again from the ind
to what may be called the genetic logic, may it
shown to be a self-determined development of thou
which the first two steps are the imperfect manife
of a principle fully revealed only in the last step.
consciousness of self-identical objects, independent
other and of thought, is thus only the beginning of
cess of knowledge which reaches its second stage
determination of these objects as essentially related
other, and which finds its ultimate end in the kno
of the correlated objects as essentially related to th
that knows them. Or if, in this last point of view,
are still conceived as having a certain relative indepe
of the mind, it can only be in so far as they are
Leibnitzian sense monads, or microcosms, - *i.e.*, in se
they are self determined, and so have, in the narrowe
of their individual life, something analogous to th
completed nature of the world, when it is contempl
its unity with its spiritual principle.

Such a genetic logic is inconsistent with any al
distinction between the *a priori* and *a posteriori* e
in knowledge. For here the *a priori* is not simply
of necessary connexion to be applied to an external
but a principle of organic development, a principle
from the very nature of it, cannot be applied to a
matter. To treat the world as organic is to apply
category which is inconsistent with its being som
merely given or externally presented to thought.
relation of things to thought must itself be brought
the same category of organic unity which is applied
relation of things to each other in the world, otherw
externality of the world to the thought for which it
contradict the conception of the world as itself o
Hence the distinction of *a priori* and *a posteriori*, so
it is maintained at all, must shrink to something sec
and relative. It can be maintained only as a dist
of thought from its object, which presupposes their u
unity. From this point of view logic may be said
with the *a priori*, in so far as it treats the general con
and methods of knowledge without reference to any
cular object. Logic must exhibit abstractly the pro
which the intelligence establishes its unity with the
gible world; or, to put it in another way, it must
strate that the being of things can be truly conceive
as their being for thought. It is limited to the *a pr*
the sense that it ends with the idea that the *esse* of
is their *intelligi*, and does not consider how th
intelligence or intelligible reality manifests itself
concrete world of nature and spirit.

In this sense logic cannot be separated from meta

The Relation of Metaphysic to Philosophy of Religion.

possibility of a "first philosophy," as we have seen, is essentially bound up with the possibility t we may call a last philosophy. It is only in so we can rise above the point of view of the individual dualism of the ordinary consciousness in so far, er words, as we can have at least an anticipative usness of that last unity in which all the differences gs from each other and from the mind that knows re explained and transcended that we are able to to that first unity which all these differences pre- The life of man begins with a divided consciousith a consciousness of self which is opposed to the usness of what is not self, with a consciousness of a icity of particulars which do not seem to be bound er by any one universal principle. Such division parent independence of what are really parts of one is characteristic of nature, and in spirit it is at first far transcended that it has become conscious of A conscious difference, however, as it is a difference sciousness, is no longer an unmediated difference. difference through which the unity has begun to self, and which therefore the unity is on the way to nate. And all the development of consciousness lf-consciousness is just the process through which bordination is carried out, up to the point at which ference is seen to be nothing but the manifestation unity. Just so far, therefore, as this end is present —so far as we are able to look forward to the solution nciliation of all the divisions and oppositions of we are conscious and to see that there is an all- ing unity which they cannot destroy, is it possible e should look back to the beginning or first unity, cognize that these divisions and oppositions are but nifestations of it. Thus the extremes of abstractness concreteness of thought are bound up together. The n of intelligence by which we get rid of the complexity actual life, and direct our thoughts to the simplest ost elementary conditions of being and knowing, is e only to those who are not limited to that life, but gard it and all its finite concerns from the point of f the infinite and the universal. In this sense it is hat religion and metaphysic spring from the same and that it is possible to vindicate the rationality of only on metaphysical principles. The philosophy gion is, in fact, only the last application or final sion of metaphysic; and, conversely, a metaphysic is not capable of furnishing an explanation of religion dicts itself.

last remark affords us a kind of criterion of a true ysic. Can it or can it not explain religion? If it , it must be equally unable to explain its own possi- and therefore implicitly it condemns itself. Thus a istic system, which loses the subject in the absolute nce, cannot explain how that subject should appre- he substance of which it is but a transitory mode, nor, other hand, can it explain why the substance should st itself in and to a subject. And the same criticism made on all theories in which the first or metaphysical s abstractly opposed to the manifoldness and con- cy of things. Not only of Spinoza, but also of Kant, nte, and even of Schelling, it might with some truth d that their absolute is like the lion's den, towards all the tracks are directed, while none come from it. essential that the first unity should be such as to explain the possibility of difference and division, fo is not, then the return to unity out of difference is n accidental as the difference itself. When Aristotle sented the Divine Being as pure self-consciousness form without matter, he found himself unable to a for the existence of any world in which form was r in matter. When therefore he speaks of the proc the finite world by which it returns to God, and att to nature a will, which is directed to the good as i cause, his theory seems to be little more than a me in which the analogy of consciousness is applied unconscious. For, if the Divine Being is not man in the world, any tendency of the world to realize th becomes an inexplicable fact. A similar difficulty we saw, involved in Kant's confusion of the bare id of understanding with the absolute unity of know Reducing the unity of self-consciousness to such identity, Kant could not be expected to see, what Ar had not seen, that pure self-consciousness is esse related to anything but itself. Hence the various at which he made in his ethical works and in his *Critic Judgment* to find a link of connexion between the not and the empirical were necessarily condemned even l self as the expressions of a merely regulative and sub principle of knowledge. Even Fichte, who found thought, which is for him the *prius* of all existe principle of differentiation and integration which exp how self-consciousness in us should be necessarily corr with the consciousness of a world, was unable to fre self from the Kantian opposition of a noumenal id in which there is no difference to a phenomenal which is realized in difference. Hence by him a return out of difference is regarded as an impossibi as a *processus in infinitum*, and the absolute unity which is beyond all knowledge and only apprehen faith.

If we look to completely elaborated theories, a regard all tentative and imperfect sketches, it may be said that all that has as yet been done in the re pure metaphysic is contained in two works, in the *physic* of Aristotle and the *Logic* of Hegel. And certain point the lesson which they teach is one a same, viz., that the ultimate unity which is presu in all differences is the unity of thought with its unity of self consciousness, and that in this unity tained the type of all science, and the form of all exi in other words, I = I is the formula of the universe difference between these two works has, however, been indicated. With Aristotle, because he negle essential relation of self consciousness to conscious of the conscious self to the world of objects in sp time, the unity of self consciousness tends to pass, a pass with the Neo Platonists, into a pure identity difference. In the Hegelian logic, on the other ha consciousness is interpreted as a unity which realiz through difference and the reconciliation of differen in fact, an organic unity of elements, which exist they pass into each other. In other words, it is that the differentiating movement by which the su and the objective self are opposed and the inte movement by which they are reunited are both es Hence we cannot think of the conscious self as a resting identity, but only as an active self-deter principle; nor can we think of its self-determinati pure affirmation of itself, without any negation, b as an affirmation which involves a double negati opposition of two elements which yet are essentially Each factor in this unity, in fact, is necessarily co as passing beyond itself into the other: the sub subject only as it relates itself to the object, the o

only as it relates itself to the subject. It is this against each other of elements which yet are correand indissolubly united, this self-surrender to each of elements which yet are maintained in their distinewhich constitutes the organic unity of thought in and separates it from the mere abstract unity of ism. When, however, the concrete or self-differencharacter of the unity of self consciousness is appre in this way, so that it is impossible to confuse its ible unity with the simplicity of that which is one because it has no differences in it, the problem of ation of pure self-consciousness to the world in space ne ceases to be insoluble. Thought, as it is seen to difference in itself, is no longer irreconcilable with rld of difference; nor is it necessary to introduce a ὕλη to make their connexion intelligible. For, as t is a principle of difference as well as of unity, of is as well as of synthesis, and as it cannot realize its unity except through the utmost development rence, abstract self consciousness, with its transparent rely ideal difference, cannot be its ultimate form. contrary, the consciousness of self is possible only netion from, and in relation to, a world of objects. er words, the unity of the thinking subject pres, not merely the opposition of the subjective and ective self, but also the opposition of the self in its lf-identity to a world of externality and difference. re intelligence, which is the *prius* of all things, must nerefore, be regarded—as Aristotle regarded it—as theoretical, but also as practical. It must be con as a living principle, a principle which only in self- station can be conscious of itself, and to the very of which, therefore, self-manifestation is essential. way Hegel—just because he grasped the concrete er of the unity of thought in itself—was enabled to tand the necessary unity of thought or self-consciousith the world, and to heal the division of physics netaphysic, which Aristotle had admitted.

elling and others who have raised objections to the an method have specially directed their criticisms this transition from logic to the philosophy of from pure self-consciousness to the external world ce and time. In doing so, they have practically back upon the Aristotelian theory, with its opposition , as pure form, to the finite world. But this in effect eny that "the real is the rational" or intelligible, introduce into the world, as the ground of its tion from reason, a purely irrational or contingent t. A modern follower of Schelling's later positive phy only draws the necessary consequence from this hen he teaches the pessimist creed that the highest s the negation or extinction of the finite. Nor can nder that the same writer who denies that the te self consciousness is essentially related to or sted in the world should proceed to reduce this sciousness to a mystic identity which comes out of and becomes self-conscious only by an inscrutable will. The fact, indeed, that those who deny the lity of a rational transition from self-consciousness world are forced by the logic of their position to self-consciousness to an abstract identity may be ed as a kind of indirect proof that the principle of sciousness, truly conceived, does involve that transi- Another step in the same direction may be made if sider how the Cartesian philosophy treated the same tion, which it also regarded as absolute. By tes mind and matter, thought and extension, are as abstract opposites, every quality of each finding ntradictory counterpart in a quality of the other. s a pure self-determined unity, which is as it knows itself and knows itself as it is, which has no discre parts or capacity of division or determination from w Matter is essentially discrete or infinitely divided; pure passivity; and all its determination comes to without. The world is therefore, as it were, "cut with a hatchet," divided into two unrelated exis which are held together only by the will of God. S cuts the knot, and avoids the arbitrariness of this so by treating extension and thought as two att separated only in respect of our intelligence, bu expressing fully the absolute substance. And som like the same view has been revived in recent tir writers like Lewes and Mr Spencer, who speak of f and motions as two opposite "aspects" of the sam When we ask, however, *for whom* these attribu aspects are a unity, it becomes clear that the intel which is regarded as standing on one side of the d must also be taken as transcending it, and relating t sides to each other. Moreover, the correspondence two attributes upon which Spinoza insists and their riety upon which Descartes insists, when taken to give us the idea of a correlative opposition, *i.e.*, of an tion of elements which yet are necessary to each If, therefore, they cannot be simply identified as S identifies them, yet they need no external bond s Descartes introduces to combine them; for they exist apart from each other. Their opposition i within the limits of their unity, and is no absolu tradiction, but rather an opposition which exists on is transcended. In other words, it is an abstract tion, *i.e.*, it is an opposition of elements which seen irreconcilable till it is observed that they are corr that each exists or has a meaning only as it relate to, or passes out of itself into, the other, and tha held in its abstraction and separation from the othe all the meaning that it seemed to have. For, as organic body each member or organ lives only in against the others, yet only as continually relating i the others, so the utmost opposition of mind to ma the intelligence to the intelligible world, presuppos unity, and is only the realization of it.

There is here, however, something more than an o case of correlation, for in this unity of opposite appears twice, once as one of the opposites, and as the unity which transcends the opposition. ambiguity becomes most obvious in theories like tha Spencer, who speaks of "two consciousnesses," which be resolved into each other, but yet which strange inseparable parts of one and the same consciousness. however, is really involved in such a statement is t external world, which in the first instance presen as absolutely opposed in nature to the subject whose it is, is yet one with that subject, and that theref antagonism of mind to its object is only the last diff tion through which it realizes its unity with itse Hegel's language, that which presents itself as oth mind is *its* other—"an other which is not another," difference and opposition to itself it overreaches an comes. We must, therefore, regard the independe externality of nature, its indifference, and even, as it opposition, to the development of the moral and inte life of man, as merely apparent. For man, in th of view, is not merely one natural being among oth the being in whom nature is at once complet transcended. If, therefore, at first he appears t in merely accidental and external relations to th existences among which he finds himself, yet the process of his life—the process by which he comes t the external world, and by which, reacting upon makes it the means to the realization of an individ

life of his own—is the negation of this contingency
xternality. In all this process he is showing himself
a being who can only know himself as he knows the
ive world, and who can only realize himself as he
himself the agent of a Divine purpose, to which all
are contributing.

h an idea of man's relation to the world is necessarily
od in any theory that goes beyond that subjective
m, or sensationalism which denies to him every
of knowledge except his own states of feeling, and
end of action except his own pleasures and pains.
t speculation, indeed, has suggested a compromise by
this dilemma is supposed to be evaded, and mankind
presented as forming an organic unity in themselves,
h they are still conceived as standing in an external
ccidental relation to nature, the forces of which by
knowledge and skill they have subdued and are more
ore subduing to their service. Such a compromise
d in the philosophy of Comte, the first writer who,
g from an apparently empirical basis, was able to
through the individualistic prejudices of the school of
. In the latter volumes of his *Positive Philosophy*,
ore in his *Positive Politics*, Comte so far transcends
dualism as to deny the externality of men to each
and to declare that "the individual, as such, is an
ction," and that in reality he cannot be separated
the social organism, which is thus not merely an
eous condition of his development, but essential to
ry existence as man. Thus individual men exist
hrough the universal—through the spirit of the
, of the nation, of humanity, which manifests itself
m as a principle of life and development. Yet this
e unity, according to Comte, is in contact with a
which in relation to it is external and contingent.
e has not its final cause in man, but on the contrary is,
, rather his enemy; and it is to humanity itself that
aise is due if to a certain extent the enemy has been
into a servant. The unity of life which manifests
in humanity cannot therefore be considered as a
sal principle, as the principle of the whole universe,
nply as the principle of the limited existence of man,
is hemmed in on every side by external and, in the
unknown conditions. If humanity therefore is an
sm, it is an organism existing in a medium which in
ce to it is inorganic, *i.e.*, in a medium which has no
al relation to the life which animates man.

s obvious, however, that this theory is an illogical
t to find a standing ground between two opposite
phies,—between the philosophy which treats man
as a natural individual, placed among other individual
and things, and which therefore regards his relation
n as something accidental and external, and the philo-
which treats him as a spiritual subject, a conscious
f-conscious being, and regards him therefore as having
ely external relations either to other men or to nature.
shrinks from regarding the world without us as the
station of that spiritual principle which is also within
ich constitutes our very nature as individual men,
erefore connects us with the world at the same time
t separates us from it. Yet he recognizes the
ce in us of a principle which is so far universal that
titutes a community between all men. He thinks
e individual can transcend himself, so far as to see
ngs, not indeed from a Divine point of view, *sub
eternitatis*, but from the point of view of universal
ity, and that in conformity with this theoretical
ousness, he can live a practical life of altruism, *i.e.*,
n which he identifies his own good with the good of
ity. But the philosophy that has gone so far must
ly go further. It is impossible to treat humanity as
an organism without extending the organic idea to t
ditions under which the social life of humanity is dev
The medium by aid of which, or in reacting
which, the organized being maintains itself is an e
part of its life; it remains organic only in so far a
mould itself to its conditions, and its conditions t
This is true even of the animal organism in relatio
small circle of conditions, which, however, is pa
larger circle to which the animal has no relation.
conscious being is a *universal* centre of relations;
nothing which it, as conscious, cannot make part of
life. Hence the application of the organic idea t
volves its application to the whole world. And,
recognition of a universal principle manifested in hu
naturally led Comte to the idea of the worship of hu
the recognition of a universal principle manifested
and nature alike must lead to the idea of the wo
God.

The rationality of religion, then, rests on the pos
of an ultimate synthesis in which man and natu
regarded as the manifestation of one spiritual pr
For religion involves a faith that, in our efforts to
the good of humanity, we are not merely straining
an ideal beyond us, which may or may not be realiz
are animated by a principle which within us and w
us is necessarily realizing itself, because it is the n
principle by which all things are, and are known.
absolute certitude that we work effectually because
universe is working with us, or, in other words, t
God is working in us, can find its explanation and
only in a philosophy for which "the real is the ra
and the rational is the real." And such a philo
beginning with the Kantian doctrine that existence
existence for a spiritual or thinking subject, must
to prove that that only can exist for such a subject
is the manifestation of thought or spirit; and, conv
that spirit or intelligence is essentially self-manifesti
in other words, that it cannot be conceived exc
standing in essential relation to an external and n
world. Finally, if nature be thus regarded as a ne
manifestation of spirit, it can be opposed to spirit
so far as spirit in its realization becomes opposed t
In other words, nature must be regarded as, from a
point of view, included in spirit. Nature exists
may show itself to be spiritual in and to man
transcends it yet implies it, who finds in it the ne
basis of his thought and action, but only that he ma
upon it a higher spiritual life.

> Nature is made better by no mean
> But nature makes that mean: so over the art
> Which, you say, adds to nature is an art
> Which nature makes."

Only the order of precedence suggested by these
must be inverted. For, as nature only is for sp
the spiritual energy which reacts upon nature
which manifests for the first time what nature in
is. It is the consciousness of this—*i.e.*, of the iden
that which is realizing itself within and without u
consciousness that the necessity which is the preco
of our freedom is the manifestation of the same
which makes us free—which turns morality into r

of the highest ends of human life as no mere happy ac
or as a conquest to be won by the cunning of man f
unfriendly or indifferent destiny, but as the result t
which all things are working.

In this philosophy, which finds its most ad
expression in the works of Hegel, there are two
which may be distinguished the general idealistic
the world, and the dialectical movement of thou

Hegel develops and expresses it. And there are
s many at the present time who are prepared to
the former, but who yet suspect, or even reject, the
And no doubt there is much in Hegel's *Logic* and
ophy of Spirit, and still more in his *Philosophy of*
r, which there is reason to regard with distrust.
ver hands that are not checked by a sufficient con-
ness of the whole, the Hegelian dialectic may be
into the means of producing a seeming proof of any-
Nor is it always easy to determine how far Hegel
f was tempted by an impatient consciousness of the
sality of his method to employ it in cases where the
ions of its successful application were wanting.
imes he seems to forget, what he himself teaches, that
must first have generalized experience and deter-
it by its finite categories, ere it is possible for
ophy to give its final interpretation. Yet, when we
the nature of that interpretation, and of the trans-
ion of science which philosophy by means of it
es to effect, it becomes clear that the dialectic of
is no extraneous addition to his idealism, but is part
arcel of the same movement of thought. For this
ic rests on the idea that thought or self-conscious
nds in its own organic unity the ultimate key to all
lties in regard to the objects of thought and their
ns to each other and to the mind. Self-consciousness,
been already shown, is implicitly the whole web
gories which it throws over the world, and by aid
ich it makes the world intelligible. All these it
ns in itself; and, as it proceeds to determine the
ng of things, it simply produces its store, and
sts itself on the object. Now, if it be idealism, in the
sense of the word, to make thought or self conscious-
the principle and ultimate explanation of all that
it is obvious that we cannot separate idealism from
dialectic as this, which is nothing more than the
consciousness of its own movement or process of
firmation. If to find thought in things be more than
npty word, then the movement or process which
ht is must explain at once the transition from
ht to what in opposition to it we call "things," and
give us the means of reconciling that opposition. In
words, the same movement by which thought deter-
itself as self conscious, *i.e.*, as a unity realized through
nce, must also be conceived as the explanation of the
nce between pure thought and the world, and as the
n of that difference in the idea of absolute spirit.
h idealism has a close relation to Christianity; it may
n said to be but Christianity theorized. It has often
sserted that Hegel's philosophy of religion is but an
ial accommodation to Christian doctrine of a philo-
which has no inherent relation to Christianity. If,
e, we regard the actual development of that philo-
it would be truer to say that it was the study of
tian ideas which first produced it. What delivered
from the mysticism in which the later philosophies
hte and Schelling tended to lose themselves, and led
in his own language, to regard the absolute "not
y as substance but as subject,"—what made him
nize with Fichte that the absolute principle is spiritual,
et enabled him with Schelling to see in nature, as
posite of spirit, the very means of its realization,—
is thorough appreciation of the ethical and religious
ng of Christianity. In the great Christian aphorism
"he who loseth his life alone can save it" he found
to the difficulties of ethics, a reconciliation of
ism and asceticism. For what this saying implies
a spiritual or self-conscious being is one who is in
diction with himself when he makes his individual
is end. In opposing his own interest to that of

all things are his, and his only, who has died to h
But if this be the truth of morality, it is something
for "morality is the nature of things." We cannot se
the law of the life of man from the law of the w
which he lives. And, if it is the nature of things,
the nature of spirit, that he who loseth his life shal
it, the world must be referred to a spiritual princip
the Christian doctrine of the nature of God is on
converse of the Christian law of ethics. To Hegel, st
from this point, a new light was thrown on the Fi
treatment of the idea of self, and the Fichtean proof t
consciousness of self implies a relation to an object
is opposed to the self, and which yet from another
of view —since an object exists only for a subject—
be anything but an element of its own life. It wa
that this movement of thought is no mere fluct
between contradictory positions, to be terminated fin
an *ipse dixit* of faith, but that the unity of the o
elements is apprehensible by the intelligence, an
indeed it is *its* presence to the intelligence which
the consciousness of opposition possible. It was
sense that Hegel could say that that unity of op
which had been called unintelligible by previous
was just the very nature of the intelligence, and tha
a view of the world guided by this idea could be pr
intelligible, while every other view must contain
an unsolved contradiction, an element that remain
manently impervious to thought.

The great objection to a metaphysic like this, a
an objection which weighs much in the minds of
is that which springs from the contrast between th
of absolute knowledge which it seems to involve a
actual limitations which our intelligence encount
every direction. If the theory were true, it is
ought to be nearer the solution of the problems
life, practical and speculative, than we are; the ri
the painful earth ought to vex us less; we ou
find our way more easily through the entanglem
facts, and to be able to deal with practical difficulti
less tentative manner. Yet there is really no anta
between such a doctrine and a consciousness of the
tion of our faculties; nay rather, it is only on
theory that a rational distrust of ourselves can be
When Aristotle meets the warning that we should
finite and human things since we are finite and
with the answer that we ought rather, so far as in
to rise to what is immortal and divine, he is not d
the limits of man's knowledge and power; on the co
he is rather pointing to the very principle which m
conscious of those limits; for it is just because the
man a principle of infinity that he knows his finitud

yet conscious that he is trembling before himself.
truth is often expressed by Kant with special rela
the moral consciousness, as where he contrasts the lim
of man, as a sensible being, occupying an infinitesime
in the boundless world of sense, with his freedom f
limitation as a personal self, a member of the truly
world of intelligence. But it is not necessary to
Kant's abstract division of the sensible from the inte
world to see that the consciousness of the greatness
problem which has to be solved in human life and t
is deepened and widened by that very idea of phil
which yet gives us the assurance that the prob
not insoluble, and even that, in principle, it is
solved.

TAPONTUM, or METAPONTIUM (the first form is that
y found in Latin writers, but Thucydides, Strabo,
er Greek authors employ the latter form), was a
Magna Græcia situated on the Gulf of Tarentum,
e mouth of the river Bradanus, and distant about
s from Tarentum and 14 from Heraclea. It was
l by an Achæan colony about 700 B.C., though
traditions existed which assigned it an earlier
But according to the only historical account it
joint foundation from Sybaris and Crotona, to
as usual in similar cases, was joined a body of fresh
from the mother country, under the command of a
named Leucippus. The object of its establishment
hout doubt to strengthen the Achæan element in
Græcia, as opposed to the increasing power of the
nes, but at the same time to occupy a territory
was remarkable for its fertility. It was to this
hat Metapontum owed the great prosperity to which
ed at an early period, and appears to have continued
for several centuries, though it never assumed a
ent place in history. It was, however, one of the

there in the time of Cicero.

the time of the Athenian expedition to Sicily
c.) Metapontum appears to have been an opulent
werful city, whose alliance was courted by the
ns; but they contented themselves with a very
support. In 332 B.C., at the time of the expedition
ander, king of Epirus, into Italy, it was one of the
ies to espouse his cause, and enter into an alliance
m; and they appear to have in like manner lent an
upport to Pyrrhus at a later period. Down to this
herefore, Metapontum seems to have retained its
as one of the principal cities of Magna Græcia,
re is no evidence of its having suffered materially
e establishment of the Lucanians in its immediate
ourhood. Nor have we any account of the precise
at which it passed under the dominion of Rome, or
ditions under which it became subject to the great
c. But it was the Second Punic War which gave
l blow to its prosperity. After the battle of Cannæ
B.C. it was among the first cities in the south of
declare in favour of Hannibal, and after the fall of
um in 212 B.C. it not only received a Carthaginian
n, but became for some years the headquarters of
al. Hence, when the defeat of Hasdrubal at the
us (207 B.C.) compelled him to abandon this part
, and withdraw into the fastnesses of Bruttium, the
nass of the inhabitants of Metapontum abandoned
ty, and followed him in his retreat.

this time Metapontum sunk into a poor and incon-
le town; though it was still existing as such in
s of Cicero, it soon fell into complete decay, and
ias tells us that in his time nothing remained of it
heatre and the circuit of the walls. All remains of
ave since disappeared, but the site is still marked
ruins of a temple, which occupy a slight elevation
right bank of the river Bradanus, about 2 miles
s mouth. The surrounding plain, so celebrated in
times for its fertility, is now desolated by malaria,
nost uninhabited; and the remains of the city itself,
n the site of the temple and the sea, are in great part
in the alluvial deposits of the neighbouring rivers.
e excavations were carried on upon the spot by the
Luynes in 1828, and the results of his researches
ublished by him in a special work (*Métaponte*, fol.,
1833).

METASTASIO (1698–1782). Pietro Trapassi,
Italian poet who is better known by his assumed nam
Metastasio, was born in Rome, January 6, 1698.
father, Felice Trapassi, a native of Assisi, came to
and took service in what was termed the Corsican regi
of the papal forces. He subsequently married a Bolog
woman, called Francesca Galasti, and established hi
in business as a sort of grocer in the Via dei Cappe
Two sons and two daughters were the fruit of this marr

great man interested himself in the genius he had acci
ally discovered, made Pietro his protegé, and in the co
of a few weeks adopted him. Felice Trapassi was
enough to give his son the chance of a good education
introduction into the world under auspices so favour
Gravina, following a fashion for which we may find
cedents so illustrious as that of Melanchthon, Helle
the boy's name Trapassi into Metastasio; and this
remained with him for life. Gravina intended his ad
son to be a jurist like himself. He therefore made th
learn Latin and begin the study of law. At the same
he cultivated his literary gifts, and displayed the you
prodigy both at his own house and in the Roman cof
Metastasio soon found himself competing with the
celebrated improvisatori of his time in Italy. Days
in severe studies, evenings devoted to the task of impr
ing eighty stanzas at a single session, were fast ru
Pietro's health and overstraining his poetic faculty.
this juncture Gravina had to journey into Calabri
business. He took Metastasio with him, exhibited hi
the literary circles of Naples, and then placed him
the care of his kinsman Gregorio Caroprese at a little
called Scalea. In country air and the quiet of the sou
sea-shore Metastasio's health revived. It was decree
the excellent Gravina that he should never improv
line again. His great facility should be reserve
nobler efforts, when, having completed his educatio
might enter into competition with poets who had
queathed masterpieces to the world.

Metastasio responded with the docility of a pliant n
to his patron's wishes. At the age of twelve, while at
ing to classical and legal studies, he translated the *Iliad*
octave stanzas; and two years later he composed a tragc
the manner of Seneca upon a subject chosen from Tris
Italia Liberata—Gravina's favourite epic. It was
Giustino. Gravina had it printed in 1713; but the p
lifeless; and forty-two years afterwards we find Meta
writing to his publisher, Calsabigi, that he would will
suppress it. Caroprese died in 1714, leaving Gravi
heir; and in 1718 Gravina also died. Metastasio inhe
from the good old man a property, consisting of house,
furniture, and money, which amounted to 15,000 scu
about £1000. At a meeting of the Arcadian Acad
amid the tears and plaudits of that learned audienc
recited an elegy on the patron who had been to him s
a foster-father, and then settled down, not it seems wi
real sorrow for his loss, to enjoy what was no inconsid

e at that period. Metastasio was now twenty. g the last four years he had worn the costume of having taken the minor orders without which it was seless to expect advancement in Rome. His romantic y, personal beauty, charming manners, and distind talents made him fashionable. That before two were out he had spent his money and increased his tion for wit will surprise no one. He now very ly determined to quit a mode of life for which he ot born, and to apply himself seriously to the work profession. Accordingly he went to Naples, and d the office of an eminent lawyer named Castagnola. ould appear that he articled himself as clerk, for gnola, who was a stern master, averse to literary g, exercised severe control over his time and energies. slaving at the law, Metastasio did not wholly neglect luses. In 1721 he composed an epithalamium, and bly also his first musical serenade, *Endimione*, on the on of the marriage of his patroness the Princess i di Sangro to the Marchese Belmonte Pignatelli. he event which fixed his destiny was the following. 22 the birthday of the empress had to be celebrated more than ordinary honours, and the viceroy applied tastasio to compose a serenata for the occasion. He ed this invitation with mingled delight and trepidafor Castagnola looked with no favour on his clerk's al distractions. It was arranged that his authorship be kept a profound secret. Under these conditions tasio produced *Gli Orti Esperidi*. Set to music by ra, it won the most extraordinary applause. The Roman prima donna, Marianna Bulgarelli, called La nina from her birthplace, who had played the part us in this drama, was so enraptured with the beauties libretto that she spared no pains until she had dis- d its author. Asked point blank whether he had ritten the words of the successful play, Metastasio bliged to answer, Yes! La Romanina forthwith took sion of him, induced him to quit his lawyer's office, romised to secure for him fame and independence, if uld devote his talents to the musical drama. It was hat the opera, already partially developed by the ean poet, Apostolo Zeno, attained perfection. The nan had been found for maturing this form of art the genius of the age demanded, but which was still ncomplete. In La Romanina's house Metastasio e acquainted with the greatest composers of the day,— Porpora, from whom he took lessons in music; with Pergolese, Scarlatti, Vinci, Leo, Durante, Marcello, whom were destined in the future to set his plays to y. Here too he studied the art of singing, and l to appreciate the style of such men as Farinelli. ngularly pliant genius discerned the conditions which ama must obey in order to adapt itself to music in age it then had reached. Gifted himself with extraary facility in composition, and with a true poetic g, he found no difficulty in producing plays which, beautiful in themselves, judged merely as works of y art, became masterpieces as soon as their words set to music, and rendered by the singers of the st school of vocal art the world has ever seen. Read etastasio in the study, it is impossible to do him e. Our only chance of rendering him a portion of e is to approach these lyrical scenes so passionate ir emotion, so cunningly devised for musical effect— he phrases of Pergolese or Paesiello ringing in our nd to imagine how a Farinelli or a Caffariello voiced stanzas which demand for their artistic realization inked sweetness long drawn out" of melodies as the school developed them. In short, Metastasio is a whose poetry leapt to its real life in the environment of music. The conventionality of all his plots, absurdities of many of his situations, the violence he d to history in the persons of some leading characters, "damnable iteration" of the theme of love in all phases, are explained and justified by music. He can be studied with pleasure and profit. But our only cha of understanding the cosmopolitan popularity he enjo is by remembering that at least one half of the effect aimed at has been irrecoverably lost.

Metastasio resided with La Romanina and her husb in Rome. The generous woman, moved by an affection maternal half romantic, and by a true artist's admirat for so rare a talent, adopted him more passionately e than Gravina had done. She took the whole Trap family—father, mother, brother, sisters—into her own ho She fostered the poet's genius and pampered his capri Under her influence he wrote in rapid succession *Didone Abbandonata*, *Catone in Utica*, *Ezio*, *Alessan nell' Indie*, *Semiramide Riconosciuta*, *Siroe*, and *Artase* These dramas were set to music by the chief composer the day, and performed in the chief towns of Italy. Ev month added to Metastasio's renown. But meanwhile Romanina was growing older; she had ceased to sing public; and the poet felt himself more and more depend in an irksome sense upon her kindness. He gained scudi (about £60) for each opera; this pay, though g was precarious, and he longed for some fixed engagem Abandoning himself gradually to despondent whims fancies, it became clear that some change in his condi was desirable. And the opportunity for a great cha soon presented itself. In September 1729 he recei the offer of the post of court poet to the theatre at Vie with a stipend of 3000 florins. This he at once accep La Romanina unselfishly sped him on his way to gl She took the charge of his family in Rome, and he set for Austria.

In the early summer of 1730 Metastasio settled Vienna in the house of a Spanish Neapolitan, Nic Martinez, where he resided until his death. This marks a new period in his artistic activity. Between years 1730 and 1740 his finest dramas, *Adriano*, *Deme Issipile*, *Demofoonte*, *Olimpiade*, *Clemenza di Tito*, *Ac in Sciro*, *Temistocle*, and *Attilio Regolo*, were produced the imperial theatre. Some of them had to be compo for special occasions, with almost incredible rapidity— *Achille* in eighteen days, the *Ipermnestra* in nine. F composer, musical copyist, and singer did their w together in frantic haste. The impress of the pec circumstances under which they were created is still upon them, not only in negligence of style, but also in undefinable quality which marks them out as produc collaboration. But what must always surprise us is they should be as good as they are. Metastasio unders the technique of his peculiar art in its minutest det The experience gained at Naples and Rome, quickened the excitement of his new career at Vienna, enabled almost instinctively, and as it were by inspiration, to hit exact mark aimed at in the opera.

At Vienna Metastasio met with no marked s success. His plebeian birth excluded him from aristoc circles. But, to make up in some measure for this parative failure, he enjoyed the intimacy of a great l the Countess Althann, sister-in-law of his old patroness Princess Belmonte Pignatelli. She had lost her husb and had some while occupied the post of chief favourit the emperor. Metastasio's liaison with her became so that it was even believed they had been privately mar From his letters to his friend La Romanina, and to great singer Farinelli, who reigned supreme at the o of Madrid, we learn the little details of the poet's li

risome monotony, and come to comprehend his
er, at once generous and timid, selfish and amiable,
almost to excess of caution, and personally cold in
iction with the fervour of his sentimental muse.
en tenor of this dull existence was broken in the
734 by the one dark and tragic incident of his
hy. It appears that La Romanina had at last got
his absence. Little satisfied with his friendly but
at reticent communications, impatient to see him
ain, inquisitive perhaps about the terms on which
l with his new mistress, she resolved to journey to
Could not Metastasio get her an engagement at
rt theatre? The poet at this juncture revealed his
sential feebleness of character. To La Romanina he
lmost everything as a man and as an artist. But
ashamed of her and tired of her. He vowed she
not come to Vienna, and wrote dissuading her from
jected visit. The tone of his letters alarmed and
d her. It is probable that she set out from Rome,
d suddenly upon the road. Nothing can be said for
about her end, or about the part which Metastasio
ave played in hastening the catastrophe. All we
that she left him her fortune after her husband's
erest in it had expired, and that Metastasio, over-
d with grief and remorse, immediately renounced
acy. This disinterested act plunged the Bulgarelli-
asio household at Rome into confusion. La
ina's widower married again. Leopoldo Trapassi,
father and sister, were thrown upon their own
es. The poet in Vienna had to bear their angry
lations upon his ill-timed generosity, and to augment
wances he made them.

time advanced the life which Metastasio led at
, together with the climate, told upon his health
rits. From about the year 1745 onward he writes
ningly of a mysterious nervous illness, which
d him into the abyss of melancholy, interfered with
tive energy, and constantly distressed him with the
ension of a general breakdown. He wrote but
ow, though the cantatas which belong to this
and the canzonet *Ecco quel fiero istante*, which he
his friend Farinelli, rank among the most popular
productions. It was clear, as his latest and most
biographer, Vernon Lee, has phrased it, that "what
im was mental and moral ennui." In 1755 the
ss Althann died, and Metastasio was more than ever
d to the society which gathered round him in the
is house of the Martinez. He sank rapidly into
its of old age; and, though his life was prolonged
year 1782, very little can be said about it. On
h of April he died, bequeathing his whole fortune
130,000 florins to the five children of his friend
ez. He had survived all his Italian relatives.

g the long period of forty years in which Metastasio may be
said to have overlived his originality and creative powers
went on increasing. In his library he counted as many as
itions of his own works. They had been translated into
English, German, Spanish, even into Modern Greek. They
n set to music over and over again by every composer of
on, each opera receiving this honour in turn from several
ost illustrious men of Europe. They had been sung by the
tuosi in every capital, from Madrid to St Petersburg, from
to Constantinople. The critics of all nations vied in
Metastasio's credit to the skies. There was not a literary
of note which had not conferred on him the honour of
ship. Strangers of distinction passing through Vienna
point of paying their respects to the old poet at his lodgings
Kohlmarkt Gasse. Letters of congratulation, adulation,
y, respect, condolence, poured in upon him. And yet,
the whole of this long period, he was gradually outliving the
conditions upon which that fame was really founded. It
already pointed out that Metastasio cannot rank as a poet
unqualified sense of that word, but as a poet collaborating
musical composer and performer. His poetry, further-
more, was intended for a certain style of music—for the mus
omnipotent vocalists, of thaumaturgical sopran. With the cha
effected in the musical drama by Gluck and Mozart, with
development of orchestration and the rapid growth of the Ge
manner, a new type of libretto came into request. Metasta
plays fell into undeserved neglect, together with the music to w
he had linked them. Farinelli, whom he styled "twin broth
was the true exponent of his poetry; and, with the abolition o
class of singers to which Farinelli belonged, Metastasio's n
suffered eclipse. It was indeed a just symbolic instinct which
the poet dub this unique soprano his twin-brother.

The musical drama for which Metastasio composed, and in w
ing for which his genius found its proper sphere, has so wh
passed away that it is now difficult to assign his true place to
poet in Italian literary history. Compared with Shakespeare, or
with Racine, he hardly merits the title of a dramatist. His ins
tion was essentially emotional and lyrical. Instead of cre
characters, he created situations for the display of very varied
ings, for all the feelings in fact to which melody allies itself.
In doing this he showed a capable playwright's faculty. His
sonages act and react upon each other. Their characters, thoug
in harmony with history or fact, are clearly traced and cleverly
tained. Each of the dramatis personæ is an emotion incarnate
consistent, admirably fitted for musical effect and contrast.
clash and combat of passions are vividly presented, with the sm
possible expenditure of rhetoric, in the dialogues intended
recitative. The climax of emotion is cadenced in appro
stanzas, with ample but effective imagery, at the close of
important scene. The chief dramatic situations are expresse
lyrics for two or three voices, embodying the several conten
passions of the agents brought into conflict by the circumstan
the plot. The total result is not pure literature, but litera
supremely fit for musical effect. Language in Metastasio's han
exquisitely pure and limpid. Of the Italian poets, he profes
special admiration for Tasso and for Marmi. But he avoided the
ceits of the latter, and was no master over the refined richness
former's diction. His own style reveals the improvisatore's fac
Of the Latin poets he studied Ovid with the greatest pleasure
from this predilection some of his own literary qualities may b
rived. The pedantic rules of Aristotelian poetics never touch
artist who felt his real vocation to be the interpretation of n
For historical propriety, for the psychology of character, for un
plot, for probability of incident, he had a supreme disregard. I
indeed his merit to have discarded all these considerations.
poetry was the twin-sister of Italian melody, and he was rig
trusting entirely to music and action on the stage to render his
ceptions vital. What, therefore, he gained during his own life
while the musical system to which he subordinated his genius
yet living, he has since lost when, as now, he must be studie
readers who have only a faint and dim conception of that pe
art. For sweetness of versification, for limpidity of diction
delicacy of sentiment, for romantic situations exquisitely ren
in the simplest style, and for a certain delicate beauty of im
sometimes soaring to ideal sublimity, he deserves to be appre
so long as the Italian language lasts.

There are numerous editions of Metastasio's works. That by Calsabigi,
1755, 9 vols. 8vo, published under his own superintendence, was the
favourite. Another of Turin, 1757, and a third of Paris, 1780, deserve me

METEMPSYCHOSIS, the transmigration of th
as an immortal essence, into successive bodily forms
human or animal. This doctrine, famous in antiqui
one of the characteristic doctrines of Pythagoras,
to have originated in Egypt. This indeed is affir
Herodotus (ii. 123):—"The Egyptians are, moreov
first who propounded the theory that the human sou
mortal, and that when the body of any one peri
enters into some other creature that may be born r
receive it, and that, when it has gone the round
created forms on land, in water, and in air, then
more enters a human body born for it; and this
existence for the soul takes place in three thousand

Plato, in a well-known passage of the *Phædrus*,
as was his wont, the Pythagorean doctrine to his r
allegory about the soul of the philosopher. That s
says, though it may have suffered a fall in its atte
contemplate celestial things, still is not condemned
first entrance into another form, to any bestial ex
but, according to its attainments, *i.e.*, to the progress
it has made in its aspiration for celestial verities, it
in nine distinct grades, into the body of some one d
to become a philosopher, a poet, a king, a general,
&c.; or, if very inferior, it will animate a sophist
autocrat (*τύραννος*). Plato extends the cycle of ex
to ten thousand years, which is subdivided into per
a thousand years, after the lapse of which the souls u

nt, and are admitted to everlasting happiness or ned to punishment.[1] It is after the period of a d years, he adds, that the human soul comes into and from a beast again into a man, if the soul ly was human.

agoras, who was said to have travelled in Egypt,[2] this fantastic doctrine into Magna Græcia, and a prominent part of his teaching. He declared had himself been Euphorbus, the son of Panthus, time of the Trojan War, and had successively ed other human bodies, the actions of all which he bered.[3] Closely connected with his theory of metem sis was his strict precept to abstain from animal ven from eggs, from some kinds of fish, and (for nknown, probably symbolical, reason) from beans.[4] an be no doubt that the Egyptian custom of pre the mummies of cats, crocodiles, and some other es had its origin in the notion that they had been ed by souls which might some day claim these for their own. We cannot suppose that Plato or er Greeks really believed in the transmigration of hough there are many allusions to it, generally of a

nat playful character. Thus Menander, in the play *The Inspired Woman*[5] (Θεοφορουμένη), supposes od to say to an old man, Crato, "When you die, ill have a second existence; choose what creature uld like to be, dog, sheep, goat, horse, or man." ch he replies, "Make me anything rather than a or he is the only creature that prospers by injustice." rd and fantastic as such a doctrine as metem sis appears at first sight to be, it was in reality a deduction from primitive ideas about the nature of l. It is necessary to explain these ideas (which nportant bearings on other questions) in order to hat metempsychosis was almost a necessary corollary belief that the soul was the vital or animating prin that the one distinction between organic and inor was the existence in the former of a ψυχή.

difference between a dead body and a living body ather, one principal difference—was that the living breathed; and it was observed that, as soon as the left the body, not only did warmth and motion but the body began to decay. Life, therefore, was an opinion tacitly expressed by the Greek and vocabulary, *animus*, *anima* (ἄνεμος), ψυχή, πνεῦμα, s. But breath is air, and air is eternal and imperish its very nature. Therefore the "soul," or portion which gave animation to the body, did not perish at solution of the body, but it was returned to the t of which it was composed, and out of which it It followed that, from the countless millions of " emancipated from bodies in all time, and still about invisibly in space, the air must literally with souls,—a doctrine taught by Pythagoras.[6] any creature, human or bestial, that first drew the of life, might, so to say, swallow a soul, *i.e.*, take in he act of respiration the very same particles of air had animated some former body. For, although as air, and returned to its kindred element, it was ed to retain a peculiar character in intelligence (φρόνησις), remembrance of the past, and knowledge experience gained in some former existence. Any crea which first breathed might or might not inhale this or soul, just as a net thrown into the water may catch th that fish, or no fish at all. But if no "soul" was inh the creature was believed for that reason to die, and different degrees of intelligence observed in different and animals led to the notion that there must have a difference in the souls that first animated them. the belief that the soul, especially near the time of dis tion from the body, could foretell future events was b on the notion of intelligence and consciousness resul from experiences of the past.[7]

As all the science of modern times cannot say prec what life is, nor how it first came upon this earth, it is wonderful that so obvious, though wholly erroneous explanation should have presented itself to primitive when first he began to inquire into the causes of thi The extension of life, by the same term ψυχή, to plants apparently non-breathing things, which, however, had b growth, and death, was a development of a philosophic and we are not surprised to find Aristotle recognizing form of life as *vegetable*, φυτικόν.[8] The irrational confu of "soul" with sentient bodily functions, the attributio spirits (εἴδωλα) of motion, speech, or other muscular material action, though still common, while metempsych is derided or forgotten, is in reality, perhaps, a less ev able superstition.

The Romans inherited the doctrine of metempsych from Ennius, the poet of Calabria, who must have familiar with the Greek teachings which had descende his times from the cities of Magna Græcia. In his *An* or Roman history in verse, Ennius told how he had Homer in a dream, who had assured him that the soul which had animated both the poets had once belo to a peacock, a story that might seem to indicate In traditions. The *Pavo Pythagoreus* and the *Somnia Py gorea* are referred to by Persius and Horace, as well a Lucretius.[9]

Theories suggesting element-worship naturally led t notion that air and ether (upper air) were divine.[10] H every soul, as being but a portion of it, was in itself di and therefore immortal. We thus see that the doctri the immortality of the soul, whether attained by a s or a vicious course of reasoning, was an inevitable co sion for early thinkers. Pantheism taught that all universe was pervaded by a divine mind, and Virgil the opinion of some, that the intelligence of bees wa to a portion of this universal mind residing in them, a closely allied to the doctrine of metempsychosis.[11] A d thing might be polluted, but not destroyed; hence notion of purifying souls by airing them or burning a material defilement is enlarged upon by Virgil i sixth book of the *Æneid* (724 *sq.*). (F. A.

METEOR, METEORITE. The term meteor, i cordance with its etymology (μετέωρος), meant origi something high in the air. It has been applied to a variety of phenomena, most of them of brief dura which have place in the atmosphere. Disturbances i air are aerial meteors, viz., winds, tornadoes, whirlw typhoons, hurricanes, &c. The vapour of water i atmosphere creates by its forms and precipitations aqueous meteors, viz., clouds, fogs, mists, snow, rain,

in Ohio and Pennsylvania, who from their si
could look over the cloud last, saw the meteor pas
eastward over New York From many places
State itself came accounts of rattling of houses, thu
noises, and other like phenomena, which at the ti
attributed to an earthquake.

At one place in northern Indiana a farmer h
heavy thud as of an object striking the ground
house. The next morning he found on the snow a
very peculiar appearance weighing three-quarters of a
which from its character there is every reason to
came from the meteor. By putting together the
accounts of observers, the meteor is shown to have
first visible when it was near the north west corner
Indian Territory, at an elevation of between 60 a
miles above the earth. From here it went nearly
to the earth's surface, and nearly in a right line, to
over central New York. During the latter part
course its height was 30 or 40 miles. It thus tr
the upper regions of the air through 25 of longitu
5° of latitude in a period of time not easily dete
but probably about two minutes. A part of the bo
have passed on out of the atmosphere, but probab
remnants came somewhere to the ground in New
or farther east.

A somewhat similar meteor was seen in the eve
July 20, 1860, by persons in New York, Pennsy
New England, &c., which first appeared over Michi
a height of about 90 miles The light was so bril
to call thousands from their houses. It passed eas
east, and over New York State, at a height of ab
mile, broke into three parts which chased each othe
the sky. At New York city it was seen in the
while at New Haven it was in the south. At both
the apparent altitude was well observed, and its true
proved to be about 12 miles above the earth's
between the two cities. It finally disappeared far o
the Atlantic Ocean. It is doubtful whether any on
any sound of explosion that came from this mete
no part of it is known to have reached the ground
velocity was at least 10 or 12 miles per second,

Next to the stone-producing meteor is the fire
bolide, which gives generally a less brilliant light t
former, but in essential appearances is like it. The m
July 20, 1860, above described, though unusually b
was one of this class, and represents thousands of
which have been seen to break in pieces. The
leave trains of light behind them just as the stone
do; they travel with similar velocities both appare
actual, and in all respects exhibit only such differe
phenomena as would be fully explained by differe
size, cohesion, and chemical constitution of stones
them.

Next to the bolide is a smaller meteor which
as if one of the stars were to leave its place in the h
shoot across the sky, and disappear—all within the
of a second. Some meteors of this class are as b
Venus or Jupiter. Some are so small that though y
directly at the meteor, you doubt whether you see

n the telescope still smaller ones are seen that are
e to the naked eye. Meteors comparable in bright
the planets and the fixed stars are usually called
g stars.

e various kinds of meteors differ from all other
ns phenomena so as to stand in a group entirely
Though they have been sometimes regarded as
ble among themselves into three or four different
and for purposes of description may still be so
, yet they all seem to have a like astronomical
er, and the differences are only those of bigness,
al constitution, velocity, &c. There appears to be
r line of distinction between the stone producing and
onating meteors, nor between those heard to explode
ose seen to break in pieces, nor between these and
mple fireballs, nor between the fireball and the
shooting-star.

ades of Meteors. The first important fact about
eteors is the region in which they become visible to
hundreds of instances observations have been
pon the luminous path of a meteor at two or more
s many miles apart. When such stations and the
e properly situated relatively to each other, observa
arefully made will show a parallax by which the

d as between 40 and 80 miles above the earth'
. Some first appear above 80 miles, and some
l below 40 miles. But an altitude greater than
les, or one below 25, except in the case of a stone
ing meteor, must be regarded as very doubtful.
he meteor paths are far above the usual meteoro
phenomena, which (except aurora and twilight)
ot one tenth of the height of the meteors. But
ference to all other astronomical phenomena they
y close to us. The comets, for example, are well
millionfold, and even the moon is a thousandfold,
istant from us.

ities of Meteors. When the length of a luminous
known, and the time of describing it has been
d, it is easy to compute the velocity in miles.
mately the large meteors, describing long paths,
t rare intervals, and unexpectedly, and it is a happy
t when one is observed by a person accustomed to
e correctly short intervals of time. On the other
the total time of visibility of the shooting stars,
come so frequently that they may be watched for,
lly less than a second. It is not easy to estimate
ly such an interval, where the beginning and ending
marked by something like a sharp click. Hence
nates and computations of velocities of meteors are to
ived with due regard to their uncertainty. We may
y in general that the velocities computed from good
ations are rarely if ever under 8 or 10 miles a second,
40 or 50 miles, and that some have far greater
es than others. The average velocity seems to be
30 miles.

t makes the Luminous Meteor. The cause of a
is now universally admitted to be something that
the earth's atmosphere from without, with a
y relative to the earth that is comparable with the
velocity in its orbit, which is 19 miles per second.
resistance it meets in penetrating the air the light
her phenomena of the luminous train are produced.
favourable circumstances, portions of these bodies
he earth's surface as meteorites.

oroids.—A body which is travelling in space, and
on coming into the air would under favourable
circumstances become a meteor, may be called a
oid.

The meteoroids are all solid bodies. It would
be possible for a small quantity of gas out in
retain such a density as would enable it on comi
the air to go 10 or 100 miles through even the ra
atmosphere, and give us the clear line which a
star describes. Even if a liquid or gaseous mass ca
as such in space, it would be instantly scattered on
the air, and would appear very unlike a shooting
bolide.

Numbers of Meteors. Of the larger meteor the
the mean six or eight per annum which in the last fif
have furnished stones for our collections. A much
number have doubtless sent down stones which hav
been found. Thus Daubree estimates for the whol
an annual number of six or seven hundred stone fal

But of the small meteor or shooting star the
very much larger. Any person who should o
moonless night watch carefully a portion of the
would, in the mean, see at least as many as eight
shooting stars per hour. A clear sighted and pr
observer will detect somewhat more than thi
Dr Schmidt of Athens, from observations made
seventeen years, obtained fourteen as the mean hour
ber on a clear moonless night for one observer dur
hour from midnight to 1 A.M. A large group of ob
as has been shown by trial, would see at least six
many as a single person. By a proper consideration
distribution of meteor paths over the sky, and
altitude in miles, so as to allow for mist near the
it appears that the number over the whole globe
more than ten thousand times as many as can be
one place. This implies that there come into the at
than twenty million bodies daily, each of which
very favourable conditions of absence of sunlight,
light, clouds, and mist, would furnish a luminou
visible to the naked eye. Shooting stars may be
naked eye are often seen in the telescope. The n
of meteors, if these are included, would be rec
least twentyfold.

How densely Space is filled with Meteoroids. By as
that the absolute velocity of the meteor in space
to that of comets moving in parabolic orbits (we hav
reason to believe that this is nearly their true velo
may prove from the above numbers that the average
of meteoroids in the part that the earth traverses is
volume equal to that of the earth, about thirty th
In other words, there is on the average to every po
space equal to a cube whose edge is about 210 m
meteoroid large enough to make a shooting star
enough to be visible to the naked eye. Such me
would, upon an equable distribution, be each a
number 250 miles from its nearest neighbours. All the
bers rest upon Dr Schmidt's horary number fourte
for a less practised observer and a less clear sky they
be correspondingly changed. How much they wo
to be altered to represent other parts of space tha
near the earth's orbit is a subject of interest rath
of observation.

Motion in space.—The meteoroids, whatever
size, must by the law of gravitation have motion
the sun in the same way as the planets and comet
is, in conic sections of which the sun is always at on
The apparent motions of the meteors across the sk
that these motions of the meteoroids relative to
cannot as a rule be in or near the plane of the
For if they were there, since the motion of the earth
in the ecliptic, the motion of the meteoroids relativ
earth would be in the same plane. This would

ll the meteor paths as seen on the sky would if pro- backward cross the ecliptic above the horizon. In here is no tendency of this kind. Hence the meteor- o not move in orbits that are near the ecliptic as the s do, but like the comets they may and usually do orbits of considerable inclinations.

mbers through the Night.—There are more meteors in the morning hours than in the evening. If the rs had no motion of their own in space, the earth l by its motion receive the meteors only on the hemi- e that was in front. There would be no meteors seen other hemisphere. On the other hand, if the meteors ach large velocities of their own as that the earth's ty might be neglected in comparison, and if the ions of the meteors' motions were towards all points riminately, then as many would be seen in one part night as another. In fact there are about three as many seen in the morning hours as in the evening. s of chance from evening to morning gives a means ving that the mean velocity of meteors is so great hey must in general be moving in long orbits about n. In this respect also the meteoroids resemble and are unlike planets, in their motions. Of the turning meteors more are seen in the day than in ght, and more in the earlier hours of the night than later. This is probably due to the fact that more are in a position to see the zone fall at the period ater abundance.

Showers.—While the average number of shooting or a single observer at midnight may be regarded as ly constant, there have been special epochs when more have been seen. In certain instances the sky en filled with the luminous trains, just as it is filled scending snowflakes in a snowstorm, making a ible shower of fire. One of the best observed, though not the most brilliant, of these showers occurred evening of the 27th of November 1872. Some of ers of that shower, counting singly, saw at the s eight or ten thousand shooting stars in the course hour. The distances of the meteoroids in the of the warm which the earth then passed through, rom its nearest neighbours, would be 30 or 40 miles. following quotations show the impression made by owers in time past.

On several years after 1833, and before an 1866 68, there were unusual numbers of those mete on the mornings of November 13, 14, and 15, thou haps they would have been unnoticed had there n special watching for them. It will be seen that a showers are at intervals of a third of a century, th are at a fixed day of the year, and that the day has steadily and uniformly along the calendar at the about a month in a thousand years. The change of days in the 17th century is due to the change from new style.

The only explanation of this periodical display now seriously urged, and the one which is uni accepted by astronomers, is that there is a long thin of meteoroids, each of which is travelling about the a conic section. These conic sections are all parallel, and have nearly the same major axis, ex out about as far as to the orbit of Uranus, and each ing the common period of thirty three and a years. The length of the stream is such that th advanced members are six or eight years ahead hindermost, and they all cross the earth's orbit velocity of about 26 miles a second. Since the plunges through the group nearly in the opposite di the velocity with which they enter the air is 44 second. One of the facts which have greatly aide arriving at this explanation is that these meteors the years and through all hours of the night cross as we look at them in lines which diverge from near the centre of the sickle in the constellation Leo the paths in the air are parallel. This implies tha velocities relative to the sun are all parallel and e each other. The radiation from Leo has given to th name *Leonids*.

Orbit of the Leonids.—This orbit, common to Leonid meteors, is inclined to the ecliptic at an angle (or rather 163°, since the motion is retrograde), has axis of 10·34, a periodic time of 33·27 years, and helion distance a little less than unity.

The above orbit, and that alone, explains the appearances of the November meteors, the annual thirty three year periods, the radiation from Leo, change of day of the month in the course of the ce This it does so completely that the result has nev questioned by astronomers. Shortly after the pub by Professor Adams in 1867 of the last link in th of the proof of this orbit, there was also publish definitive orbit of the comet 1866 I. That the com running almost exactly in the orbit of the meteors once recognized. In fact the comet is itself, in a meteoroid, and the principal member, so far as we of the group. Leonids had been seen in 1863, tw and two months in advance of the comet, while t 1866 were ten months behind it. Those of later y few Leonids were seen even in 1870) were extende the line of the comet's path behind it. The leaders long file of meteoroids had passed up beyond the Jupiter long before those which brought up the r crossed that planet's orbit going down toward th The thickness of the stream is less than the ten-thou part of its length. In the densest part that w recently passed through - namely, that traversed in the density of the stream may be expressed by sayi each meteoroid must in the mean have been 10 miles from its nearest neighbours.

What makes this Comet and these Meteors desc same Orbit about the Sun?—Its path might hav inclined to the ecliptic at any angle instead of 163 with this inclination, its plane might have cut the orbit at any other place than where the earth is on t

the year 286 [of the Hegira] there happened in Egypt an ake on Wednesday the 7th of Dhu l-Ka'dah, lasting from the of the night until morning, and so-called flaming stars one giant another violently while being borne eastward uthward and southward, and no one could bear to w it the heaven on account of this phenomenon."

the year 399 [of the Hegira], on the night of Saturday, on th of Muharram, stars shot hither and thither in the s eastward and westward, and flew against one another like r of swarms of locusts, to the right and left, people were n consternation, and cried to God the Most High with d clamour.

vember. Or, happening to have these two elements
non, it might have passed the earth's orbit nearer
n or farther away from it than the earth is. Or,
g these three things in common, it might, by a slight
nce in velocity, have had a periodic time much more
ch less than thirty-three years. Or, with all these
mon, it might have crossed the earth's orbit at a far
nt angle than the meteors. These several independ-
ements for the comet and the meteors are substan
identical, and this identity proves almost beyond
that between the two either there is now an actual
there has been in the past a causal connexion.
there is now any physical connexion is thoroughly
ved by the immense magnitude of the stream, and
e isolation and distances from each other of the
dual components. It seems difficult to find any cause
should bring into such a strangely shaped group
that had originally orbits distributed at random.
we are apparently forced to conclude that these
roids have something common in their past history.
t they seem to have been once parts of a single body,
hese common elements are essentially those of the
mass. By some process not yet entirely explained
ave become separated from the comet, thrown out of
ntrol of its attractive power, and so left to travel
ne in its own orbit. If the cause of separation was
o violent, each new orbit would necessarily be but
y different from that of the comet. Very small
ions in velocity, and hence in periodic time, would
course of ages scatter the several individuals along
bit even to the length of many hundreds of millions
es.

Meteor Group is not the Comet's Tail. These
roids must be carefully distinguished from the
's tails. The former follow or precede the comet
y in the comet's path; the particles that compose
tter are driven off by the sun's repulsion directly
from the comet's path. The meteoroids and the
have orbits with nearly common elements; the
of the particles of the tail have elements that are
each other, and unlike those of the comet. The
roids are undoubtedly solid masses; the tails are
nulent or gaseous.

in Comets of 1366. The comet 1866 I. is probably
e only one that has been connected with the November
rs. In 1366, a few days after the earth went through
neteor stream, a comet appeared in the northern
ns, and, passing directly in the line of the stream so
to the earth as to describe an arc of 90° in a single
disappeared in the constellation Aquarius. Immedi-
upon its disappearance a second comet was seen in
orth, which followed nearly in the same path. The
se accounts are not sufficiently exact to furnish
endent orbits for them, but both comets were
ubtedly members of the Leonid stream. The comet
I. may be identical with one of them.

Andromeds and Biela's Comet. Mention has been made of the
ower of November 27, 1872. The periodical comet known
a's, which makes three revolutions in twenty years, passes
near the earth's orbit at a longitude corresponding to
mber 27, but by reason of its direct motion the node has
nsiderable motion in longitude as the result of perturbations.
s having the same orbits as Biela's comet would have a
in the constellation Andromeda, that is, would cross the
lines diverging from a point in that constellation. They
however, be at dates after or even before November 27.
sual numbers of meteors were seen December 7, 1798, by
es. A like abundance was seen December 7, 1838; and, as
ad been expected, and radiation was now looked for, they
ound to diverge from a point in Andromeda. Hence they
een called Andromeds. Since 1852 Biela's comet itself has
entirely lost. The star shower of November 27, 1872,
usly referred to, had a adiant in Andromeda, and in every
way appeared as though its meteors had once been parts of
comet. A sprinkle three days earlier, on the night of Nov
24, had the same radiant, and came from a less dense or
parallel stream. A small comet was seen in the southern
Pogson in the direction opposite to the radiant shortly aft
shower. Biela's comet had been found in 1845 46 to be
parts, which at its next return to perihelion in 1852 had sep
to eight times their former distance. But the meteor sho
1872 could hardly have been separated from the comet so re
and the Pogson comet II of the same origin must also have
parent mass at an earlier date than 1815. No ordinary pe
tions would in a short period have so changed the orbits
parts of the small stream traversed by the earth, December 1
December 1798, were far from the comet, and these fragment
have been thrown off much earlier.

The Perseids and the Comet 1862 III.—There is a third
when meteors appear in unusual numbers, viz., the 9th to
August. This "sprinkle," as it may be called, has been see
stantly at the time named for nearly fifty years, and the
on record accounts of similar appearances in the earlier years
its annual character had been discovered. Some observer
thought that there were evidences of a variation having
period, but the proof seems as yet unsatisfactory, and the
may be regarded as tolerably constant from year to year. On
10th of August we may confidently expect a display of meteo
shall be at least four or five times as numerous as those of o
nights. The radiant is in the constellation Perseus, and her
name Perseids.

The comet 1862 III., which has a period of more than a hu
years, passes close to the earth's orbit, nearly cutting it at th
of this shower, and has a velocity and direction corresponding
this radiant. Hence a connexion of the Perseid meteors wi
comet is presumed like that which the Leonids and Andr
have with the comet 1866 I and Biela. The meteors are
buted along this orbit more regularly than along either of th
two, and at the same time the breadth of this group is a hu
times greater than that of the Leonids. We must for the
regard it rather as a meteor ring, the meteoroids being sc
along the entire conic section which the comet describes. Th
has an inclination of 113° with the ecliptic.

Meteors of April 20–21. *Lyrids.* About the 20th of Apr
have been several quite brilliant star showers, the earli
record having been in the year 687 B.C. On that day meteo
been observed which radiated from Lyra, and to these the
Lyrids has been given. The comet 1861 I passes near the
orbit in that longitude, and any meteors having such a con
with it as is proved for the Leonids with comet 1866 I wou
radiate from Lyra.

Again, at several other periods of the year, meteors hav
seen in unusual numbers which seem to be connected with
comets.

Meteor Radiants. We have thus definite proof th
earth at certain epochs plunges through meteor st
and that these streams travel along the same track
tain comets. The question is at once asked. Do n
sporadic meteors, those which are seen on any a
nights of the year, belong to similar streams? An im
amount of labour has been spent in observing the pa
meteors, and classifying them, so as to detect and pro
existence of radiant points. As many as a thousan
radiants have been suggested by the different investi
Some of these are duplicates, some will prove to b
dental coincidences; but a goodly number may reas
be expected to endure the test of future observ
Such will show the existence of meteor streams, an
haps will be connected with comets that are now k
or that may hereafter be discovered.

The radiants have been spoken of as if they were
in the heavens. This is so nearly true as to justify
conclusions that have been deduced above. But in
radiant, even in the star showers in which it i
sharply defined, must be regarded as a small area.
apparent meteor paths when produced backward
exactly meet in a point. If they be treated as proc
from a small area, it does not appear that this is
narrow one. Hence it may be shown that the pa
the meteors in the air are not exactly parallel eithe
line or to a plane. This can hardly be due to a w
parallelism of the paths before the meteoroids me
earth, but is rather due to their glancing as they str

These facts add not a little to the difficulties to be
ome by the energetic observers and investigators who
rying to deduce order out of an apparent chaos.

eteorites. The fragments which fall immediately after
disappearance of large meteors have been carefully
ted and preserved in mineralogical museums, and have
studied with special interest. The largest collections
urope are in Vienna, Paris, London, and Berlin, some
ese representing over three hundred localities. In the
ed States there are large collections at New Haven,
ord, and Louisville.

several respects these fragments differ at first sight
terrestrial rock.

ey are when found almost always covered in part or
ely with a very thin black crust, generally less than
t an inch in thickness. This crust may have a bright
ous surface, or it may be of a lusterless black. It has
ently been melted, yet so rapidly as not to change in
least the parts of the stone immediately adjacent.
ks showing the flow of the melted matter are often

on the surface. Upon some surfaces are what appear
deposits of the melted matter that has flowed off from
ther. Some surfaces are only browned, showing an
ently recent fracture, and some cracks are found in
s which are not yet completely broken in two.

e surfaces very often have small cup-like cavities,
times several inches in diameter, sometimes like deep
nts in a plastic mass made by the ends of the fingers,
sometimes still smaller. These "cupules" have not
various sizes in different stones, but even in the same
differ considerably from one surface to another. They
r in meteorites that are almost exclusively iron, as
as in those mainly destitute of that metal, and they
be regarded as a characteristic of meteorites.

e meteorites have usually metallic iron as one of their
onent parts. Native iron is very rare indeed among
trial minerals, and its presence in the meteorites is
tore characteristic. Sometimes the iron forms the
ipal part of the body, giving it the appearance of a
of that metal. Sometimes it forms only a connected
work which is filled in with mineral matter. Some
particles of iron are scattered through a stony mass;
few meteorites are said to be destitute of metallic
altogether. The metallic iron is always accompanied
nickel.

e stony meteors when broken or cut through have
ly a greyish interior, and often exhibit a peculiar
lar structure. From the small rounded grains that
t this appearance, the name chondrite (from *χόνδρος*,
) has been applied to this kind of meteorite. Some-
the irregular fragments are compacted into a kind of
ia.

e pieces as we find them are always apparent frag-
of some larger mass, and there is no structural
rance which would indicate that the mass might not
fragment of a still larger one. In some of the falls
ents picked up at a distance of miles from each other
gether in this way browned surfaces, showing that
were true fragments recently separated. In some
surfaces of the stone are partially polished. In some
s section of the stone exhibits thin black lines as
gh the melted matter of the surface had been forced
the crevices of the partially broken stone.

e stones when seen to fall, if at once picked up, are
ly too warm to be taken in the hand. But cases are
ord in which the stones were excessively cold. They
times, on striking the ground, penetrate into it from
feet. In extreme cases large ones have struck much
er into soft earth. Sometimes they are broken to
s by the impact with the hard earth.

The stones are usually not very large. Althou
light of the meteor is such as sometimes to be seen
region 1000 miles in diameter, and the detonatio
phenomena suggestive of an earthquake over many e
yet a stone exceeding 100 lb is quite exceptional in
lections. The total weight secured at any fall has n
ever amounted to a thousand pounds. The average
of nine hundred and fifty perfect specimens of the
fall in the Paris museum is 67 grammes, or less t
oz. One of the Hessle meteorites in the Stockholm m
weighs less than 1 grain. Many of the Emmet count
orites (May 10, 1879) are not much larger, thou
largest specimen of that fall weighs nearly 500 lb.

Meteors traversing the Atmosphere.—We can no
very good idea of the history of that part of a met
life between its entrance into the air and its arrival
earth. It is entirely invisible until it has reached that
at which the density of the air is enough to crea
siderable resistance. Up to that time it moves
exclusively in obedience to the sun's attraction,
earth's attraction may be neglected, especially duri
passage through the air. Since the velocity is a h
times that of sound, the elasticity of the air is impo
remove it from in front of the meteorite, or to pro
high degree of condensation. Perhaps the air is fi
immediately in front of the stone. Heat is develope
enormously, and the stone being pressed closely agai
hot air is melted, with an intense light. The conde
charged with the melted matter is pushed aside, a
behind nearly in the wake of the meteor to form th
The brightness of the train rapidly diminishes beh
meteor, so that the light of the meteor and the train
fied by irradiation, make the whole appear to a dist
of the shape of a pear or candle-flame. The stone
poor conductor of heat, and itself rigid, is not heated
interior either by condensation or conduction, an
reach the ground with its surface only heated, wh
interior is as cold as it had been out in space.

If the stone is a small one it will soon be used
this intense fire. Until its front surface is rounded
flame, the irregular resistances may cause such a s
glance. But if the stone is larger it will lose veloc
rapidly. As it comes down into the region where
is more dense, it will in spite of loss of velocity meet
resistance. The air pressed hard against it burns
equally, forming cupules over its surface. The
of the air cracks the stone,—perhaps scaling off sma
ments, perhaps breaking it into pieces of more
size. In the latter case the condensed air in front
meteor being suddenly relieved will expand, givi
terrific explosion which accompanies such breaking u

different colours are seen in the different parts of
n.

ntude.- Some computations have been made of the
the shooting star meteoroids from the mechanical
ent of the light developed by their disintegration.
e energy of the meteor is changed into light, then
omputations would be conclusive But a part is
n disintegrating and burning the stone, a part
ng the air, and a part in giving direct motion to
s of air. A computation based on the light developed
nly a lower limit to the size.
ems probable that the larger meteors might be safely
d as weighing on entering the air only a few
ds or at most a few thousands of pounds. The
t visible shooting stars may be equal in size to
grains of sand, and still be large enough to furnish
light exhibited by them. The largest shooting
rnish matter enough to fill with thin trains
niles of space, but this need not require a very
ass.

e Irons.- There have been found at various times on the
of the earth masses of metallic iron combined with nickel.
ve been so like the irons which have been known to fall,
their structure and in composition, that they have been
hesitation classed among the meteoric irons. A mass of
acter weighing 1635 lb, found in Texas, is in the Yale
Museum. The Chaco (Mexico) iron in the Paris museum
the same size. A ring-shaped mass somewhat smaller,
uzon, is in the United States National Museum in
gton. A still larger mass is in the British Museum, and
ther large masses are in public collections or private
n.

annstatten Figures If in any of the meteoric irons, whether
fall or found on the earth, a section is cut and polished and
hed with acids, a series of peculiar lines are developed
re known as Widmannstatten figures The lines of iron
ed by the acid consist of an irregular grouping of parallel
often lying along the faces of a regular octahedron. The
n of these figures and the combination of iron with nickel
en usually considered conclusive evidence of the meteoric
f any iron mass.

l Iron of Ovifak.- In 1870 Baron Nordenskiold in his voyage
nland, found on the shore of the island of Disco fifteen iron
the largest of which weighed 20 tons, all in an area of half
In the basaltic rocks not far distant other iron masses
nd embedded in the basalt. The presence of nickel with
, and the development of lines like the Widmannstatten
were at once accepted as proof of their meteoric origin, in
the combination with basalt. A more complete examination,
s, however, established the terrestrial origin of these irons
en reasons to hope for new discoveries of relations existing
the earth and the meteors. The additional discovery
l particles of metallic iron in certain other igneous rocks
that the union of the Ovifak irons with basalt is not excep-

ical Constitution of the Meteorites. - No new element has
nd in the meteorites Three elements most widely distri-
nd most important among the meteorites- iron, silicon, and
—are also most abundant in our earth Daubrée gives the
ng lists of elements, arranged somewhat in the degree of
nportance, in meteorites (Maskelyne adds lithium and
ay):—

Iron.	Titanium.	Arsenic
Magnesium.	Tin.	Phosphorus
Silicon.	Copper.	Nitrogen.
Oxygen.	Aluminium.	Sulphur
Nickel	Potassium	Chlorine
Cobalt.	Sodium.	Carbon
Chromium.	Calcium	Hydrogen
Manganese.		

Minerals in Meteorites. Among the minerals in the meteo
there are several which occur in the rocks on the earth A
these are cited by Daubrée peridote, pyroxene, enstatite, tr
felspar, chromite, magnetic pyrites iron oxide, graphite
probably water Several minerals, however, are found whic
far as now known, are peculiar to the meteorites :- metallic
iron, phosphide of iron and nickel schreibersite), sesquisulph
chromium and iron (daubréelite), sulphide of calcium (oldha
and chloride of iron (lawrencite).

Meteorites of different falls are in general unlike ; but the
many instances in which the stones of two falls are so sim
constituted that it is not easy to distinguish them.

In four falls (Alais, Cold Bokkeveld, Kaba, and Orgeui
tones contain little or no iron. In these carbon appears
graphite but in union with hydrogen and oxygen, and also
soluble and even deliquescent saline matters. The combin
are such as to suggest the existence of hydrous and organic re
But after careful search nothing of this kind has been detect
them In general the meteorites show no resemblance in
mechanical or mineralogical structure to the granitic and s
rock- on the earth One condition was certainly necessary in
formation, viz., the absence of free oxygen and of enough wa
oxidize the iron and other elements Perhaps it is to this fac
are due the resemblances between the minerals and those
deep-seated rocks of the earth in the formation of which
oxygen and water were also not present

Gases in Meteorites. The meteoric irons and stone
reduced to fine particles and placed in the vacuum of a Spreng
pump give off small quantities of gases which may be reasonabl
sumed to have been occluded by the irons at some time in their
history Professor Graham found hydrogen in meteoric
Professor Wright has shown that a mode of heat drives off
the stony meteorites carbonic acid and carbonic oxide w
small amount of hydrogen. As the heat increases the proport
hydrogen (and even some nitrogen) increases still at a full red he
hydrogen given off is by far the largest portion. From the irons
gases are given off, but the carbon compounds are not so
component as hydrogen The spectra of the tails of com
not strikingly like those of any of the gases But it is impo
to reproduce in the laboratory the conditions under whic
matter of comet's tails is giving off its heat We cannot th
say that these gases may not be the important parts of the c
coma and tails

Meteoroid as Part of a Comet A suggestion that the meteor
meteoroid once formed an integral part of a comet, not
information is given us of the nature of the mysterious
There is room also for speculation.

First, the comet may be a single large body which come
the cold of space into the heat of the sun and there ha
ments broken off, just as a stone is broken off in a hot fur
nucleus of some of the comets must be very small because in
in the telescope and an impulse that would drive a stone
earth only a few inches would send it perceptibly away fro
a comet. The exposure of new surfaces to the heat of the sun
give occasion for the development of gas to form the comet's

Or, secondly, the comet may be a tolerably compact aggrega
small bodies not in contact, each one being of the siz
meteoroid, and kept near to the rest, not by cohesion, but b
combined attraction. The total mass being small, some m
of the group near the comet's perihelion passage can be by th
perturbing action thrown out into orbits quite independent
comet itself, and yet such as relative to the sun shall resemb
of the main group Perturbations resembling tidal waves m
preparing other members to be cast off at the next pe
passage of the comet.

In either case, if we suppose, as seems probable, that the
came from outside the solar system, and that a disturbanc
large planet changed the original hyperbolic orbit into an
the comet must have passed that planet as a very compact g
not in a single mass, else the disturbance that changed th
would have scattered the group beyond the power of a future
union of the common origin of the fragment

Meteoroids as Fuel of the Sun.—The idea has been h
distinguished physicists that the meteoroids in falling in
sun furnish by their concussion a supply for the heat wh
sun is constantly sending off into space, - that they are in f
fuel of the sun Such a view, however, receives but little s
from facts which we know about meteor The meteoroids

METEORA, a remarkable group of rock-built monas... ...The... ...aly, in the northern side of the valley of the ...not quite 20 miles north-east of Trikkala, and in ...mediate vicinity of the village of Kalabaka, Stagus, ...(the ancient Ægminium). From the Cambunian ...vast masses of rock are thrust southward into ...a, surmounted by a number of huge isolated columns from 85 to 300 feet high, "some like gigantic tusks, some like sugar-loaves, and some like vast stalagmites," but all consisting of iron-grey or reddish-brown conglomerate of gneiss, mica-slate, syenite, and greenstone. On the summit of these rocky pinnacles—accessible only by aid of rope and basket let down from the top, or in some cases by a series of almost perpendicular ladders climbing the cliff to the mouth of a tunnel—stand the monasteries of Meteora (*τὰ Μετέωρα*). At one time they were twenty-four in number; but Holland (1812) and Hughes (1814) found them reduced to ten; at Curzon's visit (1834) there were only seven; and in 1853 not more than four of these were inhabited by more than two or three monks. Meteora *par excellence* is the largest and perhaps the most ancient. The present building was erected, according to Leake's reading of the local inscription, in 1388 (Bjornstahl, the Swedish traveller, had given 1371), and the church is one of the largest and handsomest in Greece. St Barlaam's and St. Stephen's (the latter founded by the emperor John Cantacuzene) are next in importance. The decorations of the churches contain a large amount of material for the history of Byzantine art, not much inferior in value to the similar treasures at Athos.

Unless the identification with the Ithome of Homer be a sound one, there is no direct mention of the rocks of Meteora in ancient literature, and Professor Kriegk suggests that this may simply be due to the fact that they had not then taken on their present remarkable form. Ægnium, however, is described by Livy as a strong place, and is frequently mentioned during the Roman wars; and Stagus appears from time to time in Byzantine writers.

See Holland, *Travels in the Ionian Isles, &c.*, 1815; Hughes, *Travels in Greece and Albania*, 1830; Curzon, *Visit to Monasteries in the Levant*, 1849; Leake, *Northern Greece*; Professor Kriegk in *Zeitschr. f. allg. Erdk.*, Berlin, 1858; Tozer, *Researches in the Highlands of Turkey* 1869.

METEOROLOGY

METEOROLOGY, in its original and etymological sense, included within its scope all appearances of ...astronomical as well as atmospherical, but the term ...restricted to the description and explanation of the ...ena of the atmosphere which may be conveniently ...under weather and climate. These phenomena ...the action of the forces on which the variations ...ure, temperature, humidity, and electricity of the ...here depend, but in an especial sense to the aerial ...nts which necessarily result from these variations. ...e more exact development of meteorology, the ...investigation of climate long preceded that of ... Humboldt's work on *Isothermal Lines*, published ..., must be regarded as the first great contribution ...orological science. The importance of this inquiry ...distribution of terrestrial temperature it is ...possible to overestimate, for, though the isothermals ...necessarily to a considerable extent hypothetical, ...cannot be a doubt that they presented a first sketch ...principal climates of the globe. Dove continued ...tended the investigation, and in his great work *On ...tribution of Heat on the Surface of the Globe*, pub... ...in 1852, gave charts showing the mean temperature ...world for each month and for the year, together with ...of abnormal temperature. To this, more than to ...er work, belongs the merit of having popularized ...nce of meteorology in the best sense, by enlisting in ...ce troops of observers in all parts of the civilized ...

...868 another series of important charts were pub... ...representing by isobaric lines the distribution of the ...the earth's atmosphere, and by arrows the prevail... ...ds over the globe for the months and the year. ...charts the movements of the atmosphere and the immediate causes of these movements were for the first time approximately stated, and some knowledge was thereby attained of some of the more difficult problems of meteorology. It was shown that the prevailing winds are the simple result of the relative distribution of the mass of the earth's atmosphere, in other words, of the relative distribution of its pressure, the direction and force of the prevailing winds being simply the flow of the air from a region of higher towards a region of lower pressure, or from where there is a surplus to where there is a deficiency of air. It is on this broad and vital principle that meteorology rests, which is found to be of universal application throughout the science, in explanation, not only of prevailing winds, but of all winds, and of weather and weather changes generally. One of the more important uses of the principle is in its furnishing the key to the climates of the different regions of the earth; for climate is practically determined by the temperature and moisture of the air, and these in their turn are dependent on the prevailing winds, which are charged with the temperature and moisture of the regions they have traversed. The isobaric charts show further that the distribution of the mass of the earth's atmosphere depends on the geographical distribution of land and water in their relations to the sun's heat and to radiation towards the regions of space in different seasons.

In 1882 Loomis published a map showing the mean rainfall of the globe. This map and others that have been constructed for separate countries show conclusively that the rainfall of any region is determined by the prevailing winds considered in relation to regions from which they have come, and the physical configuration and temperature of the part of the earth's surface over which they blow. The maximum rainfall is precipitated by winds which,

traversed a large breadth of ocean, come up against
w over a mountainous ridge lying across their path,
e amount deposited is still further increased if the
pass at the same time through regions the temper-
f which constantly becomes colder. On the other
he rainfall is unusually small, or *nil*, when the pre
winds have not previously traversed some extent
n, but have crossed a mountain ridge and advance
same time into lower latitudes, or regions the
ature of which is markedly higher.

le the observational data for the determination of
ographical distribution of the prime elements of
, viz., the pressure, temperature, moisture, and
ents of the atmosphere and the rainfall were being
but surely collected, the great importance of the
of weather came gradually to be recognized.
onal impetus was given to this branch of study from
mate bearings on the eminently practical question
n warnings. Synchronous weather maps, showing
eather over a considerable portion of the earth's
, were constructed, and some advance was made in
the progress of storms from day to day. Unques-
y one of the first problems of meteorology is to
in the course storms usually follow and the causes
ch that course is determined, so as to deduce from
eteorological phenomena observed, not only the
approach of a storm, but also the particular course
orm will take. The method of practically conduct-
s large inquiry in the most effective manner was
by the genius of Leverrier, and began to be carried
1858 by the daily publication of the *Bulletin Inter-*
l, to which a weather map was added in September
This map showed graphically for the morning
day of publication the atmospheric pressure, and
ection and force of the wind, together with tables
perature, rainfall, cloud, and sea disturbance from a
umber of places in all parts of Europe. From such
r maps forecasts of storms are framed and suitable
gs issued; but above all a body of information in a
ndy form is being collected, the careful study and
ion of which is slowly but gradually leading to the
more exact and satisfactory forecasts of weather,
a juster knowledge of these great atmospheric move
which form the groundwork of the science.

most cursory glance is sufficient to show that the
anging physical phenomena with which it is the
s of meteorology to deal are all referable to the
of the sun, it being evident that if the sun were
out from the sky a cold lifeless uniformity would
take possession of the whole surface of the globe.
ological phenomena naturally group themselves into
eat classes, -those dependent on the revolution of
th on its axis, and those dependent on its revolution
the sun taken in connexion with the inclination of
to the plane of its orbit. The science thus divides
nto two great divisions, the first comprising diurnal
nena and the second annual phenome

Diurnal March of Phenomena.

perature.—Of the daily changes which take place
tmosphere, the first place must be assigned to those
rekate to temperature, seeing that on these all other
s are either directly or indirectly dependent. Obser-
of the temperature of the air are therefore of the
nportance in meteorology. A perfectly accurate
ation of the temperature of the air is unquestionably
the most difficult to make of all physical observations,
ficulty being to eliminate the effects of radiation of
ding objects. The nearest approach yet made to
ation of this important problem of physical inquiry
was made by Dr Joule in a communication
Philosophical Society of Manchester (November '76,
Proc., vol. vii. p. 35). But the manipulative ski
time demanded by the method there detailed render i
unsuitable for general adoption anywhere in collecti
observational data required in the determination
important element of climate. It is therefore neces
fall on some method which, while it gives results th
only be regarded as approximate, secures the es
element of uniformity among the observations.

Fig. 1 represents Stevenson's louvre boarded box for t
nometers, which is now very widely used for temperature
tions. The box is made of wood, and louvred all round
protect the thermometers inside from radiation, and at the sa
seems as free a circulation of air as is consistent with a sati
protection from radiation. The box is painted white, both
and outside, and screwed to four stout wooden posts, also
white, firmly fixed in the ground. The posts are of such
that when the thermometers are hung in position the bulb
minimum thermometer and hygrometer are exactly at t
height of 4 feet above the ground, the maximum thermomet

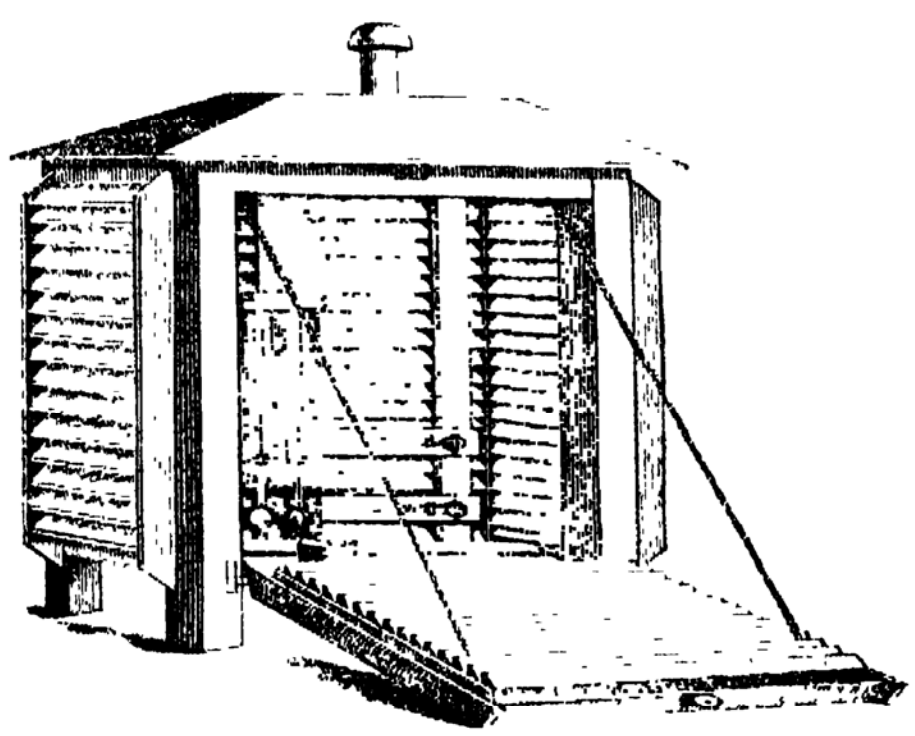

Fig. 1. The ter Bo

hung immediately above the min mum therm meter. Th
mometer box is placed over a plot l grass, and in a free op
to which the s rays have free access during as much of
as surrounding nditions admit. It will observed
thermometers s suspended on cross-laths in the centr f
and face the door, which ld always open to the n h
not possible to overestimate the importance of seeing that un
of height above ground and method of protecting the therm
is secured, since in no other way at possible to obtain rest
different places which shall be comparable with each other a
supply satisfactory materials for the investigation and deve
of comparative climatology.

A desired uniformity is yet far from being a
among the meteorological systems of different co
Thus in Russia the box for the protection of the t
meters is made of zinc, on the supposition that suc
follows more closely the changes of temperature of
than a box of wood. Owing to these international
ties of observation, it is extremely desirable tha
were taken to ascertain, by Joule's method of obs
the approximate errors peculiar to each sort of therm
box, in order that the temperatures of different co
may be compared together in a more satisfactory
than has yet been possible.

Interchanges of temperature among bodies take p
conduction, convection, and radiation. In mete
the most important illustrations of conduction are t
pagation downwards through the earth's strata
changes of the temperature of the surface as it is
during the day and cooled during the night, and t
pagation of the same changes of temperature throu
lowest stratum of the air which rests on the surface.
sand and light loose soils are much worse conduc
heat than clay and dense soils, it follows that loo

ets of sand are subject during the day to higher
ature and during the night to lower temperature near
face than dense soils, and that frosts and extreme
atures do not penetrate so far into loose as into
soils. It is on these differences that some of the
riking features of climates depend. As snow is one
worst conductors of heat, owing to the quantity of air
he interstices among the ice crystals, it protects the
covers by setting a limit to the depth to which the
frosts of the surface penetrate, and by arresting the
of the heat of the soil upwards to the air.

communication of heat from one part of the earth
her by convection is seen on a grand scale in the
and in the current of the ocean. It is seen also in
ending and descending currents of the atmosphere
here, which have their origin in the daily and
l changes of temperature to which the surface of the
subject. The direct and beneficial effect which
from atmospheric and oceanic circulation is a more
distribution of temperature over the globe, thus
ting the regions of the polar regions and the heat
tropics.

interchange of heat is constantly going on among
exposed to each other, whatever be their tempera
This mode by which heat is communicated from
dy to another is called radiation. Radiant heat
ls in straight lines, diverging in all directions from
rce, is only in a limited degree influenced by the
ough which it passes, and is not diverted from the
t course by the wind. The intensity is proportional
temperature of the source, and is greater according
degree of inclination of the surface on which the
ll.

en a body be placed in the presence of other bodies,
older and some warmer than itself, it will from this
interchange of temperature receive more heat from
rmer bodies than it radiates to them, and conse
becomes warmer; but it will receive less heat from
lder bodies than it radiates to them, and its
ature consequently falls. This is precisely the
on in which the earth is placed in space. When a
the surface is turned towards the sun, that part of
face receives more heat than is radiated from it:
temperature consequently rises most in that region
for the time is perpendicular to the sun's rays, and
ound the annulus where the inclination of the surface
atest. On the other hand, since the hemisphere
from the sun radiates more heat than it receives
he cold regions of space, the temperature there falls
to the essentially distinct conditions under which
th is placed with respect to radiation, the subject
erally to be divided into two heads, solar radiation
restrial radiation.

r Radiation.—Of the sun's rays which arrive at the
surface, those which fall on the land and solid
generally are wholly absorbed by the thin surface
exposed to the heating rays, the temperature of
consequently rises. Whilst the temperature of the
increases, a wave of heat is propagated downwards
h the soil. The intensity of the daily wave of
ature rapidly lessens with the depth at a rate
ding on the conductivity of the soil, until at about 1
low the surface it ceases to be measurable. Part of
at of the surface layer is conveyed upwards through
by the convection currents which have their origin
heating of the lowermost stratum of air in direct
with the heated surface of the land.

gether different is the influence of the sun's rays on
In this case the sun's heat is not all, indeed very
n all, arrested at the surface, but penetrates to a
considerable depth. The depth to which the influe
the sun is felt has been shown by the observations
during the cruise of the "Challenger" to be, ro
speaking, about 500 feet below the surface of th
The rate at which, in perfectly clear water, this h
distributed at different depths is a problem that h
yet been worked out. Since water is a bad conducto
heat thus distributed does not, as takes place with
to land, penetrate to still lower depths by conductio
only by different densities prevailing at the same
whether these different densities be due to di
temperatures or different degrees of salinity. Th
of the more important distinctions between lan
water surfaces in their bearings on climate is that
all the sun's heat falling on land is arrested on the s
whereas on water it is at once diffused downward
great depth. In examining temperatures of the sea
at different depths, it is surprising to note the r
with which changes of temperature are felt at consi
depths, especially in cases when the temperature of
rises rapidly, accompanied with strong sunshine.

In shallow water the sun's heat raises the tempe
much higher than that of deep water, this being
from the consideration that nearly the whole of th
heat which falls on the surface is utilized in raisi
temperature of the shallow layer of water; in
words, it is, so to speak, concentrated through a
depth of water instead of being diffused through
depth.

Surface Temperature of the Sea.—The importan
knowledge of this datum of meteorology will be
recognized when it is kept in view that three fou
the earth's surface is water, that the temperature
air resting on this surface is in close relation
temperature of the surface, and that the latter has, t
the intervention of the winds, direct and imp
bearings on the temperature of the air over large p
of the land surfaces of the globe. During the
1859-63 Captain Thomas, while engaged on the su
the islands on the north-west of Scotland, made o
tions of the temperature of the surface of the se
hour of the day at all seasons, and with su
frequency for the determination of the diurnal ra
the temperature of the surface. The daily mi
0°·17 below the mean, occurred near 6 A.M.; the ma
reached about 11 A.M., the maximum, 0°·13 abo
mean, between 3 and 4 P.M., and the mean again
before 2 A.M. Thus the daily oscillation of the temp
of the surface of the sea amounted on the north-
Scotland only to 0°·3. In lower latitudes the am
the daily fluctuation is somewhat larger, but everyw
is comparatively small, if care be taken to ma
observations properly, or at a distance from land,
the influence of the heated or cooled land is not
to vitiate the results.

During the voyage of the "Challenger" a co
system of meteorological observations, including th
perature of the surface of the sea, was made eve
hours as part of the scientific work of the cruise.
are now being discussed, and the writer of this ar
by permission of the Lords Commissioners of
Treasury, allowed to use such of the results as hav
already arrived at.

The diurnal march of the temperature of the su
the North Atlantic has been determined from obser
made on one hundred and twenty-six days from M
August 1873 and in April and May 1876, the
latitude of all the points of observation being nearly
and the longitude 12° W. The following variation
the mean show the phases of this diurnal oscillation

M. −0·24	10 A.M. 0·06	6 P.M.	0·26
„ −0·33	Noon 0·24	8 „	0·02
„ 0·29	2 P.M. 0·47	10 „	0·19
„ −0·12	4 „ 0·47	Midnight	0·35

mid Atlantic, about 30° N. lat., where the sun's strong, and at the time of the year when the sun is f the equator, the diurnal fluctuation of the temperat the surface is only 0°·80. It is highly probable where over the ocean does the mean daily fluctuation emperature of the surface quite amount to a degree. nall daily fluctuation is a prime factor in meteorology, larly in discussions relating to atmospheric pressure nds.

mperature of Air over the Open Sea. The following he daily march of the temperature of the air over rth Atlantic on a mean of the same one hundred enty-six days for which the temperature of the sea n given:—

M. −1·13	10 A.M. 0·75	6 P.M.	0·73
„ −1·40	Noon 1·15	8 „	0·30
„ 1·41	2 P.M. 1·80	10 „	0·80
„ 0·21		Midnight	1·02

mplitude of the daily fluctuation of the air is thus or nearly four times greater than that of the r which it lies. During the same months the enger" was lying near land on seventy-six days servations made on these days show a greater daily of temperature of the air than occurred out in the ea. The minimum, −2°·05, occurred at 1 A.M., and ximum, 2°·33, at noon, thus giving a daily range of The occurrence of the maximum so early as noon is ss occasioned by the greater strength of the sea after this hour, thus maintaining a lower tempera- Part of the increased range of the temperature of as compared with that of the sea was no doubt the higher temperature during the day and the uring the night on the deck of the "Challenger" as ed with that of the air. But, after making allow- r this disturbing influence, it is certain that the ature of the air has a considerably larger daily range nat of the sea on which it rests. The point is one mall interest in atmospheric physics from the im- bearings of the subject on the relations of the air aqueous vapour to solar and terrestrial radiation.

hourly deviations from the mean daily temperature ir at two places, one near the equator and the other north temperate zone, and both near the sea, viz., (6° 8′ S. lat., 106° 48′ E. long., mean temperature and Rothesay (55° 50′ N. lat., 5° 4′ W. long., mean ature 47°·3), are these

During the night in summer the temperature fall tinuously from the effects of terrestrial radiation earliest dawn, when the daily rise in the temperatu in owing to the heat reflected from the upper strata atmosphere, which have begun to be heated and up by the rays of the morning sun. It will be ob that the time of the daily minimum temperature earliest in high latitudes and latest in low lat During winter, on the other hand, the minimum te ture takes place in several regions some time before At this season the two chief causes on which cha temperature depend are the sun and the passage of c and anticyclones; and it is probable that those cases the minimum occurs markedly before the dawn are not occasioned by purely local disturbing causes, the mean diurnal times of occurrence of the char temperature which accompany the great atmospher turbances of cyclones and anticyclones.

In July the daily maximum temperature occurs ge from 2 to 4 P.M. At places, however, near the sea, are within the immediate influence of the sea bree in places at some distance from the sea, such as Ca where the wind, being essentially a sea wind, atta greatest daily velocity and the sky at the same much clouded, the maximum occurs nearly two earlier. In high situations, such as the St Bernard H the highest daily temperature also occurs nearly tw sooner than on the plains below. In the winter the maximum is about an hour earlier than summer.

In investigating the daily curves of temperatu David Brewster drew several interesting conclusio them. By dividing the daily curve of temperature, from the mean of the year, into four portions, at the representing the two daily means and the two ex he showed that the four portions approximate to pa in which the temperatures are the abscissæ and th the ordinates. The correspondence between the o and calculated results is so close that the differe not in any case exceed a quarter of a degree Fah This interesting result is true for places at wh horizon is open all round, so that no shadows o trees, or buildings fall on the places where the meters are kept during the day. If a hill rises

of the place, by which the sun's rays are never ted, it exercises little, if any, influence on the ations; but if one or more hills obstruct the rays un after it has risen above the horizon, such obstruc- ffects the temperature while, and for some time the position in which the thermometer is placed is from the sun.

wster further mad th important remark that the of observations made at any pair of hours of the ame, such as 8 A.M and 8 P.M., 9 A.M. and 9 P.M., es not differ much from the mean temperature of y. The pairs of hours which approximate closest to ie daily mean are 9 A.M. and 9 P.M., 10 A.M. and 10 A.M. and 3 P.M., and 4 A.M and 4 P.M. The mean hours at equal intervals from each other gives a still closer to the true mean temperature.

rganizing any system of meteorological observation, by which tended to develop the climatology of the country, the de- ation of the hours of observation is a question of the first nce. If only two observations be made daily the best hours M and 9 P.M., or 10 A.M. and 10 P.M., and if there be four tions the best hours are 3 and 9 A.M and 3 and 9 P.M., d 10 A.M and 4 and 10 P.M If there be three observa- e best hours are 9 A.M and 3 and 9 P.M., or 10 A.M nd 10 P.M., but in these cases it is essential that the tions of a minimum thermometer be added to the tempera- servations. These hours are further strongly recommended consideration that they are approximately coincident with tual places of atmospheric pressure, an exact knowledge h lies at the root of nearly all climatological inquiries. ree equidistant hours which have been adopted in several s, viz., 6 A.M. and 2 and 10 P.M., are only good as regards perature, not as regards atmospheric pressure. With re- two daily observations, the hours 8 A.M. and 1 P.M., which en adopted in some countries, are singularly unsuitable furnishing of the observational data required in the de- ent of the climatologies of these countries; and, what is re serious in a science where international co-operation is so tively demanded, these observations cannot be used with sfaction in such deeply important inquiries as the com- climatologies of Europe

times of occurrence of the highest, lowest, and daily temperatures and the amount of the daily of temperature, are a great degree influenced by ver t want of covering of the earth's surface on the air rests. When the ground is covered with tion, the wh of the solar heat falls on the ble covering; and, as none falls immediately on the s temperature does not rise so high as happens where s no vegetable covering to shade the surface from n. The temperature of plants exposed to the sun is high a that of exposed soil in the vicinity. As s forests, the four diurnal phases of temperature later than in the open country, and the maximum minimum are less decided; and, since the maximum nature of the air in forests falls short of the maximum open to a considerably greater extent than the um under the above the minimum in the open, ows that the mean temperature of the air in forests s than that the open country adjoining. The of the difference is that the chilling effects of rnal radiation penetrate lower down among the trees lo the heating effect of solar radiation; and as the not heated directly by the sun its temperature is and consequently that of the air over it is also A cleared space in a forest, sheltered by the sur- ng trees, but open to the sun, has a warmer and r atmosphere in spring and summer and very much r in autumn than prevails in the open country ng, and has also the diurnal differences of range ar to a warmer and moister atmosphere.

of the most important elements of climate is dis- by the difference between the hour of lowest and ur of highest mean temperature respectively, or, as it is usually expressed, by the daily range of tempe We have seen that as regards the sea in the north- Scotland the difference is only 0°·3 and in the A about 30° N. lat. 0°·8, and that probably the diurnal of temperature of the surface of the sea nowhere amo a degree. In the same part of the Atlantic the daily of the temperature of the air resting on the ocean and on the sea near land 4°·4. On advancing on th the daily range of temperature rapidly increases, a rate of increase is greatly augmented when an position is arrived at to which any sea breezes th prevail do not extend.

The true daily range of temperature is stated by vations made with maximum and minimum thermo Generally speaking, the amount of the range incre the latitude is diminished, and as the distance from is increased, but above all it increases in proportion dryness of the climate.

The differences of this vital element of climate are strikingl in the meteorology of India In the *Report* for 1880 the fo are the mean daily ranges of March of that year at a few at Goa 5°·4, Bombay 11°·2, Kurrachee 23°·5, Jacobabad 37 Pachbudra (lat 25° 55′ N., long. 72° 18′ E.) 41°·3. In case, undoubtedly one of the greatest mean daily ranges perature meteorology has yet recorded, the mean of the d 103°·4 and of the nights 62°·1. As March is altogether the season of the north-east monsoon, the general drift wind over western India, when these are situated, is f interior towards the sea, subject as regards Bombay and the influences of the land and the sea breeze. On the othe in June, when the south-west monsoon has fairly set following are the mean daily ranges of temperature at t places: at Goa 5°·6, Bombay 8°·2, Kurrachee 10°, Jacobaba and Pachbudra 24°·1. These show in a striking man powerful influence of the moister atmosphere spread over I the south-west monsoon, under which the daily range of t ture falls at Kurrachee from 23°·5 to 10°, and in the exc and climate of Pachbudra from 41°·3 to 24°·1 In th climates of the basin of the Indus, whilst the rainfall both i and in June is practically nil, yet the relative humidity atmosphere is widely different. Thus the humidities for Ma June respectively at 4 P.M., when the temperature is ne maximum for the day, are 48 and 77 for Kurrachee, 18 an Jacobabad, and 11 and 36 for Pachbudra. It is not so m amount of cloud that determines the degree of fierceness of t heat in these climates as the relative humidity, or the dr the air, as pointed out by Strachey in 1866. Thus at Ja less than half the amount of cloud appears in the sky i as compared with March, but the relative humidities and 18, and the daily range of temperature 27°·6 and 37 we except the dry arid wastes of Persia and Arabia, perhaps no other region of the globe where the daily temperature approaches that of the valley of the Indus. in the dry climates of such places as Sacramento (Ca in summer it amounts only to about 30°, at Madrid to 2 Jerusalem 24°. In central districts in the south of it is about 20°; farther north it falls to 15°; and in the in the north, whose climate is strictly insular in its ch the summer daily range is only 10°. In Arctic regio as Spitzbergen and Bootha Felix, the range in winte from 0°·0 to 1°·0; in May, when the sun has reappea continues to rise and set, it rises to 14°; but in July, w sun does not set, the range sinks to 10°.

But maximum and minimum thermometers n show the mean daily range of temperature, they a of great utility in giving observations for the determ of mean temperature. The mean temperature n accepted as the mean of the twenty-four hourly o tions of the day. If with such a system of obse daily readings of the maximum and minimum therm be compared, the value of the latter observati questions of mean temperature may be arrived at. series of observations of this description have bee at many places. The following shows a comparison mean of maximum and minimum daily temperatur means from observations made twenty-four times the former exceeding the latter means in nea cases:—

	Spring.	Summer.	Autumn.	Winter	Year
.....	- 0·3	0·2	- 0·2	0·2	0·2
a	1·0	0·7	0·7	0·9	0·8

e results show remarkable uniformity, and it may rred from them that mean temperatures deduced aximum and minimum observations are about half e above the true mean temperature. In general logical inquiries, observations with these thermo have the strong recommendation of supplying from tions taken once a day the data for the determina- the mean temperature and mean daily range of es; to which falls to be added the further advantage g results more uniformly comparable for different han could be afforded by observations made with a thermometer at any single hour or pair of hours

y Variation of the Humidity of the Air. The envelope surrounding the earth is composed of mospheres, quite distinct from each other,—an here of dry air and an atmosphere of aqueous The dry air, which consists of oxygen and n, is always a gas, and its quantity remains constant; aqueous vapour does not continue permanently in eous state, and the quantity present in the air is, ceaseless processes of evaporation and condensation, tly changing. If the aqueous vapour remained ently and unchanged in the atmosphere, or were le to be condensed into cloud or rain, the mixture become as complete as that of the oxygen and of the air. The equilibrium of the vapour atmo however, is being constantly disturbed by every of temperature, by every instance of condensation, the unceasing process of evaporation. Since dry ther materially obstructs the free diffusion of the s vapour, it follows that the law of the independent e of the vapour and of the dry air of the atmosphere good only approximately. The aqueous vapour, r, constantly tends to approach this state. Since, e independent and equal diffusion of the dry air aqueous vapour is, owing to these disturbing causes, reached, the important conclusion follows that the eter can never indicate more than the local humidity place where it is observed. Hygrometric observa- an therefore be regarded only as approximations to ndication of the quantity of aqueous vapour in the here over the place of observation. It is, however, lded that, while in certain cases the amount of vapour d is far from the truth, yet in averages, particularly erages, a close approximation to the real amount is if the hygrometer be at all tolerably well exposed efully observed.

eous vapour is constantly being added to the air he surfaces of water, snow, and ice, from moist s, and from plants. The rate of evaporation es with an increase of temperature, because the y of the air for vapour is thereby increased. The here can contain only a certain definite amount of according to the temperature; when therefore the its full complement of vapour, or when, in other it is saturated, evaporation ceases. Thus the rate oration is greatest when the air is driest or freest from vapour, and least when the air is nearest the po saturation. Since currents of air remove the moist substitute drier air over the evaporating surfaces, ev tion is much more rapid during wind than in calm we As air expands under a diminished pressure, its tempe consequently falls, and it continues to approach nea the point of saturation, or become moister; and, contracts under an increased pressure, its temperatur and it recedes from the point of saturation or be drier. Hence ascending currents of air become m with every addition to the ascent, and descending cu drier as they continue to descend. Thus as winds a the slopes of hills they become moister, but when have crossed the summit and flow down the othe they become drier in proportion to the descent, and changes may be experienced from extreme dryn saturation in the same mass of air, which all the tim practically had its amount of aqueous vapour neither to nor diminished.

In an atmosphere of air and aqueous vapour per mixed, the elastic force of each at the surface of the is the pressure of each In this case the elastic fo aqueous vapour would be the pressure of the whole v in the atmosphere over the place of observation. pressure is expressed in inches of mercury of the baro If we suppose the total barometric pressure to be 3 inches, and the elastic force of vapour to be 0·745 the pressure or weight of the dry air, or air proper, be 29·255 inches, and of the aqueous vapour 0·745 From this it follows that the elastic force of vapou be regarded as indicating the quantity of aqueous v in the air at the place of observation, or it may be nated the absolute humidity of the air.

The diurnal variation in the elastic force of vap the air is seen in its simplest form on the ope Grouping together all the hygrometric observations on board the "Challenger" on the North Atlantic distance from land, from March to July 1873 (eight days), we have for that time a mean elastic force of inch, and the following diurnal variation:—

	Inch		Inch.		In
2 A.M	015	10 A.M.	+ ·004	6 P.M.	+ ·0
4 ,,	020	Noon	+ ·017	8 ,,	+ ·0
6 ,,	- ·016	2 P.M.	+ ·020	10 ,,	- ·0
8 ,,	·007	4 ,,	- ·017	Midnight	+ ·0

Hence the minimum (- ·020 inch) occurs at the when the temperature of the surface of the sea a resting over it falls to the daily minimum; it the to the mean a little after 9 A.M., and to the daily max (+ ·020 inch) at 2 P.M., when the sea and air are als the daily maximum, and falls to the mean shortly 9 P.M.

Treating the observations made near land b "Challenger" during the same months, the follow the diurnal variation disclosed:—

	Inch		Inch.		In
2 A.M	003	10 A.M.	+ ·014	6 P.M.	·
4 ,,	- ·009	Noon	+ ·011	8 ,,	·
6 ,,	- ·010	2 P.M.	+ ·007	10 ,,	- ·
8 ,,	·003	4 ,,	+ ·015	Midnight	·

The disturbance induced by proximity to land distribution of the aqueous vapour in the lower st the atmosphere is very striking. The maximum minimum no longer follow the corresponding phases temperature of the surface of the sea and of the air. disturbing agents are the sea and land breezes and effects. Under the influence of the land breeze th of the minimum humidity is delayed till about 6 A.M under the influence of the sea breeze and its effe amount of the aqueous vapour shows a secondary min from noon to 2 P.M. It is to be here noted that this m

m occurs at the hours of the day when the surface and is most highly heated, the ascending current ed air rising from it therefore strongest, and the g breeze from the sea toward the land also strongest. does not admit of a doubt that the diminution in ount of the aqueous vapour noted on board the enger" near the shore point to an intermixture e air forming the sea breeze of descending thin ents or currents to supply the place of the masses emoved by the ascending currents which rise from ted surface of the land At Batavia, on the north f Java, and at Bombay, the aqueous vapour is also to a secondary minimum during the warmest hours day.

ing the summer months the secondary minimum is arked at inland places such as Peking, Nertchinsk, l, Tiflis, and Ekaterinburg, but the time of its nce is about two hours later than it is over the Atlantic Over all these places at this season the ng current from the heated land in the interior of very strong On the other hand the lowering of ount of aqueous vapour scarcely if at all appears as re in the summer climate of St Petersburg, and all in that of Sitka, where the sea breeze is equally on that feature of the climate of the district

excessively dry tumble and not climate of Allahabad, in e diurnal minimum of the aqueous vapour occurs from to 6 P.M., the time of absolute minimum being 2 and During all other hours of the day the amount of the above the mean a secondary minimum occurring from A.M. At Allahabad at this time, the absolute maximum apour pressure occurs at 8 A.M. Quite similar to this is nal distribution of the aqueous vapour in July at Lisbon nica, the minimum occurring from 10 A.M. to 8 P.M. At of the year the climate of this part of the peninsula is dry and the rainfall insignificant in amount As the nce between the high atmospheric pressure so characteristic of the meteorology of the Atlantic in summer and the tively low pressure over the continents southward and d, the winds are almost wholly north-westerly. In this on it is instructive to note that the time of maximum pressure is from 1 to 7 A.M., when the velocity of the wind the minimum, and the chief minimum vapour pressure ors to 1 P.M., when the velocity of the wind and ascending rent reach the daily maximum The results show that rmation in the vapour pressure during the hours when ature is logically, which characterizes the climates of large the globe, is due to descending air filaments or currents, ences only accompany the ascending currents that rise from ted land

neva during the summer months the vapour curve exhibits ly minima very strongly marked, the one shortly before and the other from 2 to 4 P.M., and two maxima, one to 11 A.M. and the other from 6 to 10 P.M., and with e diurnal variations of cloud are in accordance. The ly marked features of the vapour curve at Geneva are y due to the size of the lake, which is large enough to e to a decided breeze during the day from the lake all its horizon and during the night to a breeze from the land ed upon the lake On the setting in of the breeze, the air composing it having been for some time resting on e, is rather moist and thus one of the daily maxima is about from 8 to 11 A.M. As the breeze continues the air ng it is necessarily drawn from the higher strata of the here more copiously than in different situations; and, having quired more cool dryness in the descent and having blown e lake for too short a distance to materially influence its e, the air becomes constantly drier, till the minimum to 4 P.M. is reached. The lake breeze thereafter begins to h in force, and the air consequently becomes moister till the um vapour pressure of the day occurs when the lake breeze ay and the land breeze has not yet sprung up. In the months when these breezes do not prevail, the curve of vapour pressure shows only one zero maximum and minimum.

relative humidity of the atmosphere must not be nded with its vapour pressure or absolute humidity. lative humidity, or, as it is more frequently called, midity, of the air is the degree of its approach to ion. Complete saturation is represented by 100 and air absolutely free of vapour by 0, the latter st things never occurring in the atmosphere, a humid 10 being of rare occurrence even in such arid regi those of Arabia. The great significance of this elem climate is in its relations to the diathermancy of t and consequently to solar and terrestrial radiation. supposed that perfectly dry air would allow rays o to pass through it with at most only a very increase to its temperature therefrom. Let, howe little aqueous vapour be added to it, a partial obstr to the passage of radiant heat is offered, and the te ture of the mixture, or common air, is sensibly Hence, other things being equal, the less the amo vapour the more are the effects of radiation felt, greater the heat of the days and the cold of the The mere amount of vapour in the air does not det the degree of radiation, but it is the amount of together with a certain temperature in other word absolute and relative humidity of the air taken toge that determines the heating power of the sun a degree of cold produced by terrestrial radiation.

The diurnal variation of the relative humidity different from that of the vapour pressure, and p features of the simplest character. The following diurnal variations from the mean humidity 80 ov North Atlantic, from the "Challenger" observati 1873:—

2 A.M.	+2	10 A.M.	1	6 P.M.	−
4 ,,	+2	Noon	−2	8 ,,	
6 ,,	+1	2 P.M.	3	10 ,,	+
8 ,,	0	4 ,,	2	Midnight	+

Thus the maximum humidity occurs from midnig 4 A.M., or when the daily temperature is at the min and the minimum humidity at 2 P.M., when the te ture is at the maximum, the curve of humidity bein inverse to that of the temperature. With two modifications this is the diurnal humidity curve climates and seasons. In the calm which interve the morning between the land and the sea bree humidity continues high, or even increases, though time the diurnal increase of temperature has alre in. The other modification is seen in the humidity for Nertchinsk and Barnaul during winter, these being not inverse but coincident with the daily cu temperature. In the climates of Central Asia in the amount of vapour is very small, and the incre the relative humidity during the day is probably occa by the more active evaporation from the snow duri day and the stillness of the air favouring the accum of aqueous vapour near the surface of the earth.

Next to the winds, the aqueous vapour of the sphere, in the diverse ways in which in different lo it is distributed through the hours of the day, pla most important part in giving to the different parts globe its infinitely diversified climates.

Dew.—Dew is deposited over the earth's surf comparatively clear and calm nights. As the cool terrestrial radiation continues, the temperature of on the surface is gradually lowered to the dew-poi when this point is reached the aqueous vapour be be condensed into dew on their surfaces. The q deposited is in proportion to the degree of cold pr and the quantity of vapour in the air. Dew deposited in cloudy weather, because clouds obstru escape of heat by radiation, nor in windy w cause wind continually renews the air in contac the surface, thus preventing the temperature from sufficiently low. When the temperature is below 3 freezes as it is deposited, and *hoar-frost* is produced dew-point practically determines the minimum temp

night,—because if the temperature falls a little the dew-point the liberation of heat as the vapour lensed into dew speedily raises it, and if it rises the loss of heat by radiation speedily lowers it. onsideration suggests an important practical use of grometer, it being evident that by ascertaining the int the approach of frost or low temperature likely re vegetation may be foreseen and provided against.

rnal Oscillations of the Barometer.—The general er of the daily oscillations of atmospheric pressure wn by the two curves of fig. 2. The solid ives the mean oscillation for Bombay and the

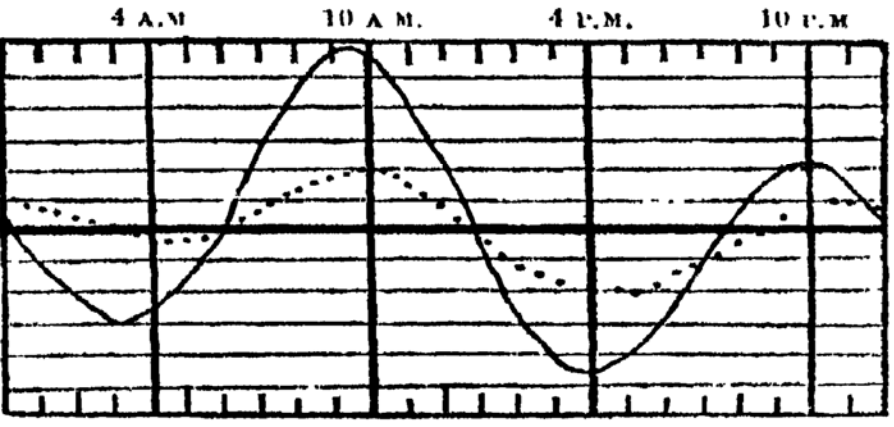

FIG. 2.—Daily Oscillations of Atmospheric Pressure.

line that for Vienna, these two curves being to extent typical of diurnal barometric oscillations in l and temperate regions as regards the two maxima nima and the time of their occurrence.

ries of twelve maps of the globe were prepared for showing, for all stations whence observations have btained, the deviations at noon, 2 P.M., 4 P.M., reenwich mean time, from the mean daily pressure: ar lines were drawn indicating the positions of the ily maxima and minima at these hours. For fully rth and south of the equator the lines of maxima nima run north and south, but in higher latitudes irections are changed, and the changes are chiefly uous as regards the A.M. maximum and the P.M m. Thus, for example, at 6 P.M. (G. M. T.) the P.M. minimum is for the latitude of London near long.; in 30° N. lat. it is in 35° W. long., in which runs south as far as 30° S. lat.; its course thence outh-westwards to near the Falkland Islands, 60° g. Hence in June the P.M. minimum occurs about hours earlier in the Falkland Islands than to the west of Ireland, thus showing in a striking manner uence of season on this phenomenon. In the middle igher latitudes in summer, proximity to the sea the time of occurrence of the A.M. maximum and M. minimum; whilst in continental situations the aximum occurs much earlier than in lower latitudes, e P.M. minimum nearly as late as at places near the In cases where the lines of maxima and minima region such as southern and western Europe, whose is diversified by large tracts of land and sheets of the deflexions are of a remarkable character.

retardation of the time of occurrence of the A.M. um is greatest in situations which, while eminently in character, are at the same time not far from an ve tract of land. Of this Holland presents the best le in Europe; and there the A.M. maximum, which s occurs at 8 A.M., does not occur at Utrecht till .M., at Amsterdam till 12.30 P.M., and at Helder till There is thus as regards the same diurnal phenoin June a difference of six hours between Paris and . Sicily and the south of Italy on the one hand adrid on the other present also the most striking sts. Again at Sitka (56° 50′ N. lat., 135° W. long.), has one of the most truly insular climates in the the A.M. maximum is delayed to 2.30 P.M.; whereas at Astoria, ten degrees to southward, it occurs a A.M., and at Fort Churchill, in Nevada, as ea 7 A.M. There is thus as regards the same phen a difference of 7h 30m between Sitka and Fort Chu

From hourly observations made in this month base, the top, and two intermediate points on Washington (N. H.) it was found that the time of rence of the A.M. maximum at the base of the mo which is 2898 feet above the sea, was 8 A.M.; a feet, 10 A.M.; at 5533 feet, 11 A.M; and at th 6285 feet, noon. Hence, as regards the time of rence, the influence of an isolated mountain like Washington brings about a result similar to w observed in insular situations. But the analogy i closer. In insular climates the minimum in the morning is very greatly in excess of that in the afte and the same relation is observed on the top of Washington, where the former is - 0·020 inch a latter - 0·004 inch. Again in continental climat minimum in the early morning is much the smaller two, and the same relation was observed at the base mountain, where the observed minima were respe 0·006 inch and 0·020 inch. The differences presen the daily curve of pressure at the top as compared that at the base of the mountain have their explana the effects which follow the diurnal range of tempe As the temperature is at the minimum at the time pressure in the morning, the atmosphere is more com in the stratum between the base and the top, and quently the barometer at the top reads relatively As the temperature continues to rise during the d stratum of air above the base of the mountain ex thus placing more air above the barometer at the that, while at the base pressure begins to fall at at the top it continues to rise till noon, simply fr mechanical upheaval of the air owing to the higher te ture. In the afternoon, when the minimum at th falls to - 0·020 inch, it is only 0·004 inch at the to relatively higher pressure at the top being due to exp from temperature. The peculiar feature of the p curve at the top is essentially a temperature effect

The diurnal oscillations of the barometer occu over the open sea and over the land surfaces globe. The atmosphere over the open sea, a shown, rests on a floor or surface subject to a range of temperature so small as to render that temp practically a constant both day and night. This con tion leads to the vital and all important conclusion t diurnal oscillations of the barometer are not caused heating and cooling of the earth's surface by sol terrestrial radiation and by the effects which follo diurnal changes in the temperature of the surface, b they are primarily caused by the direct and ind heating by solar radiation, and cooling by nocturna tion to the cold regions of space, of the molecules air, and of its aqueous vapour. These changes perature are instantly communicated through th atmosphere from its lowermost stratum resting earth's surface to the extreme limit of the atm which the light of meteors proves to be not less th miles. There are important modifications affecti amplitude and times of occurrence of the four pr phases of the phenomena observed over land surfa temperature of which is being superheated during and cooled during the night; but it is particularl noted that the barometric oscillations themselves a pendent of any changes of temperature of the which the atmosphere rests.

Let us first look at the phenomena in the simple as found in the Pacific, or in the midst of the larges

of the globe. The following are the mean varia- pressure from observations made on board the enger," September 1 to 12, 1875, in mean latitude . and long. 150° 10′ W., the mean being 29·928

	Inch.		Inch.		Inch.
M.	0·012	10 A.M.	0·032	6 P.M.	0·028
,,	0·022	Noon	0·006	8 ,,	0·004
,,	0·003	2 P.M.	0·013	10 ,,	0·013
,,	0·028	4 ,,	0·035	Midnight	0·012

ost striking feature in the e oscillations is the ude of the range from the A.M. maximum to the minimum, amounting to 0·087 inch, and the rapidity fall from 10 A.M. to 2 P.M. The same feature in all means deduced from observations made at 2° on each side of the equator.

n October 12 to 22, 1875, in mean lat. 35° 1′ S., long. 5′ W., the mean atmospheric pressure was 30·298 and the difference between the A.M. maximum and minimum was only 0·036 inch; and from July 12 1875, in mean lat. 36° 16′ N. and long. 156° , the mean pressure was 30·328 inches, and the e between the A.M. maximum and P.M. minimum 0·025 inch. Thus, with a mean pressure in the about lat. 35° 36° N. and S. much greater than equator, the oscillation is much less, being in the Pacific less than a third of what occurs near the . Similarly, this oscillation is small (or even smaller) ich pressure areas in the North and South Atlantic ared with the same oscillation near the equator.

well known that aqueous vapour absorbs the heat the air considerably more than does the dry air of sphere, how much more physicists have not yet ly determined. Consequently air heavily charged queous vapour will be heated directly by the sun's they pass through it in a greater degree than atively dry air is. Now it is shown further on that evailing surface winds outflow in every direction areas of high mean pressure in the Atlantic and about lat. 36° N. and S. Since, notwithstanding, same continues high, it necessarily follows that the ssure is maintained by an inflow of upper currents, the low descending movement of the air connects owing upper currents with the outflowing prevailing of the surface, it follows that the air over high- areas is very dry, and that it is driest where is highest and the high-pressure area best defined. over the best defined anticyclonic regions the air will ed in temperature through all its height by ay of the sun.

the other hand, between these high-pressure areas of t one there is a belt of comparatively low pressure which the north and south trades pour their ncessingly. The atmosphere of this belt of low than highly saturated with aqueous vapour rises in a vast ascending stream of moist air to the regions of the atmosphere. These equatorial regions e out to the sun a highly saturated atmosphere g to a very great height. It is in these regions re that the atmosphere will be most highly heated sun's heat rays as they pass through it. One of st striking facts of meteorology is the suddenness hich this barometric oscillation increases in amplitude ering on these parts of intertropical regions; and pidity with which it amplitude diminishes on ng on the high-pressure regions of the horse s is equally striking. The following are the mean ons in the middle regions of the four great oceans t. 36° from the A.M. maximum to the P.M. minimum he time of the year in each case when the sun est in the heavens.—South Pacific, 0·036 inch; North Pacific, 0·025 inch; South Atlantic, 0·02 and North Atlantic, 0·014 inch. These amp diminish as the ocean becomes more land-locke continents, or as the anticyclonic region becomes defined and currents of air are poured down more from the higher regions of the atmosphere.

If the temperature of the whole of the earth's atm were raised, atmospheric pressure would be dimi for the simple reason that the mass of the atm would thereby be removed to a greater distance fr earth's centre of gravity. Quite different results, h would follow if the temperature of only a section earth's atmosphere were simultaneously raised, such section comprised between long. 20° and 60° W immediate effect would be an increase of bar pressure, owing to expansion from the higher tempe and a subsequent effect would be the setting in ascending current more or less powerful, according differences between the temperature of the heated and that of the air on each side. These are esse the conditions under which the morning maxim afternoon minimum of atmospheric pressure take pl

The earth makes a complete revolution round in twenty-four hours, and in the same brief inter double crested and double troughed atmospheric tide makes a complete circuit of the globe. The w the diurnal phenomenon of the atmospheric tides i fore rapidly propagated over the surface of the eart east to west, the movement being most rapid in equ regions, and there the amplitude of the oscillat greater than in higher latitudes under similar atmos astronomical, and geographical conditions. Owing rapidity of the diurnal heating of the atmosphere sun through its whole height, some time elapses bef higher expansive force called into play by the incr temperature can counteract the vertical and latera ance it meets from the inertia and viscosity of t Till this resistance is overcome, the barometer co to rise, not because the mass of atmosphere over increased, but because a higher temperature has in the tension or pressure. When the resistance ha overcome, an ascending current of the warm air sets tension begins to be reduced, and the barometer fa continues to fall till the afternoon minimum is r Thus the forenoon maximum and afternoon minim simply a temperature effect, the amplitude of the osc being determined by latitude, the quantity of a vapour overhead, and the sun's place in the sky.

All observations show that over the ocean, latitu latitude, the amplitude of the oscillations is greate atmosphere highly charged with aqueous vapour a in a dry atmosphere. It is also to be noted that elevated situations, particularly in tropical region amplitude is greater proportionally to the whole p than at lower levels. This is what is to be expecte the law of radiant heat by which more of the heat the sun is absorbed by the air, and particularly aqueous vapour, mass for mass, in the higher than lower strata.

When the daily maximum temperature is past, a temperature has begun to fall, the air become condensed in the lower strata, and pressure conse at great heights is lowered. Owing to this lower p in the upper regions of the air, the ascending which rises from the longitudes where at the ti afternoon pressure is low flows back to eastwar increasing the pressure over those longitudes wh temperature is now falling. This atmospheric qua movement occasions the P.M. increase of pressure, reaches the maximum from 9 P.M. to midnight, ac

ude and geographical position. This maximum is
caused by accessions to the mass of the atmosphere
d, contributed by the ascending currents from the
les of the afternoon low pressure immediately to
rd.

idnight and the early hours of morning advance,
ontributions become less and less and at length
ltogether, and pressure continues steadily to fall.
tween the time when the increase of pressure from
rflow through the upper regions of the atmosphere
nd the time when pressure increases from the heat
rect or indirect, of the returning sun, or during the
of the night when the effects of nocturnal radia
e the maximum, pressure is still further reduced
nother cause. Radiation towards the cold regions
e takes place, not only from the surface of the
ut also directly from the molecules of the air and
eous vapour. The effect of this simultaneous cool
he atmosphere through its whole height is neces
diminution of its tension. Since this takes place
re rapid rate than can be compensated for by any
ical or tidal movement of the atmosphere from the
adjoining, owing to the inertia and viscosity of the
ssure continues to fall to the morning minimum.
inimum is thus due, not to the removal of any of
s of air overhead, as happens in the case of the
on maximum, but to a reduction of the tension or
e of the air consequent upon a reduction in the
ature through radiation from the aerial molecules
s the cold regions of space. In the open ocean the
g minimum is largest in the equatorial regions, and
nishes with latitude; but the rate of diminution
titude through anticyclonic and other regions is
ly less and more uniform than in the case of the
n minimum.

mplitude and times of occurrence of the phases of
rual barometric tides are subject to great modifica
ver the land. The amplitude of the oscillation
e morning maximum to the afternoon minimum is
where the atmosphere is driest and the sky
, and least where the atmosphere is highly saturated
e sky more frequently and densely covered with
being thus generally the reverse of what is observed
place over the open sea. The meteorology of India
the most striking illustrations of this remark. At
in April during the dry atmosphere and clear
f the north-east monsoon, the oscillation is 0·118
ut in July during the humid atmosphere and
skies of the south-west monsoon it falls to 0·067
In the Punjab, where the air is drier, it is much
rising in exceptional years, such as 1852, to 0·187
The much greater amplitude of this oscillation on
compared with the open sea is entirely due to the
of the earth. By this heating of the surface the
trata of the air become also highly heated and the
is increased; and, since the air does not expand
ertically and laterally, from its inertia and viscosity,
rometer rises. When, however, the resistance is
ne, the ascending current which sets in is stronger
to its higher temperature. Since this higher
ature which has its origin in the superheated
is in addition to the direct heating of the air by
at rays of the sun as they pass through it, the
g maximum and the afternoon minimum over land
h more extreme than over the open sea. It follows
is oscillation is much larger over land, and largest
ates where insolation is strongest.

aces already referred to where the morning maxi
greatly retarded, such as Helder, Sitka, Valentia,
almouth, the afternoon minimum in the summer
months is singularly small, so small indeed that it
not fall so low as the mean pressure of the day.
peculiarity in the diurnal barometric tide is in all p
ability due to their insular position to the westward
a more or less extensive tract of land, by which a t
overflow is propagated through the upper regions from
continental towards the insular situations. This t
overflow receives its impulse from the ascending cur
from the land, which rises sooner and stronger from inl
than from insular situations. On the other hand, on
open sea, and away from land in regions where the m
ing maximum and afternoon minimum are both small,
minimum always falls below the mean of the day, and
time of occurrence of the maximum is not retarded
the case in insular situations. A map of deviations f
the daily mean pressure of the morning minimum
summer shows, as regards the middle and higher latitu
that it is greatest near the sea, and least in inland
tinental situations. Indeed in the interior of the Old W
continent the dip in the curve in the early morning i
small that the minimum does not fall below the daily m
pressure, but at most places remains considerably above
The same relations are seen in north-western Europe, wh
the morning minimum is 0·020 inch at Valentia
Falmouth, −0·018 inch at Helder, and 0·012 inch
Amsterdam, whilst at Kew it is only 0·002 inch. Fr
its compact form and relations to the surrounding oce
the Spanish Peninsula well illustrates the peculiarities
this phase of the pressure. The deviations from the d
mean pressure of the morning minimum are at Lis
0·022 inch and Coimbra −0·011 inch, but at Mad
in the interior +0·009 inch, pressure in the last case,
as happens in the interior of Asia, not falling so low as
daily mean.

The larger minimum near the sea arises from the hig
temperature there during the night as compared w
more inland situations, from which results a tidal overf
through the upper regions from the sea towards the la
as the temperature of the latter falls lower than the
during the night. The effect of this overflow is to red
the pressure over those regions whence it proceeds and
increase it in those regions over which it advances.
shallowing of the morning minimum is greatest in
higher latitudes of continental climates and most compl
at great elevations, where in some cases the minim
vanishes, in other words, where the amount of aque
vapour is small and the time is short during which no p
of the atmosphere overhead is touched by the sun's ra
Since the peculiarity is observable in the curves over nea
the whole continent, appearing even in the low latitu
of Calcutta and Madras, it might be suggested whether
have not evidence here of a vast tidal movement propaga
through the higher regions towards that trough-like sec
of the atmosphere as it moves westwards over the contin
where the temperature of the lower strata of the ai
about the minimum of the day and pressure also ab
the minimum.

Reference has been made under ATMOSPHERE to
smallness of the range from the A.M. maximum to the
minimum in the North Atlantic during summer.
phase in the diurnal distribution of pressure is represen
in fig. 3, which shows for June the mean amount
the oscillation by lines of 10, 20, 40, 60, 80, and
thousandths of an inch, or 0·010 inch, 0·020 inch,
This abnormality begins in March, attains the maxim
in June, and terminates in October. It is thus confi
to the warmer months of the year, and, unlike m
meteorological phenomena, is not cumulative, but foll
the sun, so that its maximum occurs in June, and no
July as that of the temperature of the air, or in Augus

perature of the sea. The smallness of this range e North Atlantic, which is less than occurs in any ocean in the same latitudes, is to a large extent by the small dip in the diurnal curve of the after- inimum.

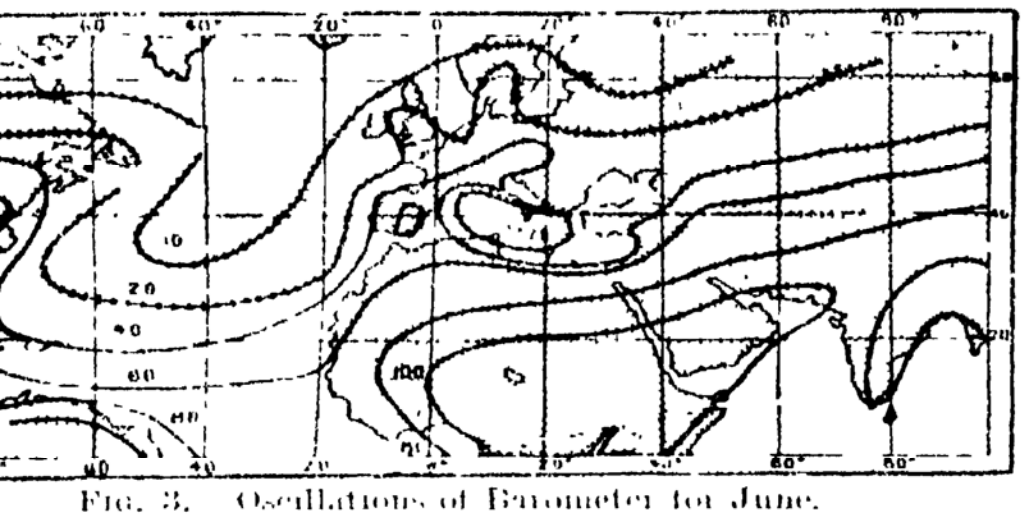

FIG. 3. Oscillations of Barometer for June.

e map of the distribution of pressure over the globe y be examined (fig. 17) it is seen that this part of ntre is occupied by a well defined area of high ressure, higher indeed than occurs at any season y ocean; and it is shown below that out of this e surface winds blow in all directions. But, since constantly being drained out of this region by d without diminishing the pressure, it follows of y that the high pressure must be maintained by ns of air received from above through the upper s. Now the regions whence such accessions can e the upper currents which have their origin in the ng currents that rise from the heated plains of Africa, the belt of calms, and the two Americas sur- g the North Atlantic. It is evident that the major of each day's overflow of air from the continents the upper regions of the air upon the Atlantic. r this overflow takes place by convection currents or tidal movement similar to what has been already d, will take place during mid afternoon. In other the overflow will occur about the time of the after- inimum of the Atlantic, thus diminishing the dip of nimum, and so producing the abnormally small range der examination. It is in favour of this view that ormality follows the sun's course and is not cumula- d is felt also on both sides of the Atlantic, even h the weather on the east side is dry and all but , and on the west moderately moist and characterized ther copious rainfall. It is also full of significance e peculiarity is most strikingly seen in that part ocean of the globe which is closely hemmed in by sses of land.

nce of the Moon on Atmospheric Pressure. Fifteen nonthly observations have been made at Batavia and ed by the late Dr Bergsma in their relation to the ay, which was assumed in the calculations to com with the time of the upper transit of the moon. The f the inquiry is that atmospheric pressure at Batavia nar tide quite a distinctly marked as the ordinary barometric tide, except that its amplitude is much The four phases are these:—

1st max.	0·0062 inch	at lunar hour	1
1st min.	−0·0021	,, ,,	7
2d max.	+0·0025	,, ,,	13
2d min.	−0·0024	,, ,,	19

nar tide has the important difference that its phases the moon's apparent course much more closely than inary diurnal fluctuations of the barometer follow the sun. The two maxima occur about the 1st and nd the two minima about the 7th and 19th, whereas our daily phases of the diurnal barometric fluctua- ur with respect to the sun's apparent course from one to six hours later. It is interesting to note that higher latitudes in inland situations during winter times and in situations where the disturbing influe temperature and humidity tend towards a minimu times of occurrence of the four phases of the daily tion of the barometer approximate to those of the lunar atmospheric tide.

Since a distinct lunar tide is traced to the att influence of the moon, it follows that the att influence of the sun will enter as one of the several which determine the phases and amplitude of the barometric curve. It also follows from the muc attractive influence of the sun than that of the m the earth's atmosphere that the effects of the sun's tion on the pressure will be wholly concealed by the larger effects of the other forces concerned in deter the diurnal oscillation, except in the case or cases the variation in the fluctuation is small at 1 and and 1 and 7 P.M. Now at places north of lat. 45° variation at 1 A.M. is small during the winter, and singular fact that some years ago Rykatchew Petersburg drew the attention of meteorologists existence at these northern stations of a faintly third maximum; and it is further of importance to that, at many places where on the mean of years th maximum is scarcely or not at all marked, it app the mean of some of the separate years. Thus, the does not appear in the mean of the twenty years 1873 at Greenwich for January, it appears in nine individual years. It is highly probable that this mum, which may be named Rykatchew's maximu its discoverer, is due to the attractive influence of t its amplitude and time of occurrence being in acc with such a supposition.

Diurnal Variation of the Force of the Wind.— the three and a half years' cruise of the "Chall ending with May 1876, observations of the for direction of the wind were made on 1202 days, a

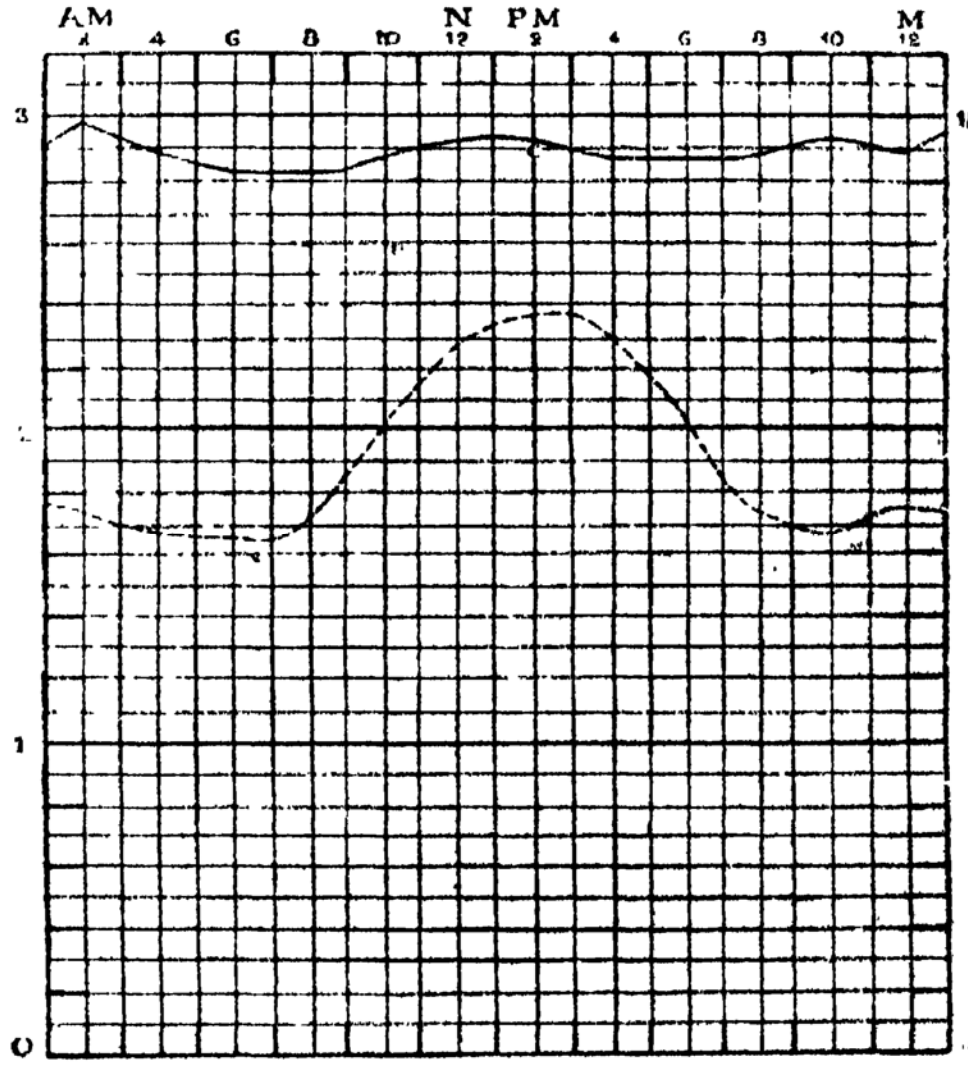

FIG. 4.—Diurnal Force of Wind at Sea and near Lan

twelve times each day,—650 of the days being on t sea and 552 near land. The observations of for made on Beaufort's scale 0–12, being the scale o force observed at sea. The mean diurnal force wind on the open sea and near land respectively is

, where the figures on the left are Beaufort's scale, se on the right the equivalents in miles per hour. olid line shows at the different hours of the day an force on the open sea, and the dotted line the orce near land.

egards the open sea it is seen that the diurnal on is exceedingly small, there being two apparent maxima, about midday and midnight respectively. mining, however, the separate means for the North outh Atlantic, North and South Pacific, and the rn Ocean, there is no uniform agreement observable their curves, the slight variations which are met eing different in each case. It follows therefore e force of the winds on the open sea is subject to inct and uniform diurnal variation. The difference n the hour of least and greatest mean force is less mile per hour.

e different is it, however, with the winds encountered "Challenger" near land, the force of the wind giving a curve as pronouncedly marked as the y diurnal curve of temperature. The minimum a at 2 to 4 A.M. and the maximum from noon to 4 he absolute highest being at 2 P.M. The curves cted for each of the five oceans from the observa ear land give one and the same result, or a curve accordant with the curve of diurnal temperature. fferences between the hours of least and greatest re as follows:—Southern Ocean 6½ miles, South 4½ miles, South Atlantic 3¼ miles, and North c and North Pacific 3 miles per hour

he case of each ocean the velocity of the wind on en sea is considerably in excess of that near land, no case does the maximum velocity near land, ch about midday, reach the velocity of the wind on n sea. The 650 daily observations on the open sea mean hourly velocity of 17½ miles, whereas the 552 nd give a velocity of only 12½ miles per hour. The nce is greatest at 4 A.M., when it amounts to upwards iles an hour, but is diminished by the rising tem re till at 2 P.M. it is less than 3 miles an hour.

auritius, which is situated within the south-east trades, the n velocity of the wind is 9·7 miles per hour, occurring from .M., from which it rises to the maximum 18·5 miles from M., the influence of the sun being thus to double the wind's . At Batavia, situated in a region where the mean baro- gradient is much smaller, the differences are still more de- From 1 to 6 A.M. 85 per cent. of the whole of the obser are calms, whereas from noon to 2 P.M. only 1 per cent. ns. In all months, the minimum velocity occurs in the orning, when the temperature is lowest, and the maximum to 3 P.M., when the temperature is highest, the mean m and maximum velocities being to each other as 1 to 21. mbra the mean maximum hourly velocity is five times than the minimum hourly velocity in summer, whereas in it is only about a half more. At Valentia, in the south- Ireland, one of the windiest situations in western Europe, e summer months of 1878 gave a mean hourly velocity of les per hour, the minimum oscillating from 10 to 11 miles from 9 P.M. to 6 A.M., and the maximum exceeding 16 hour from 11 A.M. to 5 P.M. The absolute lowest hourly as 10 miles at 11 P.M., and the highest 18 miles at 1 P.M., ocity about midday being thus nearly double that of the Many observations might be added to these, including ublished by Hann, Koppen, Hand , and others, which go lish the fact that the curves of the diurnal variation of the of the wind generally conform to the diurnal curves of ture. The curves are most strongly marked during the months; and the maximum velocity occurs at 1 P.M. or thereafter, being thus before the time of occurrence of the m temperature of the day, and the minimum in the early g, or about the time when the temperature falls to the The rule also holds good with all winds, whatever be their n. The exceptions to this rule are so few and of such at they are probably to attributed to causes more or local character.

has shown, for a number of places in northern Europe, that clear sky the velocity is doubled from the minimum the maximum, with a sky half covered the velocity is three greater, and with a sky wholly covered the velocity is only more. On the other hand at the strictly inland situation of with a clear sky the velocity is double, and with a sky half it is two-thirds greater, but with a covered sky the diurnal tion in the wind's velocity becomes irregular and faintly Hann has also examined the winds at Vienna, and found that of a velocity not exceeding 30 kilometres an hour show diurnal increase from 11 kilometres at 6 A.M. to 16·8 at 1 that winds of velocity exceeding 30 kilometres an hour exhibit a faintly marked and irregular increase of velocity during the

In offering an explanation of this remarkable fact ing the diurnal variation in the velocity of the wind climates, it is to be remarked that the minimum occurs when terrestrial radiation and its effects are g but the increase of the velocity closely follows the and the maximum is reached nearer the time t crosses the meridian than perhaps any of the other t or minima of meteorology which are dependent sun's diurnal course. It is also to be noted that the over the open are practically uninfluenced by and terrestrial radiation, for there the diurnal cu variation in the force of the wind is all but a straight On nearing land, however, the wind's force exhi diurnal curve of variation as distinctly marked a bearing a close resemblance to the analogous cu temperature; while on the land itself these f become still more decidedly pronounced. Last amount of the diurnal variation of the temperature surface of the sea is less than a degree, whereas o land surfaces the diurnal variation of the tempera large, even where the ground is covered by vegetatio enormously large over sandy wastes.

From this it follows that, so far as concerns any influence on the air itself, solar and terrestrial ra exercise no influence on the diurnal increase of the v of the air with the increase of its temperature, or, influence at all, such influence must be altogether unificant, as is conclusively shown by the wind obser of the "Challenger" over each of the five great oc the globe. The same observations show that on land the wind is everywhere greatly reduced in The retardation is greatest during the hours when th temperature is at the minimum; and it is particu be noted that, though the temperature rises consid no marked increase in the velocity sets in till about when the temperature has begun to rise above the mean. From this time the increase is rapid (see the maximum is reached shortly after the period of st insolation; and the velocity falls a little (but only a during the next three to five hours, according to latitude, and position, and falls again to near the mi shortly after the hour when the temperature is mean. Even at the maximum, the velocity nea falls considerably short of the velocity which is maintained over the open sea by night as well as by

The period of the day when the wind's velocity creased is practically limited to the hours when the te ture is above the daily mean, and the influence higher temperature is to counteract to some extent tardation of the wind's velocity resulting from friction from the viscosity of the air. The increase in the velocity of the wind is in all probability due to the heating of the surface of the ground and to the con ascensional movement of the air, tending to counte effect of friction and of viscosity between the low stratum of the air and the ground. It is of imp in this connexion to keep in view the fact that in weather a temperature much higher than might ha supposed is often radiated from the clouds down u earth's surface,[1] which accounts for the phenomenon

[1] *Journal of Scottish Meteorological Society*, vol. ii. p. 2

variation in the wind's velocity occurring frequently
cloudy weather. On the other hand, during the
when terrestrial radiation is proceeding, the tempera-
the surface falls greatly, and instead of an
onal movement in the lower stratum of the air there
er a tendency towards a descen-tional movement (if
nd be light there is an actual movement) of the
air stratum down the slopes of the country; and
he friction between the wind and the surface of
th is thereby increased the diurnal velocity of the
falls to the minimum during these hours (see also
).

ong the most marked exceptions to the general rule
diurnal distribution of wind force may be cited the
y cold furious blast of wind encountered in narrow
in such mountainous regions as the Alps during
nd comparatively calm nights. These are simply
rush of the cold air poured into the upper basins
valleys by the descensional currents from the slopes
the chilling effects of terrestrial radiation set in

On the other hand, the air of the valleys becomes
and expands during the day, thus giving rise to a
wind blowing up the valleys, which, on account of
som it carries with it from the lower level, fre
covers the higher slopes and tops of the mountains
oud and drizzling rain

nal Variation in the Direction of the Wind. In all
near seas and other large sheets of water, where
ribution of atmospheric pressure is tolerably equable,
barometric gradient small, and the sun heat
tely strong, land and sea breezes are of daily
nce. In such places a breeze from the sea gradually
in the morning, which gradually rises to a stiff
during the heat of the day and again toward-
sinks to a calm. Soon after this a breeze sets in
land, blows strongly seaward during the night,
s away in the morning, giving place to the sea
as before. These breezes are occasioned by the
of the land being heated in a much higher degree
at of the sea during the day; the air over the land
thereby made lighter ascends, and its place is
d by the cooler air of the sea breeze drawn land
nd partly also by descending currents, as shown
humidity observations of the "Challenger," which
e increasing dryness when the sea breeze is strongest.
during the night the temperature of the land and
air over it falls below that of the sea, and the air of
d thus becoming heavier and denser flows over the
a land breeze. As the best marked and most fre
occurring cases of the sea breeze begin some
out at sea and gradually approach the land, it is
robable that, as suggested by Blanford, the ascend
ated air flows seaward as an upper current, and that
creased barometric gradient thus caused largely
ts for the e breezes.

nd land breezes are thus determined by the relative posi-
the land and its coasts subject to a further modification
from the rotation of the earth. Thus on the coast of the
f Lyons the sea breeze from the south veers to south-west
s away as a west wind, while the land breeze from the north
ly veers to north-east and dies away as an east wind. On
st of Algeria, on the other hand, the sea breeze veers from
o north-east and dies away in the east, whereas the south
reeze veers to south-west and dies away in the west. Sea
also occur in such unsettled climates as that of Scotland,
e weather conditions are favourable. These conditions are
d when an anticyclone overspreads the country, with its
nying fine settled weather, small variation in the distri-
of atmospheric pressure, clear skies, and consequently strong
. Under these conditions the following are the veerings of
d off the coast of Berwickshire. In the morning the wind is
st till about 10 A.M., when it veers to north, falling all the
finally it sinks to a calm. A little before noon it springs up
from north-east or east, veers to south-east from 2 to 3 P.M.
it continues till 7 P.M., about which time it veers to south-wa
south-west, diminishing in force and finally sinking to a calm.
sunset it springs up from west, veering to north-west dur
night, where it continues till the following morning. The wi
virtually makes the round of the compass, is strongest from
west and south-east and weakest at north-east and south-wes
thus strongest when its course is perpendicular to the line o

The observations made by the "Challenger" in the regio
north-east trade in 1873 show a small diurnal variation
direction of the wind, the variation being from E. 47° S.
to 6 A.M. to E. 56° N. at 10 A.M. to 2 P.M., the variatio
thus 8° 55' towards north during the hottest hours of the d
Mauritius observatory, which is several miles from the
daily period in the direction of the wind is from E. 22°
at 4 A.M., being the most southerly point, to E. 7° S. at
and thence back to E. 22° 15' S. at 4 A.M. The diurna
tion is 15° 15', and thus the influence of the sun impresse
wind at this observatory a more truly easterly character.

At the Austrian naval station at Pola, near the head
Adriatic, the daily variation in the direction of the wind
marked. Starting from a point east of south at 5 A.M., it g
veers round to westward, the most westerly point, almost d
being reached at 5 to 6 P.M., after which it gradually shifts
its starting point in the morning. Here we have evidently a
wind system different from that of the land and the sea
Pola is situated near the south-western extremity of the pe
of Istria, and the direction in the early morning of east by
the direction the wind would take if a small anticyclone ov
the peninsula, and the direction from the west in mid af
is the direction the wind would have at Pola if the peninsu
occupied by a small cyclone with the lowest pressure in the
Now the influence of solar radiation is to form, throu
ascending current from the heated land, a diminution of
over the land, in other words, what is essentially a cyclo
the other hand, during the night the influence of terrestri
tion is to generate, through the cooling of the land and
resting above it, a relatively higher atmospheric pressure
interior of the peninsula with its characteristic system
blowing winds.

At Coimbra, in July 1878, the diurnal variation of the win
tion was from W. 49° 37' N. at 2 to 6 A.M. to W. 35°
at 4 to 6 P.M., the amount of the variation being thus 16° 2
direction of west. At Valentia, in the south-west of Ireland
the summer months of 1878 the diurnal variation of the
direction was from W. by S. at 7 to 9 A.M. to S.
W. at 5 to 7 P.M. The variation was thus from a poin
south to a point nearly south-west, or through nea
in the direction of west. On the other hand, at A
during the same months of 1878, the diurnal variation
wind's direction was from S.W. at 6 to 7 A.M. to S. by E
to 4 P.M. the variation being thus 56° from south-west
direction of east through south. "Attention is here draw
exactly opposite ways in which the diurnal veering or shi
the wind takes places at Valentia and Aberdeen, but partic
the important circumstance that in each case the diurnal
in the wind's direction which actually occur are precisely th
would take place on the supposition that during the hotte
of the day an ascensional movement of the air sets in f
heated lands of the British Islands, and that an in-draug
place all round, which with the descending currents mak
the loss caused by the up-draught. Thus then both the
increase in the wind's velocity and the change in its
which observation shows to take place during the hottest
the day are traced to the same cause, viz., the heating
surface by the sun, the heating of the lowest stratum of ai
on the surface, and the ascensional movements which are th
sary result.

It is instructive to note that at Nukuss, at some distanc
south of the Sea of Aral, where the summer direction of the
northerly, the north component is at the daily maximum a
having shifted into this direction from north-east, where
9 A.M. Much or nearly everything remains to be done in
out this problem in its practical details as one of the in
elements of climatology, with the view of arriving at some
knowledge of the influence of physical configuration and
vegetable coverings of the surface on radiation and on the
and direction of the wind.

Diurnal Variation in the Amount of Cloud. Mi
fogs are visible vapours floating in the air near the
of the earth, and clouds are visible vapours at a co
able height. These forms of visible vapour are all pr
by whatever lowers the temperature of the air bel
dew point,—such as radiation from the molecules
atmosphere towards the cold regions of space, the

on of the air of ascending currents, the mixing of with air that is warm and moist, and the cooling air in contact with the surface of the earth when its ature has been lowered by nocturnal radiation.

forms of clouds are endless. Since clouds are to certain distinct modifications from the same which produce other atmospheric phenomena, the the sky may be regarded as indicating the operation causes, just as the face of man indicates his mental ysical states. Hence the importance of the study ds, and hence the necessity of a nomenclature of as the basis of accurate and comparable observations. equate nomenclature of clouds is still a desideratum. Howard's classification, which continues to hold its as a provisional nomenclature, was proposed by 1803, and by it clouds are considered as divided ven kinds. Of these, three are simple forms, the the *cumulus*, and the *stratus*; and four intermediate pound, the *cirro-cumulus*, the *cirro-stratus*, the *-stratus*, and the *cumulo-cirro-stratus*, *nimbus*, or *rain*

cirrus cloud consists of wavy, parallel, or divergent ts, which may increase in any or all directions. It loud of the least density, the greatest elevation, and eatest variety of figure. It is probable that the s composing it are minute crystals of ice or snow The cirrus is intimately connected with the great ents of the atmosphere; and it is solely from the ents of the cirrus that we have any direct know- f the upper currents of the atmo-phere. In recent much has been done, particularly by Professor randsson of Upsala and Clement Ley, in investi- the relations of this cloud to storms and other s of weather.

cumulus is the name applied to those convex or heaps of clouds which increase upwards from a tal base. They are generally of a very dense re, are formed in the lower regions of the atmo- and are carried along by the aerial current next th. They form the tops of the ascending currents rise from the heated ground, and have a diurnal so well marked that they are often named the of the day." The form of stratus comprehends nists and fogs which in the calm evening of a warm r day make their appearance in the bottom of valleys er low-lying grounds, and sometimes spread upwards e surrounding country like an inundation; they n equally well marked daily period, and are ntly called the "cloud of night." The cirro- us is made up of small roundish masses, lying near ther, and quite separated by intervals of sky. It considered as formed from the cirrus by the fibres cloud breaking, as it were, and collapsing into sh masses, thus destroying the texture but retaining angement of that cloud. This singularly beautiful is commonly known as a mackerel sky, and is of equent occurrence during dry warm summer weather. rro-stratus consists of horizontal masses thinned s the circumference, bent downwards or undulat- d either separate or in groups. Since this cloud eat extent and continuity of substance, but little dicular depth or thickness, it is the cloud which requently fulfils the conditions for the phenomena ona, solar and lunar halos, parhelia or mock suns, araselenæ or mock moons. The cumulo-stratus ed by the cirro-stratus blending with the cumulus, eading underneath it as a horizontal layer of vapour. umulo-cirro-stratus, or nimbus, is the well known oud, which consists of a cloud or system of clouds which rain is falling. At a considerable height a sheet of cirro-stratus cloud is extended, under cumulus clouds drift from windward; these rapi creasing unite and appear to form one continuo mass from which the rain falls. The breaking up lower grey mass indicates that the rain will soo When a rain cloud is seen at a distance, cirri ap shoot out from its top in all directions; and it is o that the more copious the rainfall the greater is play of cirri. The cirrus, cirro-cumulus, cirro- cumulo-stratus, and nimbus are connected more closely with the great atmospheric movements cyclone and anticyclone. In what follows here amount of sky covered will be taken into account, the species of cloud covering.

The diurnal variation in the amount of cloud in on the open sea is very small. The following are the of two hundred and seventy-seven days' observat board the "Challenger," stated in percentages covered:—

2 A.M.	59	10 A.M.	58	6 P.M.	
4 ,,	59	Noon	56	8 ,,	
6 ,,	62	2 P.M.	58	10 ,,	
8 ,,	62	4 ,,	59	Midnight	

Two maxima are here indicated, the one about or after sunrise and the other in the early part afternoon, and two minima, the one at noon and th from sunset to midnight. The difference betwe extremes is only 6 per cent. of the sky.

At Batavia the daily maximum is from 6 to 11 P.M., minimum from 8 to 11 A.M., the extremes being 73 per 9 A.M. and 69 per cent. at 7 P.M.—a difference of 17 per c four daily observations at Mauritius, the maximum is 50 p at 1 P.M. and the minimum 38 per cent. at 6 A.M. At C observations of clouds have been made five times daily, years' results give the maximum 63 per cent. at 9 P.M minimum 52 per cent. at 9 A.M. At this place, during August, the greatest amount of cloud occurs at 6 P.M., and months the rainfall at Coimbatore is very small. The minim more pronounced at 9 A.M. than at any other period in this phase occurs about four hours later. At the con-stantinople of Vienna, during the warm months of the year th mum is at 2 P.M., with a secondary maximum about 6 A the minimum from 10 P.M. to 2 A.M.; but during the cold the maximum is at 6 A.M. and the minimum during the and night. In the Rocky Mountains, the chief maximum cent., is at 3 P.M., with a secondary one 30 per cent. at 5 A the chief minimum 20 at 3 A.M. and a secondary one 24 at A.M. At Helsingfors the maximum of cloud occurs from 10 A.M. to and the minimum from 10 P.M. to 2 A.M.

Much yet remains to be done with regard determination of the diurnal variation of cloud, bu the above one or two deductions of a general ch may be drawn. A maximum occurs in the morn continues till shortly after the sun has risen, a maximum is more decidedly pronounced over the o than over land. Its appearance is without a doubt the general cooling of the atmosphere through its height by terrestrial radiation, and its disappearan the heating of the air, which commences about Then follows one of the diurnal minima, which co till midday, or a little later; in other words, it co till, owing to the diurnal heating of the air by t the ascending current has fairly set in. The pe this ascending current marks the second maximum during the warmer months is larger than the maximum over land. The cumulus is the chara cloud of this maximum. These clouds are mer summits of the ascending currents which rise fr heated land, where the aqueous vapour i condens cloud by the expansion which takes place with inc height.

These cumulus clouds throw a not unimportant l the behaviour of the ascending currents which ri the surface when heated by the sun,—inasmuch

to the fact that the current ascending from the
e is broken up and thereafter grouped into separate
defined ascending currents, which are marked out and
pped by these cumuli; and further it is probable,
their well-defined position, that the air composing
ascending currents is not only warmer but also more
d than the air in the clear interspaces at the same
ts. It may also be regarded as highly probable that
lown through these clear interspaces that the descend-
ir filaments shape their course on their way to take
lace of the air-molecules that ascend from the heated
ce of the earth.

e secondary minimum occurs from about sunset
rds during the time of the P.M. maximum of atmo-
ric pressure. In a highly saturated atmosphere, which
characteristic a feature of many tropical climates at
n seasons, the time of the day is remarkable for the
unt of cloud, and it is during those seasons and hours
heat-lightning, or lightning without thunder, attains
nual and diurnal maximum period, which is from six
ght hours later than that of thunderstorms. The
ng maximum, shortly before and after sunrise, has
quite distinct and characteristic clouds accompanying
One of these is the cumulo-stratus, which is a con
nce of the cooling of the atmosphere through all its
t by nocturnal radiation. As the colouring of the
llets is often singularly fine, it has been a favourite
e with poets of all ages and climes. The other, which
ts from the cooling of the surface of the earth by
strial radiation and thence of the lower stratum of
atmosphere, is quite different, being a low creeping
appearing first in low-lying situations, and gradually
nding upwards as the temperature falls. Fog is a
known form of this cloud, having its diurnal maximum
e morning and early part of the day.

urnal Variation in the Amount of the Rainfall.
the sixteen years during which hourly observations
e rainfall were made at Batavia Dr Bergsma has given
le showing the diurnal variation, of which the follow-
shows how much per cent. of the total daily amount
very two hours

to 2 A.M.	8·7	8 A.M. to 10 A.M.	9·5	4 P.M. to 6 P.M.	13·5
,, 4 ,,	6·4	10 ,, ,, Noon	6·3	6 ,, ,, 8 ,,	10·5
,, 6 ,,	6·1	Noon ,, 2 P.M.	9·3	8 ,, ,, 10 ,,	7·1
,, 8 ,,	9·2	2 P.M. ,, 4 ,,	12·2	10 ,, ,, Midt.	8·7

diurnal curve of rainfall is thus very distinctly
ed at Batavia. The minimum is from 6 to 10 A.M.
the maximum from 2 to 6 P.M.,—10·7 per cent. falling
the four hours ending 10 A.M., but 25·7 per cent.
e four hours ending 6 P.M.

observations were arranged and averaged by Dr Bergsma
the view of seeing how far the phases of the moon influence
rainfall. The results for the eight phases of the moon,
ming with new moon, showing the mean amount of rain in
ty-four hours during the seventeen years ending 1880, are
: 0·213, 0·195, 0·193, 0·181, 0·212, 0·183, 0·189, and 0·203,
daily mean 0·205 inch. The influence of the moon's phases
e rainfall at Batavia is thus quite decided from these seventeen
s, for, while the mean daily rainfall is 0·205 inch, it rises at
noon to 0·213 inch, from which time it gradually falls to
inch at the third octant, rises to 0·212 inch at the fourth
nt, falls again to 0·183 inch at the fifth octant, and finally
to the maximum at the time of new moon.

Coimbra, where the rainfall has been observed every two
s for the six years ending 1881, the means show a minimum
08 inches from midnight to 2 A.M., a maximum of 4·03 inches
2 to 4 A.M., a second minimum of 3·20 inches from 10 A.M.
oon, and a second maximum from 2 to 4 P.M. These four
es of the rainfall are pretty nearly accordant with the four
es of the barometric pressure, the maximum periods being
the times of minimum pressure, and the minimum periods
the times of maximum pressure. The rainfall at Philadelphia
s a decided maximum at 6 P.M. and minimum at 3 A.M. At
na during the summer half of the year there are three maxima
three minima in the curve of the daily rainfall, the chief

maximum, which is nearly double of each of the othe
occurring from 2 to 4 P.M., and the chief minimum from
A.M. At this place the number of hours of rain has been re
showing two maximum periods, the first from 2 to 8 A.M.
second from 4 to 7 P.M. Since the time of maximum
indicates a number of hours for the fall under the mean of t
it follows that the showers from 2 to 4 P.M. are often very
At Prague the chief maximum is from 2 to 6 P.M. and the m
from 1 to 6 A.M. At Zechen the maximum is from 2 to
with a secondary maximum from 5 to 8 A.M., and the m
from midnight to 4 A.M. At Bern the maximum fall is from
to midnight. Twenty one years' observations at Calcutt
the maximum occurrence of rainfall during the rainy seas
June to October to be from 11 A.M. to 6 P.M., the absolute ma
being from 2 to 3 P.M. and the minimum from 9 P.M. to
and during the hot dry season from March to May the maxi
from 5 to 9 P.M., and the minimum from midnight to 9 A.M.

The data already collected show the general occu
of a diurnal maximum from about 11 A.M. to 6 P.M
this feature of the curve is particularly well seen
rainfall of continental climates during the summer
the year. A marked diminution of the rainfall i
generally observed from about sunset to midnight
the diurnal amount of cloud in many climates falls
minimum, and the evening maximum of atmo
pressure takes place. The time of the morning mi
pressure from about 2 to 6 A.M. is, curiously, s
marked in some places with an increase, while in ot
is as strongly marked with a diminution, in the r
The "Challenger" observations show that the occ
of rain on the open sea is inversely as the tempe
684 days' observations giving 96 cases from 9 to
and 135 from midnight to 2 A.M., these being the mi
and maximum periods.

Diurnal Variation of Thunderstorms. It has ju
remarked that a prominent feature of the diurnal
in continental climates during the summer month
increased rainfall from about 11 A.M. to 6 P.M., a
Vienna observations point to unusually heavy falls
ring at these hours. This is caused by the rains
accompany the thunderstorms of these regions.
following table gives for the hours of the day the t
occurrence of thunderstorms at Ekaterinburg in th
Mountains during the fourteen years ending 1872:

Hence the thunderstorms at this place have a
period as strongly marked as any other meteor
phenomena, and in this respect Ekaterinburg i
representative of extratropical continental climates
summer. For the fourteen years no thunder

the six months from October to March. The mean six hottest months shows the maximum to take om 3 to 4 P.M. and the minimum from 4 to 5 A.M., oing the times of occurrence of the two minima of e. At this season, however, the morning minimum e is but faintly marked in such climates as those of During the twelve hours from 9 A.M. to 9 P.M., ne temperature is above the daily mean, 717 of the number occurred, thus leaving only 139 for the hours when the temperature is below the daily The great majority of the thunderstorms occur the part of the day when the ascensional movement air from the heated ground takes place, and they the maximum when the temperature and this movement are also at the maximum. Owing to sterly winds from the Atlantic which prevail over and western Siberia during summer, the maximum of the year occurs over this extensive region in this and the importance and significance of the inquiry s element of climate lie in the fact that the greater of the summer rains is discharged over these regions thunderstorm. The "Challenger" observations on n sea show the maximum occurrence of thunder to be from 10 P.M. to 8 A.M., 22 being observed these ten hours and 10 during the other fourteen f the day,—a result which suggests that over the terrestrial radiation is more powerful than solar on in causing vertical disturbances in the equilibrium atmosphere.

ospheric vapour and ascending currents thus play ortant part in the history of these thunderstorms. the climate is dry and rainless, like that of Jerusalem ner, thunder is altogether unknown. On the other where during a particular season an anticyclone with descending current in the centre remains over a as happens over the centre of the old continent the winter, over that region thunder is equally n during that season. Further, in such places as and Coimbra, where the summer rainfall is small occurrence infrequent, thunderstorms become less t, and the hours of their occurrence are later in the an they are before and after the dry season.

hunderstorms at Mauritius call for special notice. There maxima in the diurnal curve, the larger from noon to 4 l the smaller from 3 to 6 A.M., which are near the times of ometric minima, and two minima, from 9 P.M. to 1 A.M. n 8 to 10 A.M., these being near the times of the barometric . But the important point as regards the thunderstorms itius is that for twelve years none were recorded in June y, one only in August, one in September, and three in The annual period of the thunderstorms of this island from near the end of October to the middle of May, or he time of the greatest rainfall, practically none occurring the rest of the year. But rain continues to fall during r months of no thunder, the mean monthly rainfall being out 2 inches, falling, however, in September to 1·37 During these four months, therefore, there is in the air eous vapour, and, these being dry months, there is the n of ascending currents. There appears, however, to n wanting another element which seems essential to trical manifestations of the thunderstorm, viz., the con- which give masses of descending cold air along with ending current of warm moist air. During the months hunder is of no unusual occurrence the high pressure of Asia lly advances, as Dr Meldrum has pointed out, close on us; and so frequently is this the case that he considers the calms between the two trade winds to stretch in a slanting n from Madagascar to Ceylon. As long as this state of occurs with more or less frequency, the conditions of a ing cold current of large volume are provided, and thunder- occur. But during June, July, August, and September, tmospheric pressure is low in Central Asia, and there is an on increase of pressure from Asia southwards to Mauritius, ile Mauritius remains in the heart of the south-east trades, nditions of descending cold currents of any considerable are not present, and thunder is there unknown at that

Now in situations which afford the three conditions of a vapour, ascending currents, and descending cold currents, the diurnal and annual periods are quite distinctly marked phenomena are more uniformly distributed through the hour day and months of the year than elsewhere. Pola and Fiu the head of the Adriatic, being shut in and encompassed b Alps, are illustrations. At Fiume the greater maximum from 11 A.M. to 1 P.M. and the smaller from 2 to 4 A.M., minima from 10 P.M. to 1 A.M. and 6 to 9 A.M. While dur twelve hours the temperature is above the mean of the da May to September the number of the thunderstorms here for the nine years ending 1879, the number during the hours the temperature is under the mean was 185. The tively large number during the colder hours of the night is due to the warm moist atmosphere of this confined sea close proximity of the Alps.

There is still another set of conditions favourable of thunderstorms in certain climates which the obser made at Stykkisholm in the north-west of Iceland ill During the four and a half years ending 1879 there occurred here three thunderstorms, but there was only one in the six months from April to September, in other words, the t storm of the climate are essentially winter phenomena. I of the twenty-three hours in which they occurred, only thr at a time of the day when the sun was above the horizo twice in March and one in September: in other words, the t storms of Stykkisholm are nocturnal phenomena. It is most ob the north and north-west of Scotland t occurs most frequently during the day and in summer the thunderstorms in the are approximative in type to those of Iceland and in the to those of Edgeworthstown. A little reflexion shows that in western Europe it is during winter and during night that moist ascending and cold dry descending currents are mo quently brought into close proximity during the great storms of the season, and it is at the changes of wind, hu and temperature accompanying the passage of the centre cyclones that the thunder peals are heard. On the other in the east and south of Scotland it is during the hot of the year that these ascending columns of warm moist descending columns of cold dry air are most frequently together, and there, accordingly, thunder with the heavy which accompany it is of most frequent occurrence from to 5 P.M. from May to September. These essentially differen of thunder-storms have been classed by Mohn as heat thunde and cyclone thunder-storms.

Given an initial difference of electric potential, it to understand from the effects which follow the extraordinary condensations of the aqueous vapour take place how the most violent thunder-storms a duced. The difficulty is to account for the produc the initial difference of electric potential, ho example, in the same great aerial current of the sou monsoon, this difference of potential is produced molecules of aqueous vapour at Calcutta but not aqueous vapour at Mauritius. It is to the physici meteorologist still look for the explanation.

Diurnal Period in the Occurrence of the Whi Waterspout, Dust Storm, and Tornado. Whir waterspouts, dust storms, and tornadoes are essentia ame, differing from each other only in their dime their intensity, or the degree in which the moisture densed into visible vapour, while the hailstorm a rainstorm are simply the manner and degree of t cipitation accompanying them. In several im respects they differ widely and radically from cyclon Atmosphere, vol. iii. p. 33). The largest tornad of so decidedly smaller dimensions when compare the smallest cyclones as to admit of no shading of into the other. Cyclones occur at all hours of t and night, whereas whirlwinds and tornadoes diurnal period as distinctly marked as any in mete Finally, cyclones take place under conditions which unequal atmospheric pressures or densities at the heights of the atmosphere, due to inequalities geographical distribution of temperature and humidi whirlwinds occur where for the time the air is un warm or moist, and where consequently temperat

ty diminish with height at an abnormally rapid rate. es are thus phenomena resulting from a disturbance equilibrium of the atmosphere considered horizon- ut whirlwinds and tornadoes have their origin in a l disturbance of atmospheric equilibrium

g the most remarkable of the [illegible] portions of the e certain portions of the United States [illegible] to the examina these the meteorological [illegible] of the States has given attention by a systematic [illegible] climate observation attendant phenomena and the destructive effects. The s of the last eighty [illegible] years, numbering about six d, have been classed under [illegible] present State where they rted to have occurred, and [illegible] relative distribu

tion over the States. The areas of greatest frequency are distances from each other. That part of the great bas west of the Mississippi, including the States of Iowa, M Kansas, and Nebraska, is the region in which tornadoes frequent. Tornadoes occur at all seasons, being most f however, from April to September, and least frequent in D and January.

The hour of occurrence of one hundred and sixty-two tornadoes is given in the official report as follows:—

Midt to 2 A.M.	2	8 A.M. to 10 A.M.	1	4 P.M. to 6	
2 A.M. ,, 4 ,,	5	10 ,, ,, Noon	7	6 ,, ,, 8	
4 ,, 6 ,,	3	Noon ,, 2 P.M.	13	8 ,, ,, 10	
6	4	2 P.M. ,, 4 ,,	47	10 ,, ,, M	

Thus the diurnal period of tornadoes is analogous to th

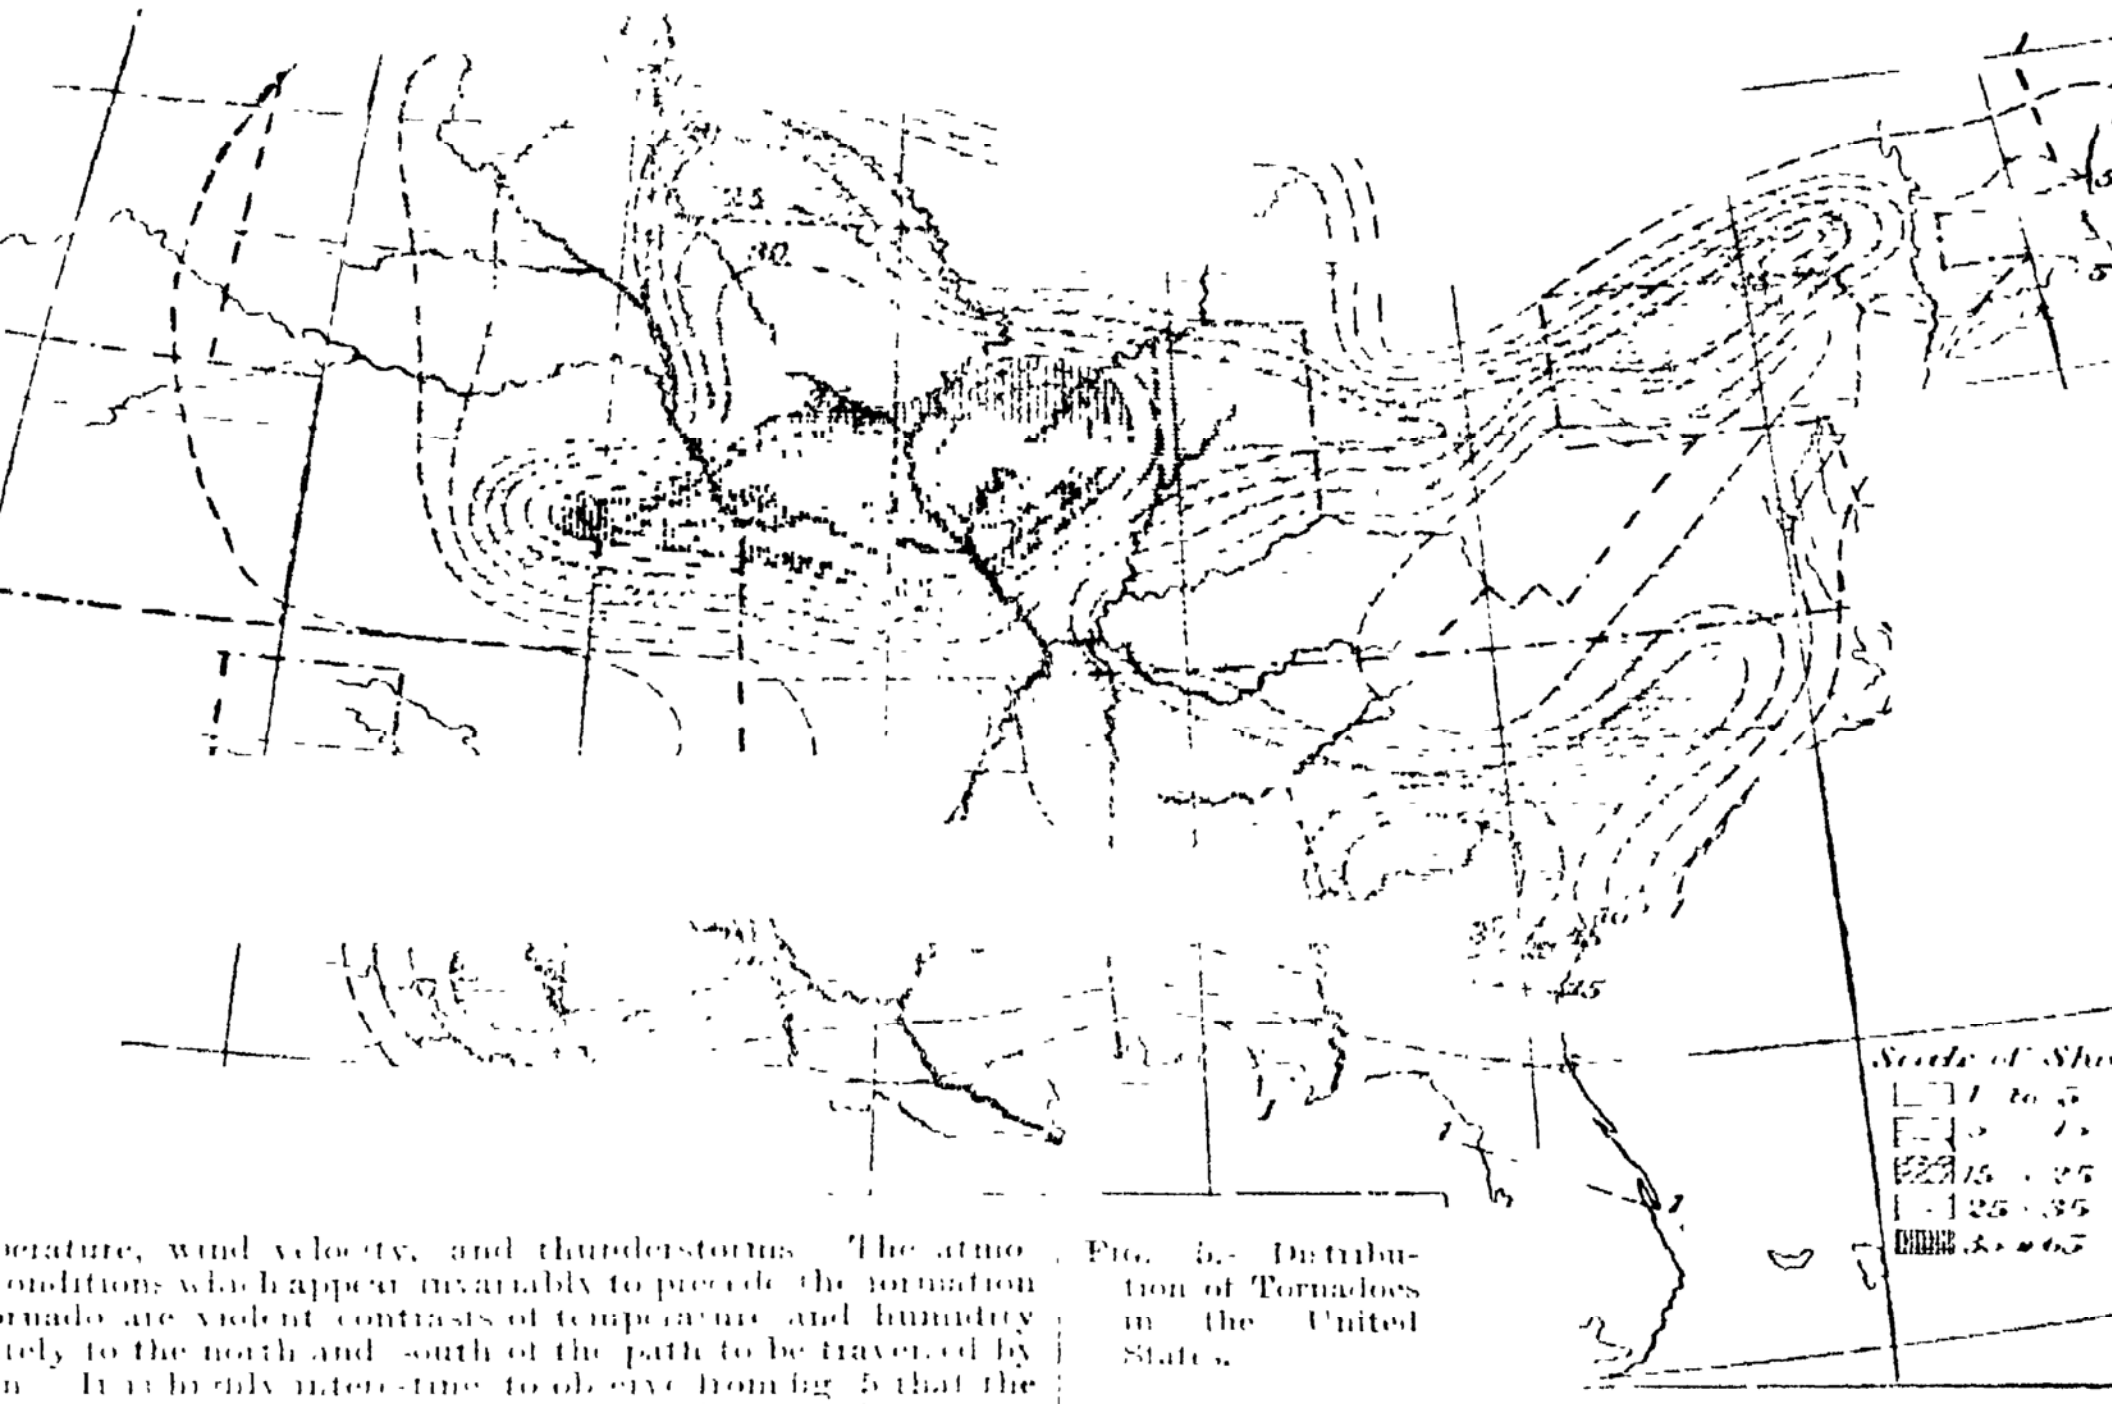

FIG. 5.—Distribution of Tornadoes in the United States.

perature, wind velocity, and thunderstorms. The atmo onditions which appear invariably to precede the formation rnado are violent contrasts of temperature and humidity tely to the north and south of the path to be traversed by n. It is highly interesting to observe from fig. 5 that the t most frequent occurrence of tornadoes is the region large number of the cyclones of the United States appear nate (and the enumeration [illegible] has shown to be remark violent contrast of temperature occurring within limited nd moist, and that as appears in the regions of the ne, they decrease in frequency with height.

6 show the waterspout in different aspects. A loud covers the sky, from which a projection is let n the form of an inverted cone, as at A, which es to increase and extend downwards. The sea iately beneath is soon thrown into violent agitation, g that the whirling movement which began in the has extended to the sea, and is doubtless continuous hout, though the portion of the column from A ards is not yet made apparent by the condensation ontained vapour into cloud. As the whirling move t the column becomes more intensely developed, the d rapidity of the gyrations being increased ion of the air within, with the inevitable result of d condensation of the vapour into cloud downward. otrusion of the cloud and its extension downwards s not due to the descent of vapour from the clouds, he visible condensation of the vapour of the spirally ng air currents arising from an increasing rarefac- e solely to the accelerated rate of the gyrations, the condensation being analogous to that of the cloud exhausting an air pump.

Under each of the columns of fig. 6 the surface ea is seen to be more or less heaped up, as we violent agitation, showing that atmospheric p immediately under the gyrating columns is less th all round. On land, when the tornado passes over a dwelling house or other closed building, i happens that the whole building, walls and roof, is outward with great violence, the wreckage present appearance of a sudden explosion, proving that atmo pressure outside the building was instantaneous largely reduced, and the building shattered to fra by the expansion of the air within. It is in this w the tornado does some of its most dreadful work.

The wind of the tornado reaches a velocity p never equalled in cyclones. During the Ohio tor February 1, 1842, large buildings were lifted enti their foundations, carried several rods through the a then dashed to pieces, some of the fragments being distances of 7 and 8 miles; and large oaks nearly 7 girth were snapped across like reeds. This tornado on its course at the rate of 34 miles an hour, and

id its fearful work in the brief space of a minute nado which passed over Mount Carmel (Illinois), 1877, swept off the spire, vane, and gilded ball of thodist church, and carried it bodily 15 miles to astward. The velocity of the ascending currents kept this heavy object suspended in the air for 15 iles must have been very great

ne tornadoes the progressive courses of which were d, 310 advanced towards N.E., 38 towards S.E., 16 E.N.E., 14 towards E., 7 towards N.N.E., 5 towards and 3 towards S.S.E. The course is thus always

FIG. 6.—Forms of Waterspouts.

some easterly direction, the great majority being the north-east. The velocity of their onward ent varied from 12 to 60 miles an hour, the average 30 miles an hour. The time occupied in passing a lar spot varied from 10 seconds to half an hour, an time being nearly six minutes and a half. The of the path of destruction marked with debris and lies of the violence of the tornado varied from 40 00 feet, the average being 362 yards. The direction whirling movement of the tornado was invariably from left, or the opposite of the movement of the hands atch, resembling in this respect the vortices move f cyclones in the northern hemisphere. The passage tornado cloud is often described as accompanied markable noises, which observers variously charac as terrible, deafening, a terrific crash, the roar of a d trains of cars, or the uproarious din of innumer ces of machinery.

usual position of the gyrating columns of cloud ; but occasionally a curving form or slanting n is assumed. It is probable that to these atter many stationary or slowly moving dangerous squalls be referred, which spring up with unexpected ness in lakes and arms of the sea in mountainous .

dust storm of India, Arabia, and Africa is a well type of the whirlwind. Previous to the outbreak st storm the air is unusually calm and sultry, just ens in the case of the tornado. The simplest form dust storm is that of a tall aerial column of sand onwards, and drawing into itself, as it whirls round ourse, dust and other light bodies within the sweep of the strong air currents which blow along the surf the ground and converge vortices round the bas column. A form commonly seen is shown in no. 7, represents several dust columns grouped toget whirling independently round its own axis with ne air currents at the base, while the whole group of co is borne bodily forward, and presents striking aspe the forms and relative positions of the columns are cha The importance of the observations made on dust s as leading to a correct understanding of the whir consists in this that it affords conclusive evidence there is a strong inflow of air along the surface o ward all round vort towards the base of the wind, and that the air flowing in current after current through the air the central axis of the which, carrying with ther evidence of their ascent, visible solid particles of sand, and other light b they whirl up with the their ascending course.

Owing to the extreme d of the air current mixed the dust storms, the rare generated by the rapidity gyrations is insufficient t duce condensation of the a vapour in the interior column. Quite different, even if with water par tornadoes, where, in the majority of cases, the air the surface before being into the ascending vortex a high temperature and near the point of satu From the extreme rarefaction to which the air-c are subjected, owing to their sudden ascent in a r gyrating column, excessive condensation follows, w aqueous precipitation at times so astonishing that only be fitly described as an aerial torrent of solid water, or an aerial avalanche of hail and ice.

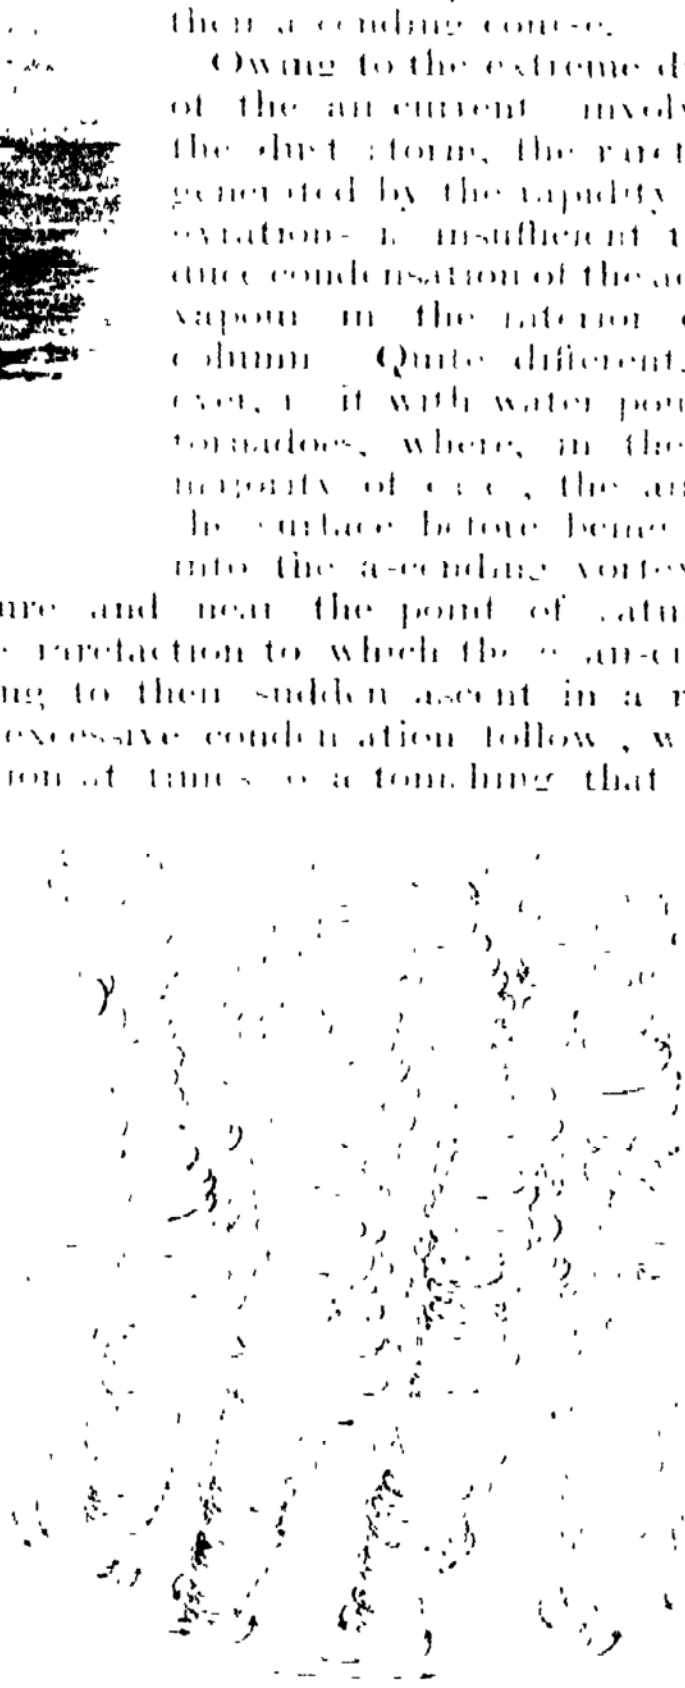

FIG. 7.—Dust-Storm.

Certain tracts of the ocean included within what may be called permanent anticyclones, where atmospheric pressure is higher than all round, are characterized by an absence or comparative absence of rain. These regions are also remarkable for clear skies and strong sun heat. Similarly small anticyclone areas ring between or in the vicinity of cyclone are charact by dry air and clear skies, and it is under these cond that the strongest sun heat is felt. When, as repe

s in the warmer months of the year, anticyclones practically stationary for some time, the lowermost of the air become abnormally heated, thus bringing vertical disturbance of the equilibrium of the atmosont of which whirlwinds originate. It is under these ons that white squalls or fair weather whirlwinds the originating cause of the spiral form being the ryness of the air due to its place in the anticyclone, e abnormally rapid diminution of temperature and ty with height owing to the more or less adiabatic through ar dry atmosphere. The clouds accompanying the squalls are at a great height, but the commotion and of the sea under them and following them as they wards show that the squalls are true whirlwinds, pout column of the water spout not being formed on account of the extreme dryness of the air which the column. The white squall accompanies the r, and its appearance is sudden, its duration brief, destructive power at times so dreadful that it has known to trip a ship of every sail and mast in a few s, and leave it rolling a helpless log amidst the ious sea which follows it. In sailing through such a close lookout should be made, particularly when ather look singularly fine, the skies beautifully he air calm or nearly so, and the temperature and re of the air on board the vessel noticeably high.

nual Period of Hail.—The hail here referred to is hard, and compact, and in the form of clear or n ice, the hailstones sometimes being found when acro-s to be composed of alternate layers of the e ates of ice. The following figures show the number s it has occurred during the different hours of the Coimbra during the last six years:—

0 2 A.M.	0	8 A.M. to 10 A.M.	3	4 P.M. to 6 P.M.	3
2 „ 4	1	10 „ „ Noon	20	6 „ „ 8 „	1
4 „ 6	2	Noon „ 2 P.M.	15	8 „ „ 10 „	6
6 „ 8	1	2 P.M. „ 4 „	13	10 „ „ Midt.	0

nal period is thus well marked at Coimbra, where ght out of the fifty nine cases have occurred from to 4 P.M. This period is essentially the same as alculated for a large number of places in repre enta nute, care having been taken to limit the inquiry particular hail described above. The important o be noticed in the diurnal period of hail is that the l maximum is about two hours earlier than the um period of thunder storms. The maximum period thunderstorm is when the ascending current from ated land is at its greatest force for the day: but aximum period for hail is some time before the ng current has fully established itself, or at that the day when the vertical disturbance of the phere is greatest, in other words, when atmospheric erature and vapour fall with height at a much greater m the normal. In the higher latitudes hail falls exceptionally during the warmer months of the year. ions where the summer climate is practically rainless l falls; and where the rainfall is small and at distant l few cases of hail occur. Thus at Coimbra, where ain fall in summer, hail was recorded as having only once in the six years during the four dry hot s from June to September.

hail is probably connected immediately with whirl- more or less developed; and it is when the hail- s one of the phenomena attendant on the tornado or eat thunderstorm that it assumes its most destruc- rm. The theory of the formation of hail has been by Ferrel in his *Meteorological Researches for the Use Coast Pilot*, part ii. p. 85. The vapour carried aloft gyrations of the tornado is below a certain height sed into cloud and rain, but above that height into snow. Let the raindrops formed below be carried u the snow region by the powerful ascending currents tornado and be kept suspended there a little while, an become frozen into hail. If now these be thrown outside the gyrations of the tornado, they fall to the as a shower of compact homogeneous hailstones o ice of ordinary size. If, however, they are caught descent and carried in toward the vortex by the in currents on all sides, they are again rapidly carrie into the freezing region. A number of such revo of ascent and descent may be made before they fall earth. While high up in the snow region, the hai receive a coating of snow; but, while traversing the lower down where rain yet unfrozen is carried up receive a coating of solid ice. Thus alternate coat snow and ice are received, and the number of ea indicates the number of revolutions described bef hail-stones fell to the ground. When the nucleus posed of compact snow, as is generally the cas hailstone had its origin high up in the snow regi small ball of snow, or soft hail (*Graupel* in Germa *grésil* in French); but when it is composed of cl throughout it was formed in the rain region, carr into the snow region and there frozen, and imme afterwards fell to the ground.

Monthly, Annual, and Irregularly Recurr Phenomena.

The Temperature of the Sea.—Figs. 8 and 9, rep ing the distribution of the temperature of the water of the ocean for the two extreme months Fe and August, are reproduced chiefly from *The Wi Current Charts for Pacific, Atlantic, and Indian* published by the British Admiralty in 1872.

In February (fig. 8) the temperature of the surface of the to the annual minimum over the northern hemisphere, a to the maximum in the southern hemisphere. The cours isothermals more closely follows the latitudes in the Pacific and South Atlantic Oceans; but the divergence from the great and striking over the North Atlantic. The wider a open the ocean the more does the distribution of the tem approach the normal; and the more confined the ocean the the divergence from the normal. The key to the an distribution of the temperature of the ocean is furnished chart of the distribution of atmospheric pressure and the p winds of the globe. So far as observation has gone it woul that the surface currents are practically altogether cause prevailing winds over the respective oceans, subject to such d in their courses as are occasioned by the land.

In the southern hemisphere the currents on the west sid Indian Ocean flow southwards along the east coast of Afr since the currents here pass from lower to higher latitu temperature along the whole extent of this coast is raised considerably above the normal. On the other hand, since the cu the west coast of Africa flow from south to north—in othe from higher to lower latitudes—the ocean currents which on this coast have a temperature much under the norma winds and currents on the coasts of South America are analogous to those of Africa, and the distribution of the tem of the seas also similar. The temperature of the ocean on coast of that continent is for the same latitudes everywhe than on the west coast. Even in the smaller continent of A the same law holds good.

In the northern hemisphere a different distribution of t perature of the sea is seen at this season. In the Atlantic petature is very much higher on the west of Europe tha east of America. On the east of America from Wilmi Boston occur the most rapid transitions in the mean tempe the ocean anywhere on the globe, the temperature falling short distance from 70° to 30°, whereas on the eastern sid Atlantic these isothermals pass Cape Verd Islands and Spi respectively. In the winter months the prevailing wind east side of North America are north-westerly, whilst in th and eastern portion of the Atlantic they are south-weste pouring along the east coast of America the icy current Arctic regions, but over the central Atlantic and along the shores of Europe the warm waters of southern climate

and south-easterly winds of Scandinavia in winter lower nermals along these coasts A striking feature of the winter nals of the Atlantic is the singularly high temperature along re stretching from Spitzbergen towards the south-west and g in a modified degree as far south as the West Indies In fic this feature of the mid-ocean temperature is much less pronounced, and the excess of temperature on the west of over what occurs in the same latitudes of eastern A great as the difference observable between the two side Atlantic

The highest mean temperature in February (85°) occu Indian Ocean to the south west of Sumatra, and there is a p

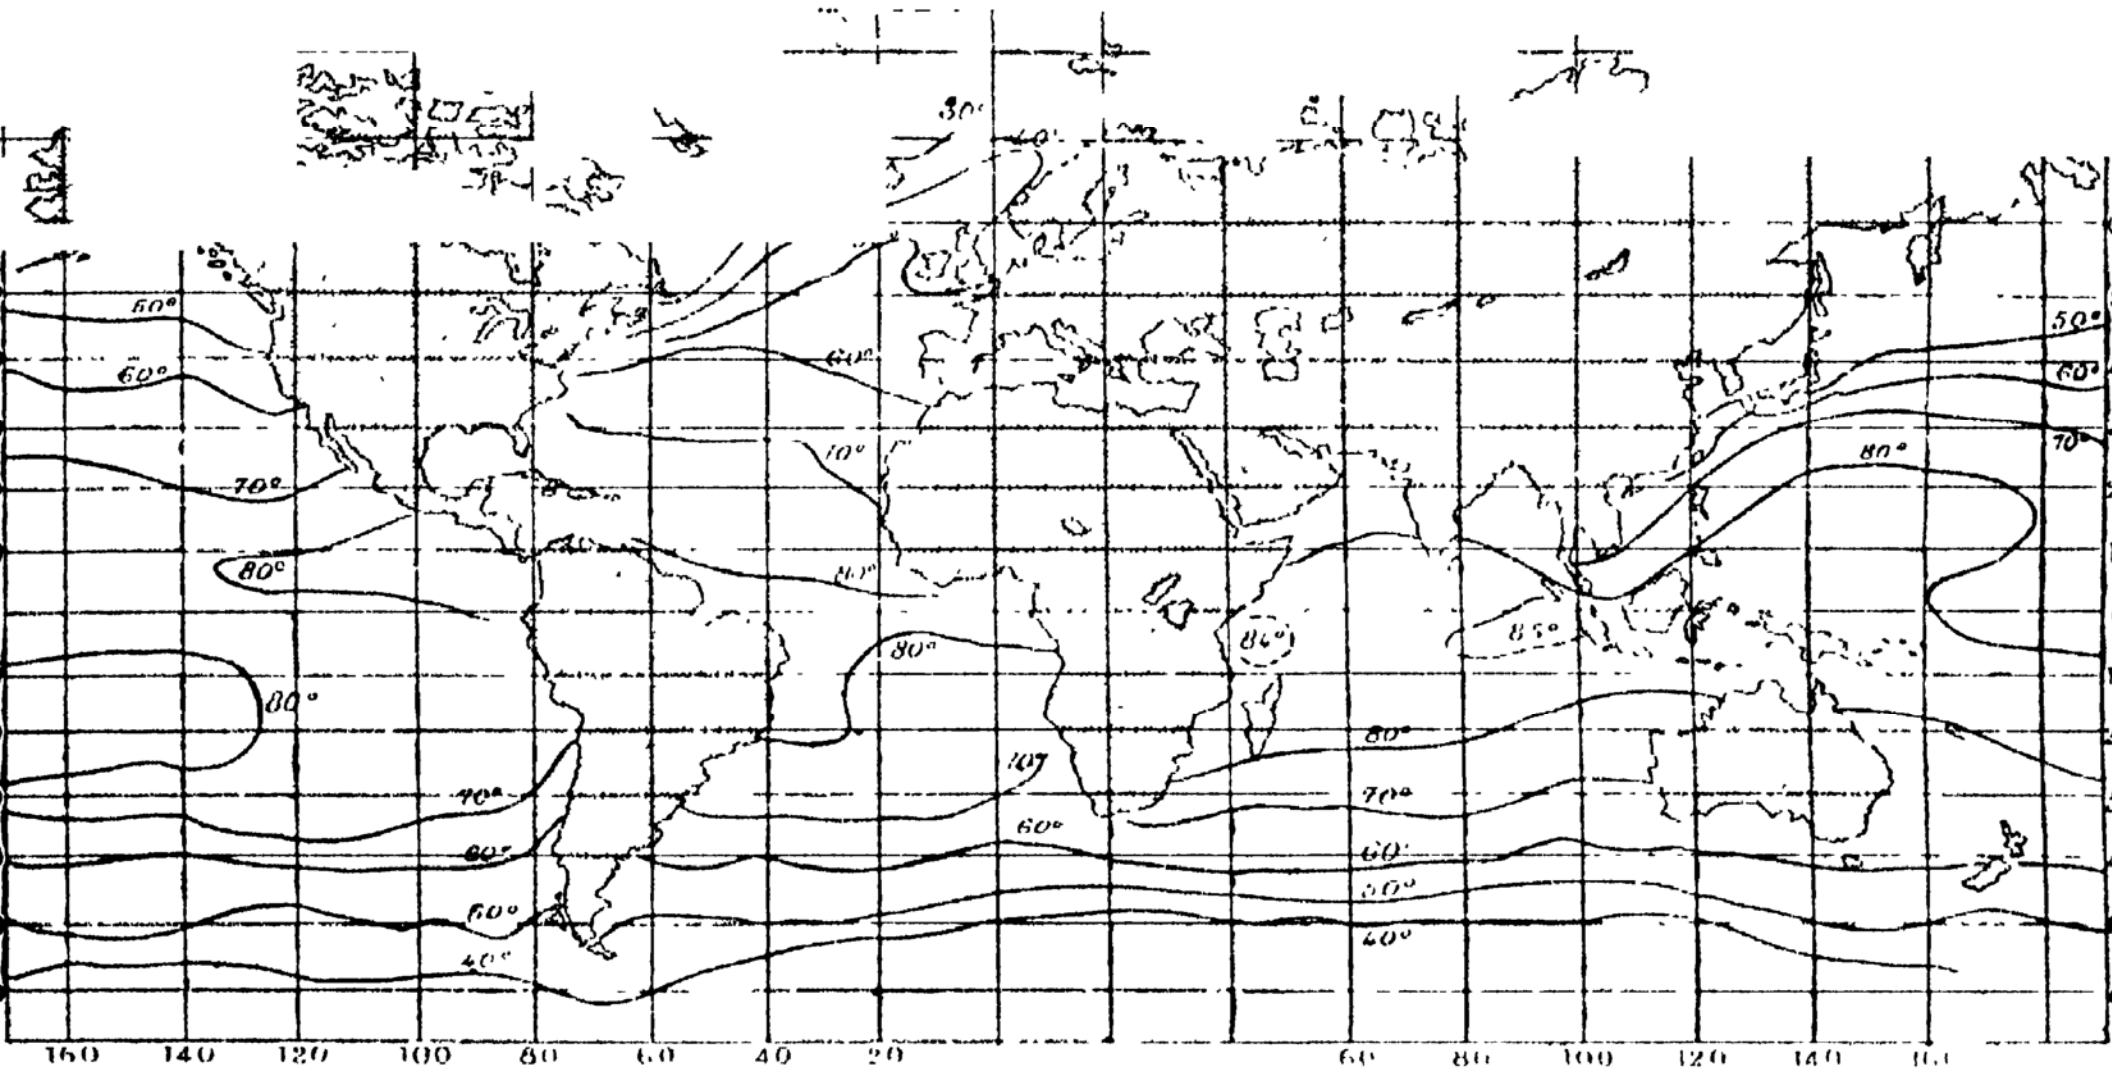

FIG. 8. Isothermals of the Surface of the Sea for February.

ture of which is 84° to the north of Madagascar. The means in the Atlantic are 82° in the north east angle of the Guinea, and 81° off the north east coast of Brazil In the he highest are 83° to the north of the Fiji Islands and 81° Marshall Islands.

In August (fig. 9) the southern half of the Red Sea shows temperature of 90°, being the highest mean recorded for t anywhere at any season Patches showing a summer mea occur in the Chinese Sea to the east of Tonquin, in the Bengal to the east of southern India, about Socotra, and

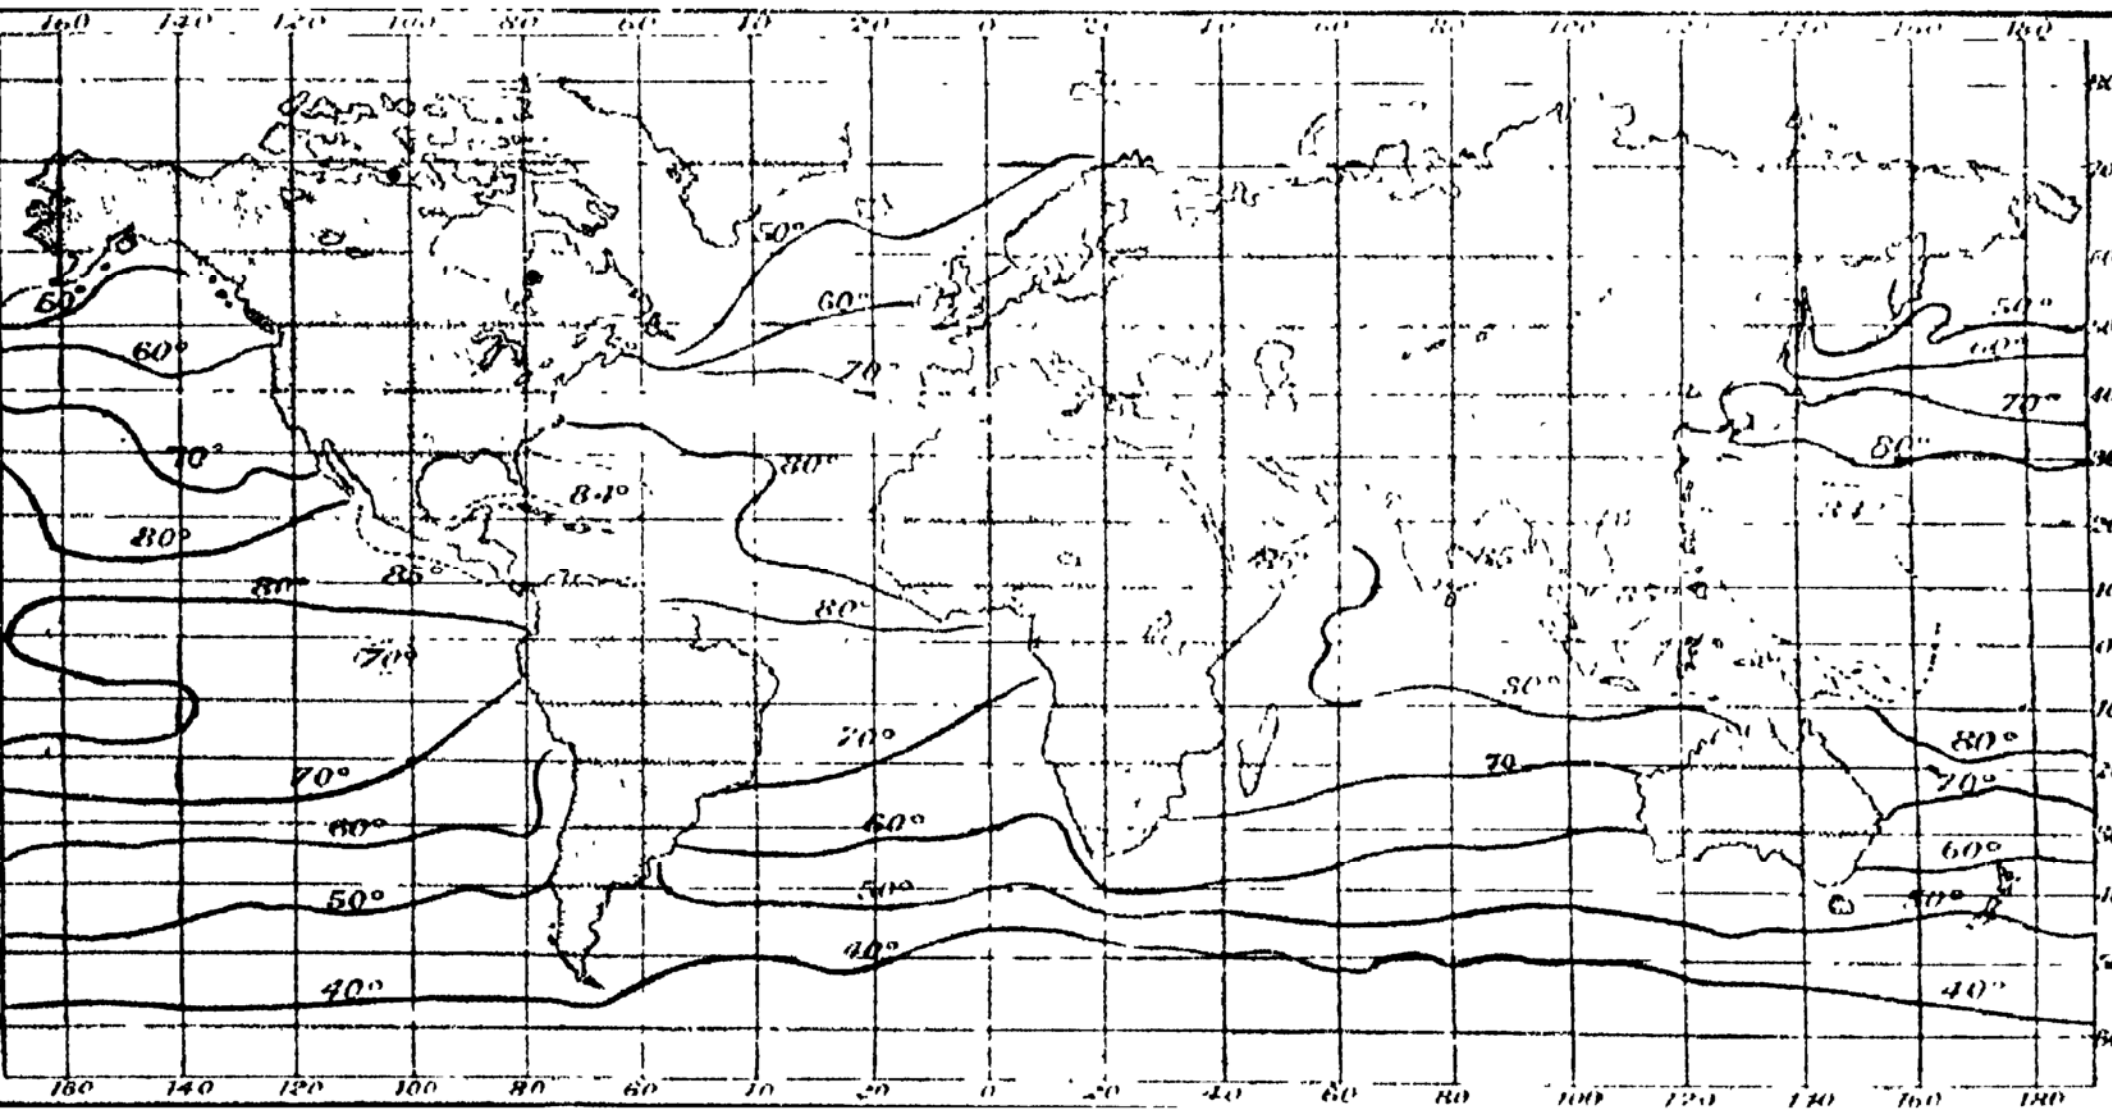

FIG. 9.—Isothermals of the Surface of the Sea for August.

Central America. But the most extensive regions of high ture are in the west of the Pacific between long. 165° the Philippines northward nearly to Japan and south- New Guinea, and the Gulf of Mexico and the adjoining the Atlantic as far east as long. 57° W. A patch of bly low temperature occurs in the Pacific a little to the west of Galapagos, where the mean is only 70°, being 10° lo what occurs anywhere else near the equator at this season,

The influence of currents is strongly expressed in the tem of all the oceans In the south of Asia the monsoons a S., and S E Under the impulse of these monsoonal w extensive surface drift of the waters of the equatorial r

l northwards towards southern A ia, and consequently very
emperature characterize these seas in summer. Its influe-
more the direct on the temperature of the air resulting from
gion of high atmospheric pressure in the North Atlantic at
r on. One of the reflections from the wind blowing all
ions, causing it to arrive part of its journey in the same direc-
Thus to the west of Africa the wind does not arrive from
to south, and hence the temperature of that part of the ocean
ormally reduced. On the other hand, on the west side of this
re area, the prevailing wind does not arrive from south
th, and it will be expected that the temperature of the whole of
ion swept by the southerly wind is abnormally raised. On
other side of the area the wind and current are westerly as
about lone 35 W and hence it is that here the isothermals
the parallels of latitude. In the tropical and northward
ovation wind becomes northwesterly, this propelling northe-
along the western coast of Europe by means of surface drift,
rmer water of southern origin. Meanwhile the currents of
ater and ice from the Arctic regions keep the temperature
ff America to the south of Newfoundland at a figure con
bly lower than observed on any other region in the same
les. In August under relation exists in January between
st and west coast respectively of South Africa, South
a and Australia, all of which have readily explained by the
of mean atmospheric pressure and the prevailing winds
of the most striking fact of ocean temperature is that the
ature of the Southern Ocean from about 50° to 60° S. lat.
tically the same in January and August, a circumstance due
to the preponderant icebergs of that ocean.

Temperature of the Land.—In regions where the
ll is distributed through all the months of the year,
where snow covers the ground for only a small part
year, the mean temperature of the soil nearly equals
of the air. But when the year is divided into wet
ry seasons, and when snow lies during a considerable
on of the year, the mean annual temperature of the
ay be above or below that of the air. The greatest
nce between the temperature of the soil and that of
occurs where the surface of the ground is covered
several months with snow. Snow is a bad con
r of heat and thus obstructs the free propagation of
old produced by radiation downwards into the soil,
e escape of heat from the soil into the air. In this
over a considerable portion of the Russian empire,
mperature of the soil is considerably in excess of that
air. Thus at a place 120 miles south of Archangel
mperature of the soil is 10° higher than that of the
and at Semipalatinsk it is 9° higher.

daily changes of temperature only affect the soil to
s of about 4 feet. The precise depth varies with
ence of the sun's heat and with the nature of the soil.
ally the heat of summer and the cold of winter give
a larger annual wave of heat propagated downwards,
mplitude of which diminishes with the depth till it
s to be perceptible. Principal Forbes showed from
sations on the Calton Hill, Edinburgh, that the annual
ion is not appreciable lower than 40 feet below the
e, and that under 25 feet the change of temperature
gh the year is small. The depth at which the annual
ion ceases, or where the temperature remains constant,
variable depending on the conductivity and specific
of the soil or rock, but particularly on the difference
en the summer and winter temperatures. The rate
ch the annual wave of temperature is propagated
wards is so slow that at Edinburgh, at a depth of 24
the highest annual temperature does not occur till
ry 1, and the lowest till about July 13, thus revers-
e seasons at this depth. At Greenwich, at a depth
feet, these phases of the annual temperature occur
vember 30 and June 1.

e of Everett in the *Report of the British Association* for 1879
mmarizes the results of the observations of underground tem
e. The temperature of the surface of the ground is not
influenced by the flow of heat from below upwards, but is
ned by atmospheric and astronomical conditions. The tem
perature gradient is defined as the rate of increase of the tem
downwards, and it may be taken as averaging one degree Fa
for every 50 or 60 feet, the exact rate in particular cases be
variable. Thus the temperature gradient of the soil is a
times steeper than the temperature gradient of the ai
temperature gradient is steepest beneath gorges and le
beneath ridges, and hence the underground annual isother
flatter than the uneven surfaces above them. This is the
with the uppermost isothermal of the soil, and the f
increase as we pass downwards until at a considerable de
become horizontal. Where the surface of the ground and
thermal surfaces beneath it are horizontal, the flow of heat
ical, and the same quantity of heat flows across all section
lie in the same vertical. In this case the flow across a h
area of unit area is equal to the product of the temperature
by the conductivity of the latter term be used in an extend
so that it includes convection by the percolation of water
as conduction proper, and hence, in comparing different
the same vertical, the gradient varies in the inverse rat
conductivity.

Since the effects of the cold generated by nocturnal
nevertheless accumulate on the surface of the earth, but the
solar radiation are spread to some height by a cending curre
the heated ground it might be expected that the annual
ture of the surface layer of the soil would be lower than th
at resting over them. Observations prove that such is t
spaces which have their source at greater depths than
which the annual wave penetrates have a constant tem
throughout the year, and if they do come from a depth cons
great as this they may be regarded as giving a ve
approximation to the mean annual temperature of the pla
temperature of cellars is often very near the mean annual tem
of the locality; at any rate this temperature may be se
cellar anywhere.

Distribution of Temperature in the Atmosphere.—
larger problems of meteorology, the distribution of te
ture in the atmosphere over the land surfaces of th
was the first that received an approximate solut
Humboldt). But as regards the ocean, which co
three fourths of the earth's surface, the question
monthly and annual distribution of temperature
atmosphere over it can scarcely yet be said to ha
erously looked at. The isothermals of the temp
of the atmosphere which cross the oceans continue
be drawn essentially from observations made on the
and along the coasts of these oceans. The firs
towards the solution of this vital problem in elim
and other branches of meteorology is the construc
charts of mean monthly temperature of the surface
of the sea over all parts of the ocean from which o
tions for the purpose are available. In prosecuti
line of inquiry, excellent work has been done
Meteorological Office as regards parts of the A
between the tropics and the ocean to the south of
and also by the Dutch, French, and German meteoro
With such charts it would not be difficult, by a
comparison during the same intervals of time betw
temperature of the surface of the sea and that of
resting over it, to construct monthly charts of the te
ture of the atmosphere over the oceans of the globe.

In this connexion the whole of the observations of the t
tures of the air and sea made on board the "Challenger" ha
examined, and sorted into one hundred and seventy-four
according to geographical position, and the differences ente
chart of the route of the expedition. In the Southern Ocean
latitudes 45° and 60° the temperature of the sea was low
that of the air, the mean difference being 1°·4. The tem
of the air is here higher owing to the prevailing W.N.W
and that of the sea lower owing to the numerous iceber
south of lat. 60° S. the sea was nearly 2°·0 warmer than
the result in this case being due to the open sea, which ke
higher surface temperature, and to an increased prevalence
higher latitudes of southerly winds, thus lowering the tem
of the air.

The period during which the temperature of the sea e
that of the air was from June 1874 to March 1875, or duri
part of the cruise from Sydney to New Zealand, and thro
East India Islands to Hong Kong and thence to the Ad
Islands. During the whole of this time, except when pas
north of Australia, the sea was much warmer than the

excess being from 2° to 3°, rising even near Tongatabu to of 4°. The climate of the southern part of this extensive t the seasons visited has a large rainfall, much cloud, and ently a comparatively small evaporation and sunshine In hen the "Challenger" passed the north of Australia the was very dry, the sunshine strong, and the evaporation nd there the sea was slightly colder than the air In the between lat. 20° N and 20° S the sea was everywhere the mean excess being about a degree, and in the Pacific lat 30° N. and 30° S the sea was also warmer, the mean eing a degree and a half

e other hand, in the Atlantic from lat 10° to 20° N the on the mean, half a degree colder than the air This region kable for the high pressure which overspread it for the nd currents which flow out in all directions for its clear ong sunshine, and consequently free evaporation, by which perature of the surface of the sea is lowered, and that of esting on it, being open to the heating influence of the sun, is raised. Similarly in the North Pacific from lat. 40° to temperature of the surface of the sea was half a degree low that of the air.

These remarks apply only to the observations made at the open sea Near land very great differences were o which varied with season Thus at Hong Kong during th half of November 1874 the sea was 3°·7 warmer than the low temperature of the air at this season being caused by th temperature of the land and the northerly winds which then on the other hand, at Valparaiso in November and Decembe following year the sea was 3° colder than the air during t week the "Challenger" was there the difference being du of the Humboldt current which sweeps northwards past that co the rapid increase in the temperature of the air at that time year. These results will help us in gaining some knowledg temperature of the air over the oceans of the globe in Febru August taken i temperature of t nexion with a careful examination of nonths represented in figs 8 and 9.

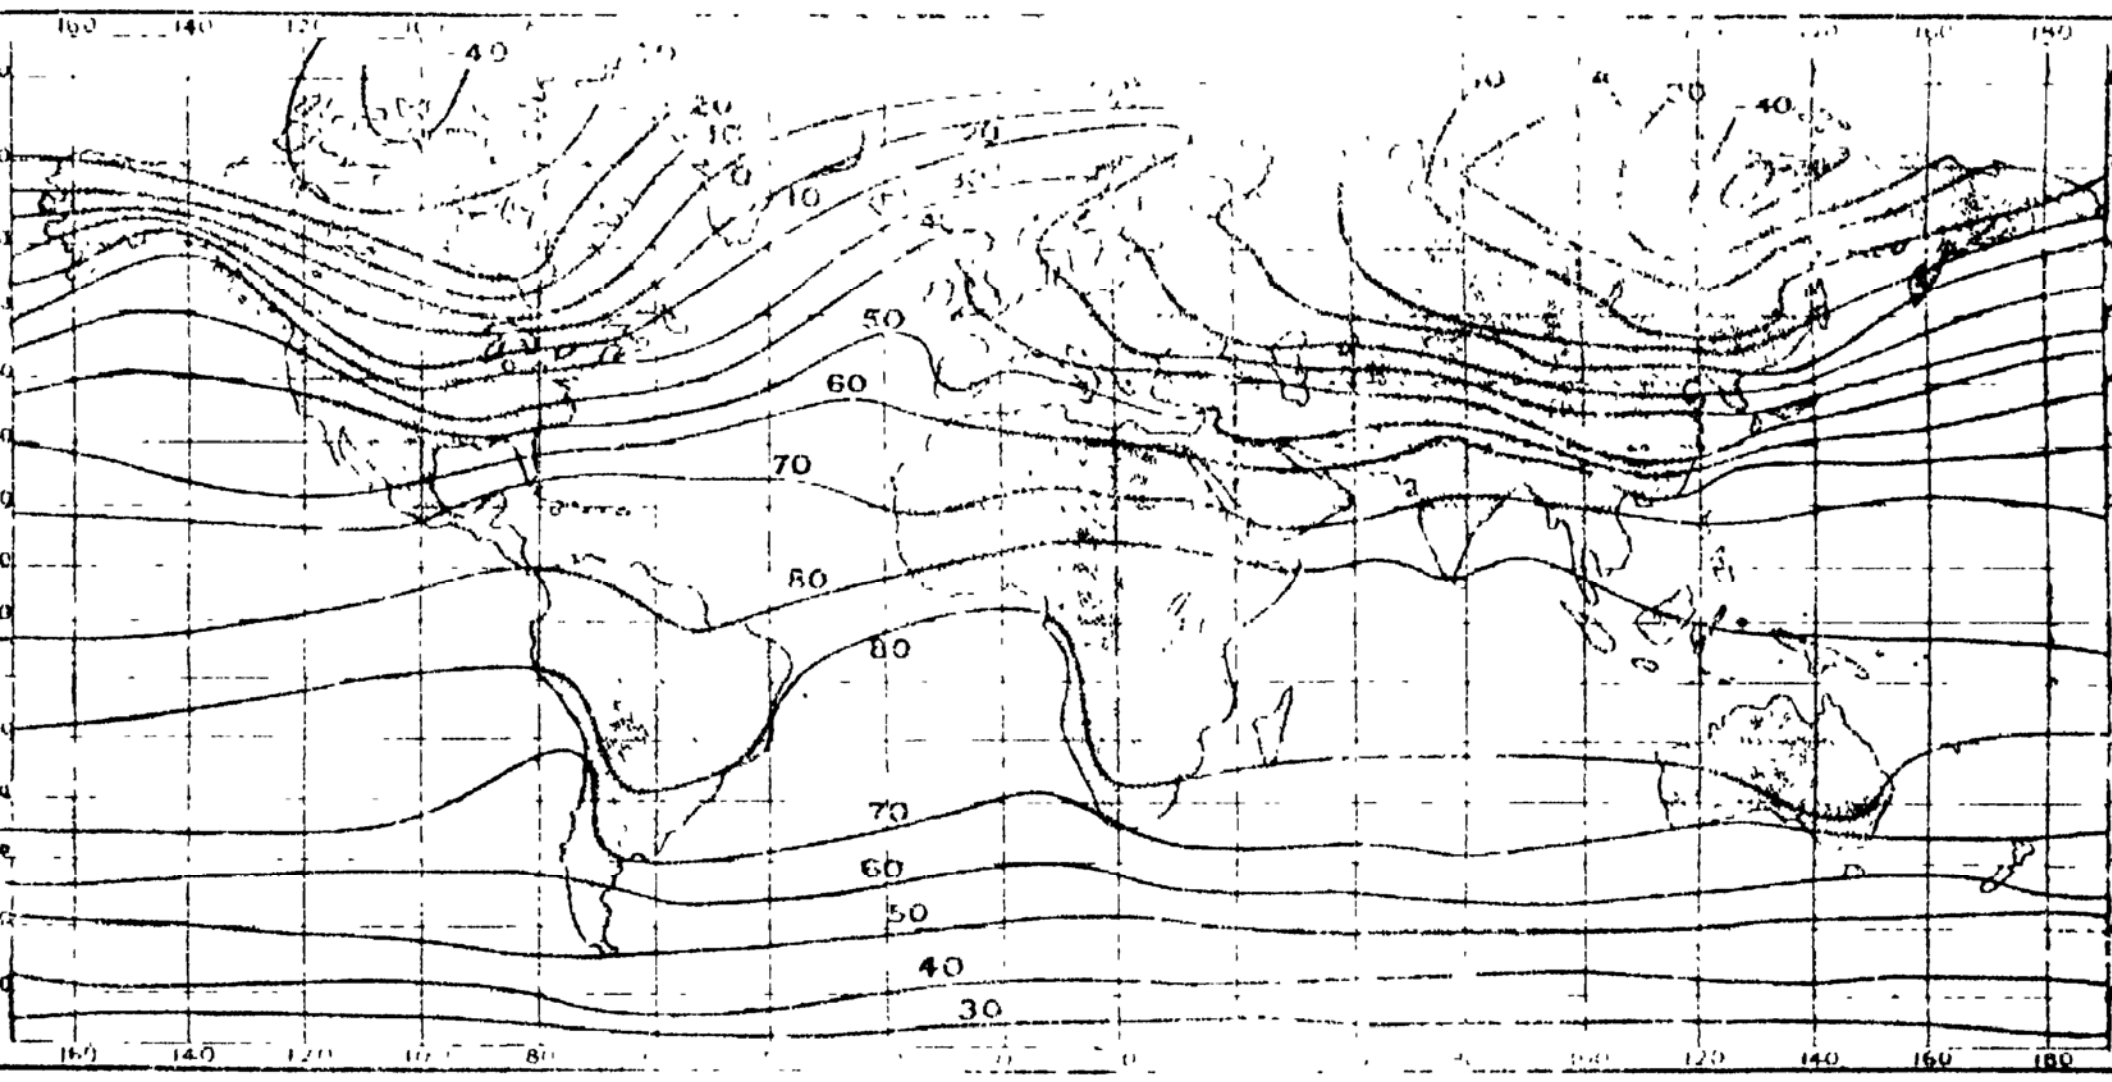

FIG. 10.—January Isothermals of the Surface of the Globe.

distribution of temperature over the surface of the s shown by figs. 10 and 11, which represent the ature of the two extreme months January and July eleven years 1870 to 1880. The region of highest ature, which may be regarded as comprised between th and south isothermals of 80°, forms an irregularly zone, lying in tropical and partly in subtropical es. On each side of this warm zone the tempera minishes towards the poles, and the lines showing ively the gradual lowering of the temperature are, speaking, arranged parallel to the equator, thus g in an unmistakable manner the predominating e of the sun as the source of terrestrial heat. While crease of temperature corresponds in a general way t may be called the solar climate, there are great ons brought about by disturbing causes ong these disturbing causes the unequal distribution and water holds a prominent place. In January rth presents to the perpendicular rays of the sun the niform surface, or the largest water surface, and the most diversified surface, or the greatest extent . Hence the zone of the earth's surface comprised n the isothermals of 80° is less irregular, and also s over an area more restricted, in January than in In July the areas enclosed by the isothermals of nd 90° are much larger in the Old World than New, it being the former which presents the larger land surface to the perpendicular rays of the sun, January, the summer of the southern hemisphere, th extensive area of high temperature seems in Afr the least in Australia, the high temperature area of America being intermediate In contrast to this of temperature exceeding 80° of least breadth w crosses the Pacific and Atlantic Oceans, the a minimum breadth being in July in the Pacific, the ocean, where the disturbing influence of the land is

During the cold months of the year, when the sun is least and the effects of terrestrial radiation att maximum, the areas of cold are over the large surfaces which slant most to the sun Thus the mean temperature that occur anywhere or at any on the globe is 55°·8 at Werchojansk (lat 67° long. 133° 51′ E.) in north-eastern Siberia In America the lowest isothermal is −10°·0 Dur winter the ocean everywhere maintains a high perature in all regions open to its influence, as is only in the higher latitudes to which the isotherma their way as they cross the Atlantic and Pacific, in their irregular course over and near the Mediter Black, Caspian, and White Seas, Hudson's Bay, the of the St Lawrence, the American lakes, and all oth sheets of salt and fresh water. The disturbing in of sheets of water on the temperature in all season strikingly shown when the isothermals are drawn fo

these marking out the prominent features of local s, a knowledge of which is of so great importance to iculturist, the horticulturist, and the invalid. Figs.

12 and 13 represent charts of temperature of this tion for the British Islands for 1870 1880 fr *Jour. of Scot. Meteor. Soc.*, vol. vi. In the winter

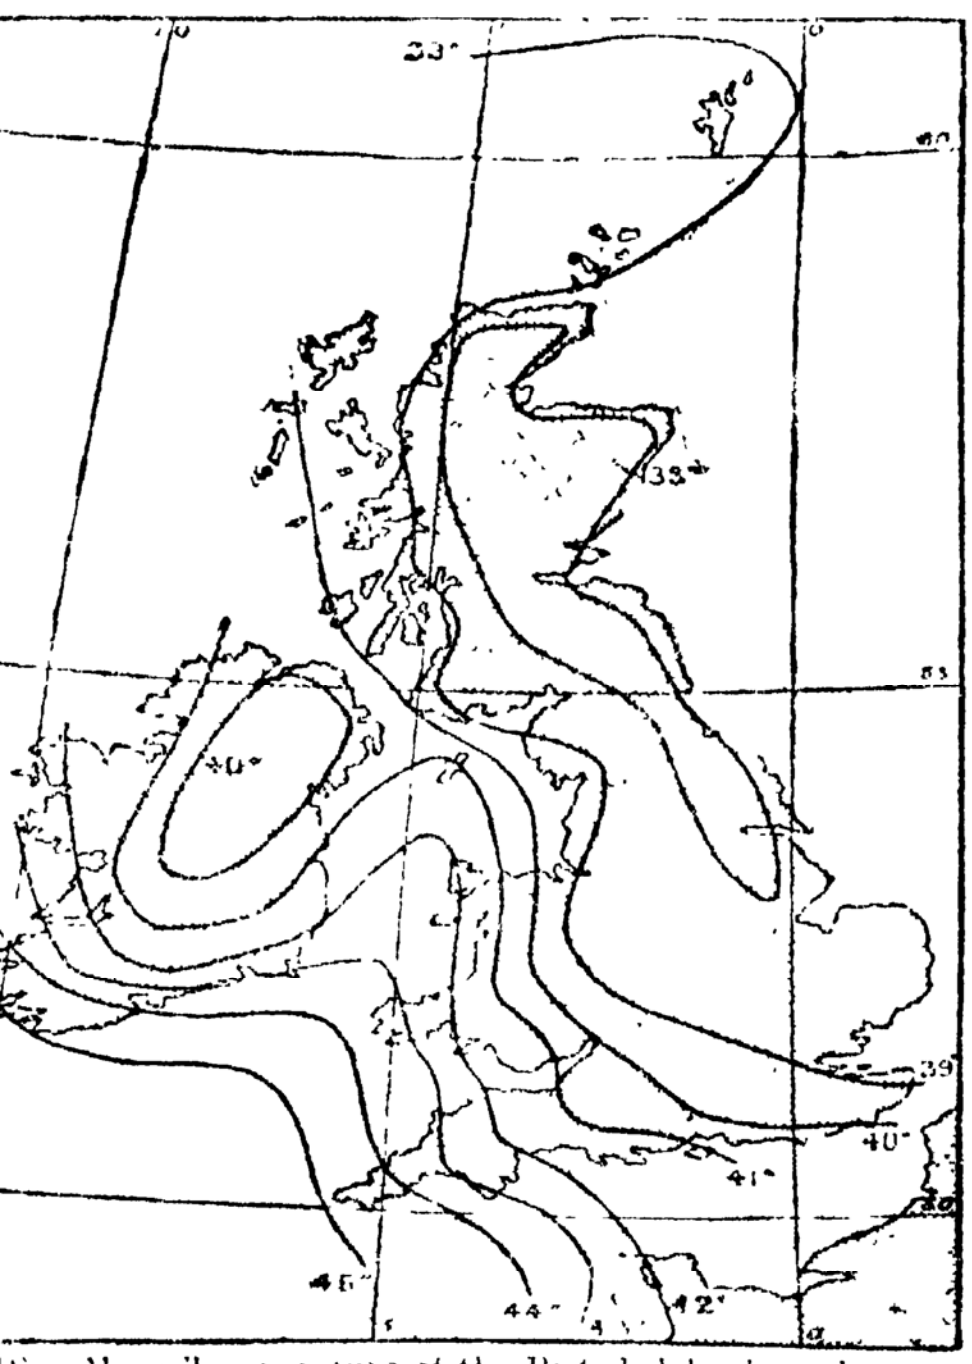
n hemisphere the depressing influence of the land temperature is but slightly felt, owing to the small



Mean Temperature of the British Island in January.

or the land surfaces and the comparatively low s to which they extend southwards. In the south

east of Australia and in the basin of the La Plata, temperature prevails in the interior.

Another prominent disturbing cause operating

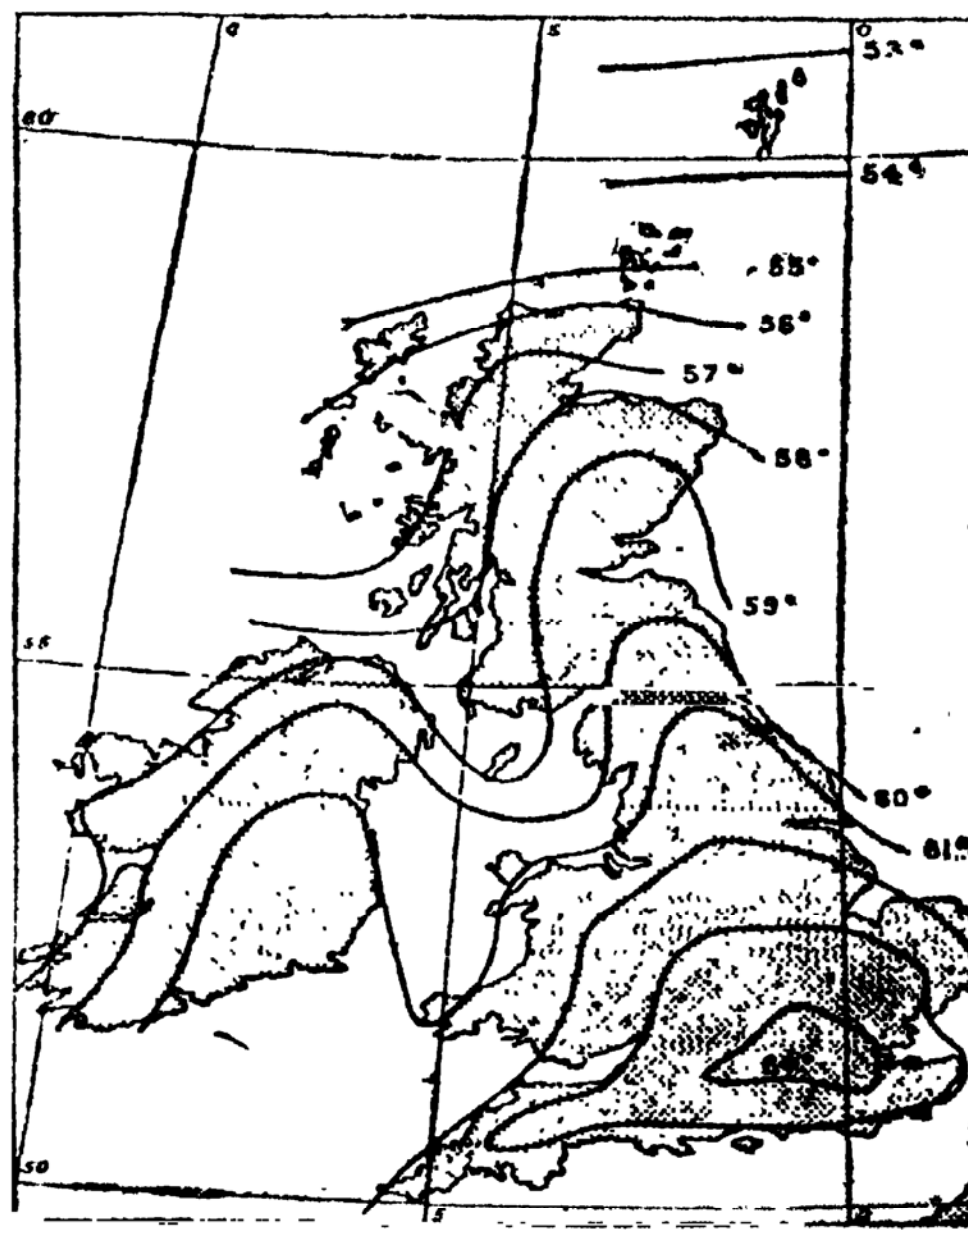


FIG. 13.—Mean Temperature of the British Islands in J

mean temperature is to be found in the seasonal low and high mean pressure in their connexion with vailing winds. Of these the most marked is the sy

low pressure about Iceland during the winter months (see fig. 14). Since this region of low pressure gives to western Europe its prevailing south-west and south winds, and to North America its north west winds in winter, it is plain that the temperature of western Europe is thereby abnormally raised by the simple fact of its prevailing winds coming from the ocean and from lower latitudes, and that the temperature of North America is abnormally lowered by its prevailing winds coming from the Arctic regions and from land. The opposite action of these two winds, which are part and parcel of the same atmospheric disturbance about Iceland, is shown from the fact that while the mean temperature of the south coast of Hudson's Bay in January is −20°, in the same latitude in the Atlantic to the west of Scotland it is as high as 44° or 64° higher. A similar though less striking result accompanies the low-pressure area in the north of the Pacific in winter.

Another area of low mean pressure which powerfully affects the temperature is the low barometer which overspreads the interior of Asia during the summer months (see fig. 17). Since from this disposition of the pressure the prevailing winds of Europe and western Asia are north west and west, and over eastern Asia south east and east, it follows that the temperature is abnormally raised on the eastern side and depressed on the western side of the continent by the direction from which they severally receive their prevailing winds. This is well shown by the course of the summer isothermals of 80°, 70°, 60°, and 50° across the Old Continent.

Since the strongest insolation occurs where the air is driest, the hottest summer climates are met with in those tropical and subtropical regions where no rain falls. The most extensive of the rainless regions during the summer months is perhaps that which extends from the Punjab westwards through Persia, Arabia, and North Africa to Spain. This is the region where the hottest climates of the globe are to be encountered. Similarly no rain falls at this time of the year in lower California and the States adjoining, and this feature of the climate, taken in connexion with the relatively low temperature of the coast due to the winds and ocean currents from the north which sweep past it, results in sharp contrasts of temperature within short distances such as have no parallel in any other climate.

Of the areas of seasonal high mean pressure, the high barometer of Central Asia in winter stands out in characteristic prominence (see fig. 14). Now, since the prevailing winds which necessarily form a part of this feature are south and south-west over Russia and western Siberia, the temperature of these inland regions is considerably higher than would otherwise be the case. On the other hand, since the prevailing winds are north west in eastern Asia, the temperature of these regions is thereby abnormally depressed. It is this consideration chiefly which explains how it is that, while the mean January temperature in latitude 60° and longitude 120° E. is −30°, in the same latitude but in longitude 43° E. the mean temperature is 10°, or 40° higher, even though both regions are equally continental in their character.

The high mean pressure in the summer in the Atlantic between Africa and the United States has with its system of winds the most decided influence in bringing about the abnormal distribution of the temperature of that and adjoining regions. Since on its west side the prevailing winds are necessarily southerly, the temperature of that region is abnormally raised, and, on the other hand, since on its east side the winds are northerly, the temperature of the region is abnormally depressed. The result of these two opposite winds is seen in the slanting direction of the isothermal of 80° across the Atlantic, which direction is continued far into the interior of North for the reasons already stated.

These important bearings of cyclonic and anticyclonic areas on temperature and climate may be thus summarized. The temperature is abnormally raised on the east sides of cyclonic areas, and abnormally depressed on the west sides; but, on the other hand, temperature is abnormally depressed on the west sides of anticyclonic areas and depressed on their east sides. In the southern hemisphere the conditions are reversed.

Another set of influences, powerfully affecting temperature, come into play where the surface of the land rises above the sea into elevated plateaus, lofty table-lands, or mountain ranges. Thus it has been observed on Ben Nevis and other mountains that the wind during the day in summer exhibits an ascensional tendency due to the circumstance that the temperature of the surface of the mountain is heated in a much greater degree than the air or strata at the same levels all around it. An ascending current consequently rises from the mountain, which is maintained at a steadily stronger rate than at lower levels because the drain from the updraught is easily supplied from the free surrounding atmosphere. It is this excessive insolation at high elevations in the summer months which explains the excessively high day temperatures encountered in the Rocky Mountains, and from the same cause, viz., the rarity and purity of the atmosphere, by which terrestrial radiation is but little checked, come the low temperatures of the nights of these climates in the summer season. From this cause it follows that the elevated regions in the interior of continents tend to reduce mean atmospheric pressure in summer to a greater extent than would otherwise be the case. In winter, on the other hand, the temperature of elevated regions in the interior of continents is very much colder than that of the surrounding atmosphere at the same heights, because in such regions the air is exceedingly dry and rare, and consequently radiates into the cold regions of space but little checked. Hence on the slopes of these high lands there are powerful directions descending currents of very cold air which intensify the rigours of the winters experienced on the lands round their base, where accordingly the lowest winter temperatures occur. These elevated lands also materially add to the high atmospheric pressure in the interior of continents during the cold months of the year.

But it is ocean streams and ocean currents which produce the greatest abnormalities in the distribution of the temperature of the air, and a glance at figs. 10 and 11 will show that it is in the North Atlantic where this cause is most strikingly seen. The increase thus accruing to the mean temperature is greatest about the north of Norway, but also very great in the British Islands, thus, if the heat were received than is due to their position on the globe in respect of latitude, the mean winter temperature of Shetland would be 3° and that of London 11°, mainly owing to the heat given out by the Gulf Stream and other warm currents of the Atlantic their mean winter temperatures are respectively about 39°·5 and 39°, being thus benefited 36°·5 and London 22°. The high winter temperature of the British Islands well illustrates the influence of the surrounding ocean in maintaining a higher temperature. It will be seen that the south coast of Ireland is 7° warmer than the east coast of England in the same latitudes. The strong drift current from Behring's Strait southward along the coast of America has a powerful influence, particularly in lowering the winter temperature of that coast, thus bringing about, in conjunction with the dry rainless climate of the interior, what are perhaps the most violently contrasted climates

limits, as regards their temperature. The deflexions isothermals near the Baltic, Mediterranean, Black, aspian Seas and the freshwater lake of America nt to the disturbing influence of the sheets of on the temperature

height and direction of mountain ranges is an ant element in determining climate If the ranges pendicular to the prevalent wind and of a con le height, they drain the wind of much of their e, thus cause to place to leeward colder winters tter summers, by partially removing their protecting of vapour, and exposing them more completely n and terrestrial radiation Of this Norway and n and the British Island form excellent illustrations hin that makes the most important distinctions climate in regions near each other, as respect both and vegetable life With regard to the decrease of ture with height, very much yet remains to be done an approximation to the law of decrease can be

During the five months observations were made n Nevis in the summer of 1881 the difference n the mean temperature at sea-level adjoining and top of the Ben, 4406 feet above the sea, was 15 7, how a mean decrease of 1 Fahr for every 280 elevation The actual differences from day to day from 1 1 to 23 2 As Ben Nevis forms a peak, in the very middle of the strong winds from the r, it is highly probable that this rate of decrease is approximation to the true decrease of the tempera the air during the summer months in that part of itish Islands When observations are made on l plateaux of some extent, the rate of decrease l from the observations will be less than the true the free atmosphere in summer and greater in The rate is thus a variable quantity, varying with , situation, dampness or dryness of the air, calm or weather, and particularly with the season of the One degree Fahrenheit for every 300 is the rate of generally assumed

ount of Aqueous Vapour It is scarcely possible to mate the importance of a knowledge of the hori and vertical distribution in the atmosphere of its vapour, for it may be truly said that it forms one prime factors in all the larger problems of atmo physics A first rough approximation to the ac- al distribution of the vapour of the atmosphere was d by Mohn in 1875 in his *Grundzüge der Meteoro* 81, in which vapour pressure curves are drawn for ne for January and July. These leave much still one, not only in a further discussion of observations made, but also in improvement of the methods of tion and in the tables for their reduction. The nt of interest in Mohn's vapour curves is their e resemblance to the isothermal of the same months, which goes to show that this line of inquiry is yet des- to make large contributions to our knowledge of the ne change which occur in the pressure, temperature, ture, and movement of the atmosphere.

less is known of the vertical distribution of aqueous It decreases, like temperature, with the height, the statement generally made be at all correct, that the whole vapour of the atmosphere is contained in est 6000 feet, and that at 20,000 feet high there is bout a tenth of what is at the earth's surface, the rate ase with height proceeds at a greatly more rapid rate consistent with the supposition that it forms an ndent vapour atmosphere existing under its own e. The establishment of an increased number of vel stations, and a more systematic inquiry than has en attempted into the upper currents of the atmo sphere, are much needed in the further development branch of meteorology. In carrying out the i invaluable assistance will be obtained from observa the diurnal range of the barometer and from well- methods of observing the effects of solar radiation earth's surface.

Amount of Cloud. In Scotland, which lies com within the region swept by the south westerly win the Atlantic, and presents a well-defined mountain lying across the track of these winds, the clouds distinct annual period. In the west, at places qui to these westerly breezes, the amounts of cloud in summer, autumn, and winter are respectively 67, and 74, and the annual mean 70.[1] In the east, districts as East and Mid Lothian, which have ex ranges of hills between them and the Atlantic, the tions are 59, 63, 62, and 60, and the annual me Thus about a tenth more of the sky is covered wit at the western as compared with the eastern situatio the distribution of cloud differs materially in weste eastern climates In the west winter is the cl season, but in the east it is summer, and these are tively the months when most rain falls in the climates. Everywhere spring is the season when is clearest. In England, owing to the protection a by Ireland and Wales to the west and the comp absence of ranges of hills, the amount of cloud is le in Scotland, and it is more equally distributed o country. The minimum amount occurs in spring, a maximum in winter and autumn.

Some of the best illustrations of the seasonal variation distribution of cloud are afforded by the Old Continent variations are the simple consequence of the systems caused by the high winter and low summer pressures of th ment. In eastern Siberia the prevailing winds in winter a or continental, and in summer S E. or oceanic, and acc at Yan, Nertchinsk, and Blagoweshtchensk the mean of cloud in these two seasons are 18 and 11. On the oth in western Siberia and eastern Europe the prevailing w winter are S W., or from lower to higher latitudes, summer N W, or from higher to lower latitudes. Kazan taken as fairly representing this extensive region and t amount of cloud for the four seasons beginning with are 71 48, 44, and 62. As the N.W. winds of summer r the Ural mountains in their course, condensation of the vapour is increased, and hence over this region the cloud i and summer is nearly the same, the mean amounts at Bog Ekaterinburg, and Zlatoust being respectively 53 and 52. and Kutais, situated on the high ground which lies betw Black Sea and the south of the Caspian Sea, the means fo and summer are 53 and 55 On the eastern coast of the B the westerly winds of summer are accompanied with the maximum cloud, the winter and summer amounts at Re being 59 and 69 In Central Siberia, to which the S.W. winds do not extend, and to the north of latitude 55°, the of cloud is much diminished, and the cloudiness of summer i the same as that of winter.

In India, in all regions which lie open to the summer m the minimum amount of cloud occurs during the win the maximum in summer,—the mean amounts being 19 at Calcutta, 16 and 86 at Bombay, 18 and 71 at Colom 25 and 90 at Rangoon At Trincomalee, on the east Ceylon and thus exposed to the rains of the N.E. m of winter, and largely protected from the rains of th monsoon of summer, the amounts of cloud in these seasons and 59. At Darjiling (6912 feet) and Chakrata (7022 feet both on the Himalayas, whither the summer monsoon pen the mean amounts are respectively 53 and 86, and 43 and Leh, in Kashmir, the amounts are 59 and 51, the excess be in winter In the Punjab and to westwards, or those reg southern Asia to which the summer monsoon does not exte cloud in winter is everywhere greater than in summer. T amounts are 21 and 18 at Mooltan, 38 and 25 at Peshawar, 19 at Jacobabad, and at Quetta, in Baluchistan, 5500 feet and 14 Similar relations as to cloud obtain in Australia other continents where high pressures rule in the interior

[1] In this section the amount of cloud is stated in percentage sky covered with cloud

months and low pressures during the warm months of the
The maximum cloud occurs with winds from the sea and
lvancing into the colder regions of higher latitude, and
mum with winds which have traversed an extensive track of
winds advancing into the warmer regions of lower lati-
As the subject, however, is essentially one with rainfall, it

annual movement northward and southward with
as already explained. To seasonal movements
ascribed part of the cloudiness of the southern and
sides of the winter cyclonic regions of the North
c and North Pacific, and of the cyclonic region of
mmer pressure in the interior of Asia and other
nts. On the other hand the comparatively small

amount of cloud in the anticyclonic regions of the A
and Pacific Oceans, and in the high pressure regions
interior of Asia and other continents during the cold
of the year, is due to the vast down-currents which
the centres of the anticyclones, and which
relatively drier as they descend owing to the in
pressure to which the air is subjected.

Distribution of Atmospheric Pressure.—The impo
of a knowledge of the distribution of atmospheri
sure, or of the mass of the atmosphere, over the
in its varying amounts from month to month i
evident. Observation teach us that winds are

they traverse, isobaric maps may be considered as f
ing the key to the more important questions of m

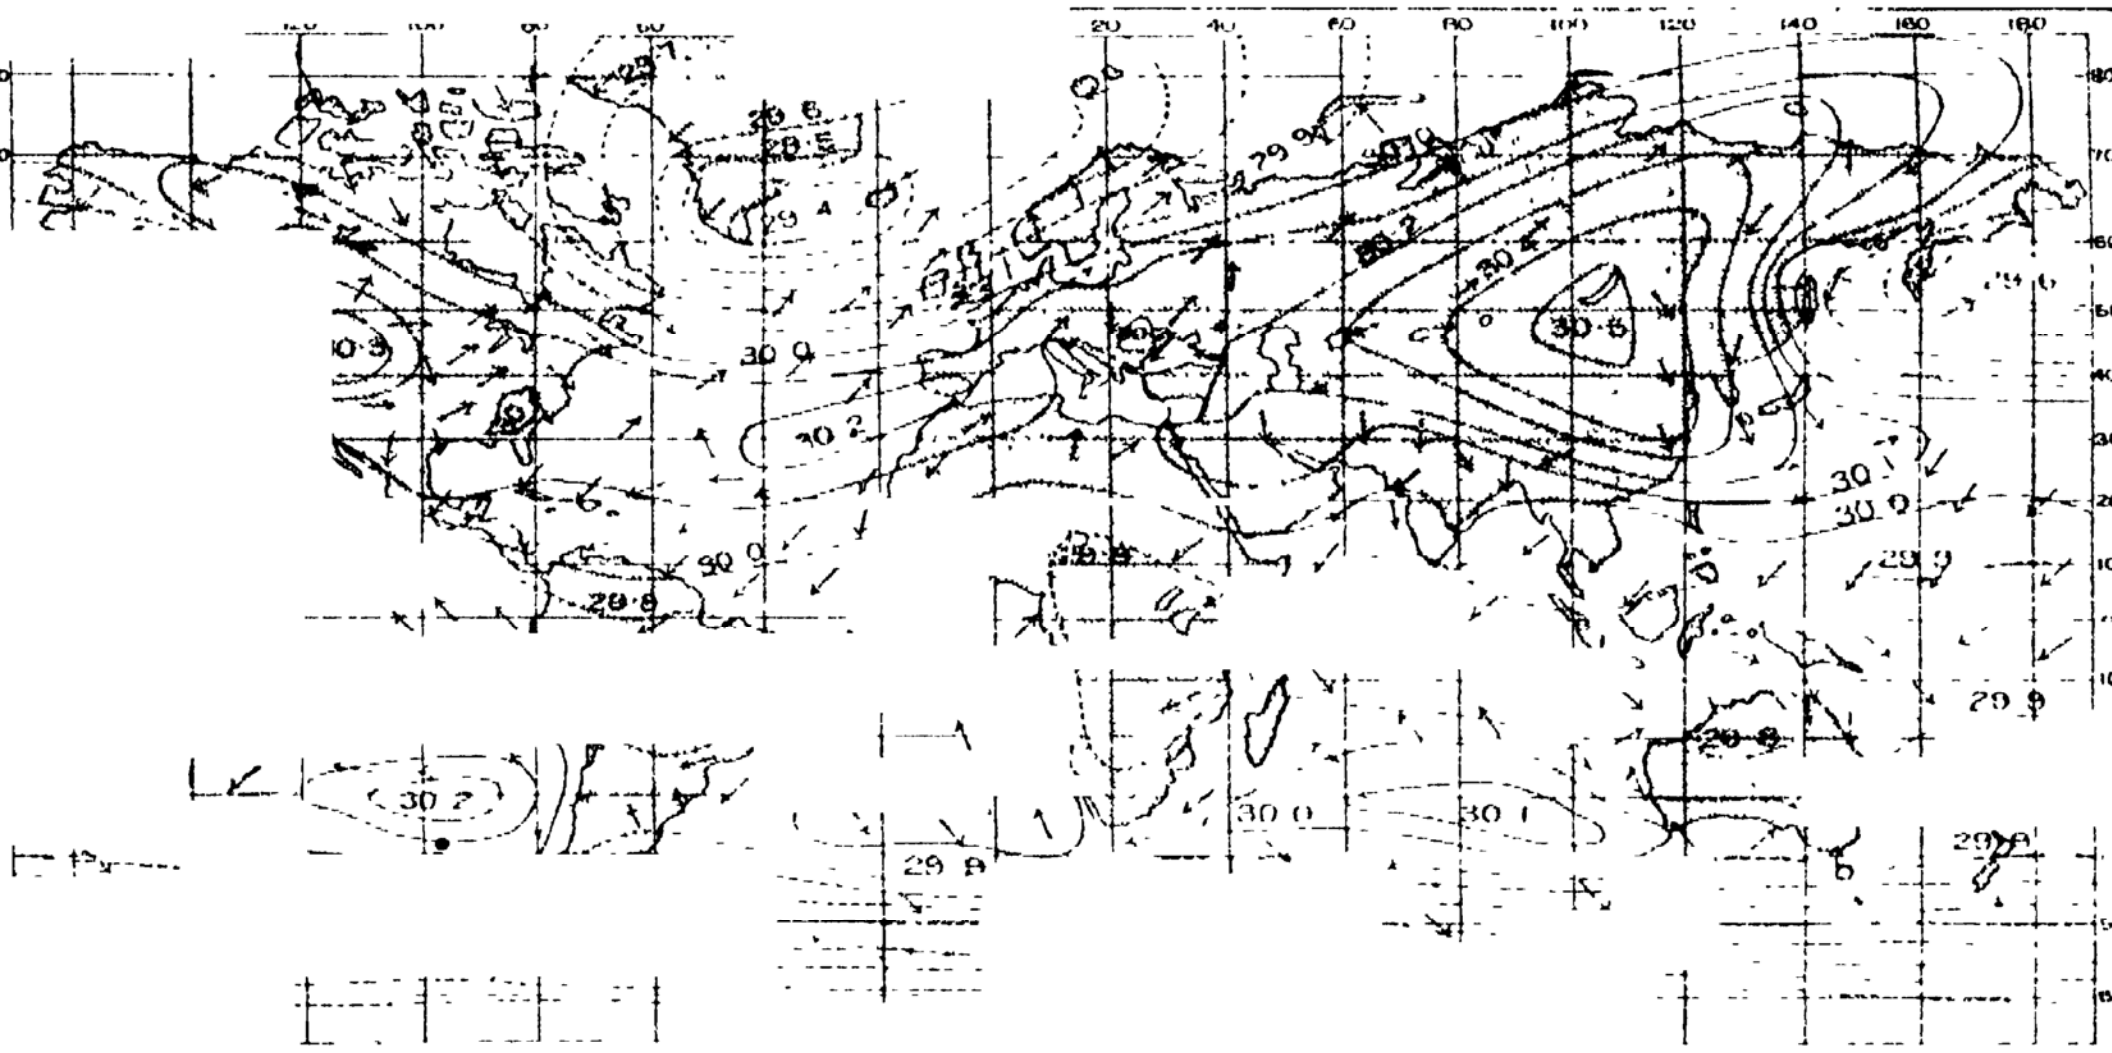

FIG. 14.—January Isobars of Globe and Prevailing Winds.

inquiry. At the time of the first publication of
maps of the globe in 1868, it was impossible to
re than present the subject in its broad general
s, owing to the scantiness and quality of the
ls then existing. But since then meteorological
s have been largely multiplied in all parts of the
d world, and the general adoption of the issue of
warnings has necessitated the use of more accurate
eters and uniform methods of observing. Since
s thus now the means of a more exact representation
s fundamental datum of meteorology we have
ed a new set of isobaric maps, showing the distribu
the earth's atmosphere and the prevailing winds
nuary (fig. 14), July (fig. 17), and the year. They
been constructed from mean values calculated for the
eleven years (1870–80 inclusive) as the isothermal
igs. 10 to 12, pressure of 30·0 inches and upwards
represented by solid lines, and of 29·9 inches and
by dotted lines, while the arrows show the directions
prevailing winds at the localities indicated by the
tive arrow-points.

Mean Atmospheric Pressure in January (fig. 14).—In this
when the influence of the sun on the northern hemisphere
the minimum, the greatest pressures are massed over the co
of that hemisphere, and
est pressures over the northe
of the Atlantic and Pa
Ocean, over the Antarctic Oc
southern hemisphere generally. In the southern hemisphe
are three patches where pressure rises to 30 inches, viz.
Atlantic between South America and Africa, south of the
Ocean, and in the Pacific between Australia and South Am
In the northern hemisphere, on the other hand, pressure
Central Asia to upwards of 30·5 inches, the mean pres
nary being at least 30·4 inches at Peking, Semipalatin
and fully 30·5 inches at Irkutsk and Nert
upper basin of the Amur. This is the region wh
normal atmospheric pressure attains to a maximum v
much higher than is reached in any other region at a
time of the year. It will be observed that the
highest pressure occupies a position near the centre of th
continent. The area of high barometer is continued w
through Europe, through the horse latitudes of the At
Carolina, and thence through the United States to C
whence it crosses the Pacific to Asia. The belt of high
thus completely encircles the globe, broadening as it pa
land and contracting as it crosses the ocean. Its greatest
is over Asia and at least over the Pacific, or where
ocean attain respectively their maximum dimensions.

res greatly under the average cover the northern portions
ne the and Atlantic and also the greater part of the Arctic
In the north of the Pacific the normal pressure falls to
29 6 inches between Kamchatka and Alaska In the
the Atlantic, however, a still lower mean pressure obtains
narrow belt stretching from Iceland to the south of Green-
e normal at Stykkisholm in the north west of Iceland being
nches and at Ivigtut in Greenland 29 61 inches This
ge for Ivigtut is the lowest monthly mean to occur any-
nd at any season in the northern hemisphere, and it is
nt that the places immediately to the north of that part
Atlantic where cyclonic disturbances of the storms which
ver Europe have their origin and where not a few of the
which cross the Atlantic to Europe develop intensity
been seen that the lowest mean pressure occurs near the
f the Irish Sea but as regards the two oceans
west pressure is met with in the northern division of the
, which is the lower ocean An inspection of fig 14 shows
that the low pressure area of the Atlantic is bounded to
nd by systems of much higher pressures than are to be
the Pacific The result of this arrangement is that much
winds flow northward over the Atlantic and round upon
, and, as the more quickly advance into colder latitudes,
ting a greater and more frequent concentration of vapour
ence of the barometer in the north of the Atlantic The
mate of north western Europe may be referred to as con
this view

of low pressure presses through the equatorial regions
und the globe This marks the well known region of calms
which on either hand the trade winds blow In the
it lies quite north of the equator even in January, when
s nearest is furthest to southward, and it lies nearly parallel
equator On the other hand, in the Indian Ocean the
of the line of lowest pressure to the south of the equator
parallel with it, but taking a fruitless course from near the
Madagascar towards Sumatra, thence towards the low pres
h prevails at this season in Australia, its course is then a
northwards, and across the Pacific to the central regions of
merica It path is thus a devious one, being north of the
only in the eastern part of the Pacific and in the Atlantic,
where to the south of it, being drawn farthest southward
nder the influence of the regions of low pressure which now
central Australia, central and southern Africa, and central
America In this trough of barometric depression nearly
ropical storms of the Indian Ocean have their origin
are several important modifications of the isobaric lines
nally published In 1865 the region of lowest pressure in
hern hemisphere in winter was represented as extending
land to north eastward, now the area of lowest pressure
o extend from Iceland south westward to Greenland. In
on with the point Captain Hoffmeyer discussed the
of the North Atlantic during several winter months, and
d the result in 1878, which conclusively showed that the
logy of Greenland and Iceland exerts on the distribution of
ric pressure a powerful influence not before properly recog-
sulting in the mean minimum of pressure being located
y to the south west of Iceland, and that in addition to this
n there are two subordinate minima, one in Davis Straits
other in the Arctic Ocean midway between Jan Mayen and
ern Isles The investigation further established the fact
o any particular one of these three minima plays an
t part the other two either do not appear at all or occupy
subordinate place, and that according as one or other of
ric pressure predominates so is the character of the
and mildness or severity of the winter of north
regions surrounding the North Atlantic As
Greenland the displacement of the minimum to west
the prevalence over it means milder winter weather,
on the direction of the north of Norway
important consequences seen in the
area of one, two distinct centres of
either the high pressure of the
separated from that of the south
low pressure occupying the region
Mississippi States Professor Loomis first drew attention to
ularity in [illegible] into the distribution of
over the United States established the fact that there
distinct areas of high pressure the larger having its centre
and the less over Pennsylvania the greater portion of the south-
and southern States, and that these two areas of high pres-
clearly separated from each other by a broad extensive
of lower pressure stretching in a south-western direction from
ion of the great lakes to western Texas The reason
by Professor Loomis is undoubtedly correct, that the
ly low normal pressure of the Mississippi States is due to
that the path usually taken by the barometric minima of
American storms in the earlier part of their course is from
the lakes Since, on the other hand, the centres of compa
few storms, with their low barometer readings, cross the s
and south eastern States, the normal winter pressure is high
than it is along the Mississippi.

Another important modification occurs in India, where th
of 30 inches is deflected to the south east toward Mad
thence towards the north east to near Akyab in Arakan
remarkable deflexion well shows the important influence ex
the course of the isobar by large well-defined sheets of wa
extensive tract of land The distribution of pressure here in
by which south of lat. 22 the normal pressure is cons
higher in the east than in the west of India, has, through the
of the winds resulting from it, the most intimate and vital
on the distribution of the winter rains and temperature o
siderable portion of India; and the same relations hold, t
degree still more striking, in the meteorology of Ceylon.

The remarkable effect in interrupting or changing the
the isobars is perticularly well illustrated by the lines in th
of the Aral Caspian, and Black Seas As the point is of
importance in meteorology, and is best illustrated by the

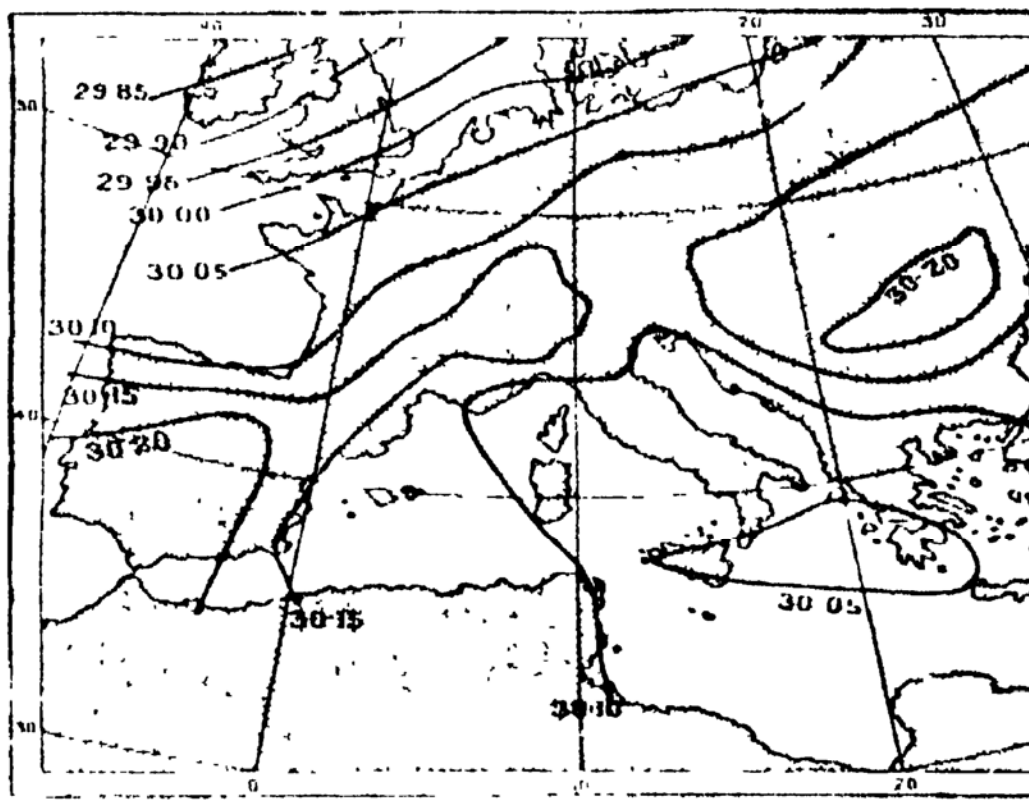

FIG. 15. Isobars of Europe for January.

ranean and the countries to the north of it, we subjoin a ma
part of Europe (fig. 15), showing the normal pressure with
distinctness and fulness than could be shown on fig. 14, the
being drawn for every half-tenth of an inch.

Here we see two distinct areas of high pressure, the
Hungary and the other in the Peninsula, where the normal
exceeds 30 20 inches The latter is the larger of the two, a
be regarded as the prolongation of the region of high pressu
characterizes the Atlantic immediately to the south west
season The high pressure area included within the isob
inches is of peculiar interest. In the Peninsula it covers
broad area, but to the north-east it contracts to a narr
between the Bay of Biscay and the Gulf of Lyons, and again
to north eastward covering the distance from Carlsruhe to
its prolongation eastward being there somewhat sudden
impeded At some distance to the eastward the second region
pressure is met with, which is properly a part of the high
that overspreads the interior of the Old Continent in the
months, its western limit being the isobar of 30 15 inche
presses round by Pinsk, Cracow, Vienna, Laibach and th
southern slopes of the basin of the Danube, Sebastopol, an
southward in the direction of Cyprus.

The position of the latter of these regions of high pre
approximately midway between the south coasts of Asia M
the Baltic In other words, its position occupies the interi
part of the Old Continent; and it is instructive to note
portion of the Black Sea and the Greek archipelago in t
portion of this region pushes the isobar of 30 15 inches a g
to northward The position of the region of high pressur
Peninsula, France, and Switzerland is also decidedly inl
does not, however, exactly occupy the middle space of
lying between the Mediterranean and the North Sea, o
doubt to the circumstance that the very steep barometric
from France to Iceland greatly lowers the pressure over th
of the northern half of France It follows that the ab
high pressure which so remarkably characterizes the interi
Old Continent during the cold months of winter is repr
though in a greatly reduced form, westwards through the
districts of that continent.

These two regions of high pressure are separated from ea

ge area of comparatively low pressure overspreading the
ortion of the Mediterranean Sea, marked off in fig 15 by
r of 30·10 inches, within which pressure is everywhere less
·10 inches. This region includes an area of still lower
within the isobar of 30·05 inches, bounded by Sicily,
thens, and Crete. Hence the singularly low pressure which
rizes the northern part of the Atlantic at this season in its
in the south of Europe, which is unquestionably due to
ner temperature and larger humidity of the climates of
Europe which they owe to the Mediterranean.

leserving of special notice that, while the increase of the
ressure of January from Genoa to Geneva is 0·081 inch,
ly 0·021 inch from Trieste to Riva, and that to the north
driatic as far as latitude 50° pressure is considerably lower
ains to the west and east of that region. An examination
aily weather maps of Europe shows that not unfrequently
ns of north-western Europe on advancing as far to east
Denmark seem to connect themselves in some degree with
anean storms prevailing at the time through a north and
olongation of a system of low pressures. The comparative
y with which this occurs is probably occasioned by the
drift to eastward of the atmosphere of Europe considered as
, taken in connexion with the high mountainous ridge
unds the Adriatic on its eastern side, from which it follows
air overspreading the deep basin of the Adriatic is often
saturated with vapour, and thus highly saturated air
northwards through central Europe when north-west
f Europe with low barometric depression centres pa across
s and the Baltic. Thus the low normal pressure to the
the Adriatic, separating the two regions of high pressure
ast and west of it, is in some respects analogous to the
nal pressure of the Mississippi valley, which separates the
normal pressures of the Rocky Mountains and of the south
f the United States.

nfluence of land and water respectively in the cold season of
is well shown in fig. 16, which represents for every 0·020
e normal pressure over the British Islands in January,
from means calculated for two hundred and ninety-two
1

n the winter months that the isobars of the British Islands
most closely together, and in accordance therewith strong
re then most prevalent. The crowding of the isobars
the maximum in January, forming what is probably the
mean monthly barometric gradient that occurs at any
anywhere on the globe. The point however, to which
is here drawn is the remarkable influence of St George's
and the Irish Sea in diminishing the pressures as they
so seas, and of the land in increasing the pressure, which
n the curves occupying approximately the central districts

of Great Britain from the Isle of Wight to Cape Wrath,
shows on a comparatively small scale the influence of the

nths of the year, just as is seen on the grand scale in central
and the north of the Atlantic.

Journal of Scot. Meteorological Society, vol. vi. pp. 4–21.

Mean Atmospheric Pressure in July (fig. 17). In this
physical conditions are the reverse of what obtains in Jan
effects of the influence of the sun on the temperature and
of the atmosphere owing to the maximum in the northern

he minimum in the southern hemisphere. With the solar
ns reversed, a comparison of figs. 14 and 17 shows that the
tion of atmospheric pressure is duly considered on a broad
e reverse of what takes place in January.
he southern hemisphere atmospheric pressure during the
season is above the general average of 30 inche between
and 40° S. This belt of high pressure encircles the globe,
by four regions where the pressure is considerably above
eral hemispheric average. The first region is in South Africa, about
where it rises to a little above 30·5 inches; in Australia,
rises on the Murray to nearly to 30·40 inches;
h America, where on the La Plata, about lat. 30°,
to 30·1 inches, and it rises eastwards and westwards, where it
30·07 inches. The pressure is lowered with respect to the
of the three centres of high pressure at this season—that they
ce surface between 25° and 30°. A comparison
nearly, pressure is duly the whole of the broa
the southern hemisphere, about two-tenths of an inch
which is the amplitude of variation. A comparison of
and Java shows that the large accession to the pressure of
hemisphere is accompanied by an extraordinary d
of pressure over the continents of the northern hemisph
pressure during the winter
northern normal pressure occurs in the continent of Asia, the
diminution of pressure in the summer months takes place
continent. The positions, however, of the two extreme
on being, in the one region or even near each other. In
continent the maximum occurs in the valley of the upper
sia, at Nertchinsk, the normal pressure in January is
·500 inches, whereas the lowest normal pressure in July is
inches, and over as far as observations enable us to locate
obtained on the west side of the basin of the Indus. The
of these two normals is 1·55 inch; and over no inconsider
tion of central Asia the normal pressure of July is much
that of January. In other words, the influence of the sum
is exerted on the temperature and aqueous vapour of the
and atmospheric movements resulting therefrom is so
as to remove a thirtieth part of the whole mass of the
the extensive region.
The extension in recent years of good meteorological stations
Russian and Indian empires enables us to lay down with
greater precision than formerly the lines of pressure. Of the
indicated by the new isobars the most important perhaps
sence of the region of minimum pressure in Asia, which is
to occupy the basin of the Indus, and thence stretches
somewhat broad region to westward nearly as far as the basin
Caspian Sea. The point is of no small importance in atmo-
physics inasmuch as it places the region of least normal
in July as close geographically to the region where at the
mid-temperature is highest as the region of highest normal
in January is situated with respect to the region where in
both cases mid-temperature is lowest in Asia.
The colour of India are of special interest, and imply con
siderable practical advantage to the empire. From
southward the normal pressure is everywhere higher and
ably so, along the whole of the west than it is on the east
India—the difference being approximately half a tenth
inch. This is represented on the map by the slanting of the
from north-west to south-east as they cross this part of
and it is to be noted that the east and west coasts of Ceylon
the same kind of distribution of the pressure. The conse-
of this peculiarity in the distribution of the pressure is that
summer monsoon blows more directly from the ocean over
the southern India than would have been the case if the
had been even and west and thus probably precipitates in
greater abundance rainfall over this part of the empire.
same anomaly in the sequence follows from the geographical
tion of the pressure over the valley of the Ganges. If the
pressure there were diminished in the manner it does over
the south of the Ganges valley, the winds would have
south-westerly and the summer climate practically rainless.
however, is not the case, but the normal pressure diminishes
ds along the valley of the Ganges as the following mean
ssures will show: Calcutta, 29·576 inches; Patna, 29·535
Lucknow, 29·502 inches; Roorkee, 29·505 inches; and in
westward into the Punjab pressure falls still lower—to
nches at Mooltan and 29·442 inches at Jacobabad. Indeed
in July is 0·290 inches lower at Jacobabad than at Sibsagar
Brahmaputra, nearly in the same latitude. It necessarily
rom this distribution of the pressure that the summer mon
which blows northward over the Bay of Bengal, is deflected
E S E wind which fills the whole valley of the Ganges,
ing on its way a most generous rainfall over that magnifi
ion.
influence of the land in lowering the pressure in summer is
strated by the course of the isobars over western Siberia
sia, where pressure is seen to fall relatively lowest along
the middle line of the Old Continent. In this connexio
interesting to note the course of the isobar of 29·90 inc
that part of Europe where the breadth of the land is cons
increased—between the Baltic and Constantinople. In co
junction to this the influence of the Aral, Caspian, and Bla
in maintaining a higher pressure appears in the remarka
longation eastward of the isobars of higher pressure over th
of these seas, being in striking contrast to the lower pressure
prevail to the north and south.
The lowering of the normal pressure is very decided in th
regions of Spain, North Italy, and Scandinavia. The effect
strongly seen in Spain, the largest and compactest of these
Thus, while the normal pressure diminishes between Lisb
Barcelona from 30·086 to 30·018 inches, the sea-level pre
Madrid falls nearly to 30·000, and the pressure at Saragos
Valladolid is nearly a low. The lowering of the pressure
interior influence materially its summer climate. As rem
an illustration of the principle can be pointed to anywhere
in the north of Italy; for while the normal pressure at Mo
is 29·941 inches, at Genoa on the coast the relatively high
of 29·992 inches is maintained, the distance of the two place
about 40 miles. To the east pressure rises to 29·970 i
Venice, and to westward to 30·023 inches at Geneva. Over
navia, along the west coast from the Arctic circle southw
normal pressure equals or exceeds 29·80 inches, the variatio
comparatively small; and along the coast from the head of
of Bothnia to the south-east of Sweden pressure is also excee
inches, and the increase from north to south proceeds at a sl
In, however, the strictly inland districts to the north
Christiania, which lie immediately to the east of the Scand
, and sheltered by that lofty range from the wind
Atlantic, pr erably lower than it is along the
west coasts of the peninsula. Owing to this peculiar dist
of the pressure, the winds which necessarily result from i
much finer summer climate to the south-east of Norway an
strictly inland part of Sweden than would otherwise be the
The remarkable curving northward of the isobar of 29·8

the northerly winds that blow towards the low-pressure r
Central Asia, to the serious deterioration of the summer cl
northern Siberia, do not extend so far to westward as Lapl
The distribution of the normal pressure over North A
quite analogous to what prevails over Asia, but, the contine
less, the diminution of pressure in the interior is also cor
ingly less. The highest normal pressure, 30·077 inches, is
the south-east in Florida, and the lowest, 29·780 inches, in t
difference being thus 0·297 inch. Another region of relativ
pressure is in the north-western States and British Columb
north, the maximum, near the mouth of the Columbi
reaches 30·06 inches, being thus nearly as high as what
Florida. These two regions are merely extensions of in
high-pressure area which at this season are highly chara
feature of the meteorology of the North Pacific and North
respectively.
Of these two regions of high pressure the one overspread
Atlantic between the United States and Africa is the more
being not only the region where pressure is highest anyw
the globe during the months of June, July, and August, b
the normal pressure reaches the highest point attained at an
over the ocean. The highest point reached by the normal
over the land at any season occurs, as has been pointed out,
centre of Asia, or approximately in the middle region of th
continuous land surface on the globe during the coldest m
the year. On the other hand, the highest pressure over t
occurs during the warmest months of the year, and not
largest water surface, but in the middle regions of the North
where the breadth is only about half that of the water surfa
North Pacific.
From the essential differences between these two sets o
mena it may be inferred that the extraordinarily high
which is so marked a feature of the meteorology of Cent
during the cold months of the year is a direct consequenc
lowering of the temperature of the land of Asia and of th
sphere resting on it during the time of the year when the
solar radiation are at the annual minimum, and of terrestri
tion at the annual maximum. But the determination of t
and time of highest pressure over the ocean must be reg
indirectly brought about. The physical conditions under
occurs are these:—it happens (1) at the time of the year w
earth presents the largest surface of land to the sun, and
that part of the ocean which is most completely surrounded
highly heated land surfaces. This high summer pressure
Atlantic has its origin in the upper currents of the atmosph

Mean Atmospheric Pressure for the Year.—The distrib
annual atmospheric pressure may be considered as repr

s of the influences directly and indirectly at work throughout
in increasing or diminishing the pressure of the atmosphere
re two regions of high pressure, the one north and the
outh of the equator, which pass completely round the globe
belts of high pressure. The belt of high pressure in the
hemisphere lies nearly parallel to the equator, and is of
nuniform breadth throughout, but the belt north of the
has a very irregular outline and shows great diffe
lth and its inclination to the equator. These irregularities
depend on the peculiar distribution of land and water which
in the northern hemisphere.
two zones of high pressure enclose between them the com
ly low pressure of the tropics, through the centre of which
narrower belt of still lower pressure, towards which the trades
n either hand blow. Considered in a broad sense, there
y three regions of l qu one just
to, and one round ch pole bounded by or consisting
the zones of high pressure just described. The no
ble of these, so far as it is known, is the re
about the South pole which remains low throughout
aying the principal role in the wind systems of t Antarct
its heavy snowfall not rainfall, and in the enormous ice
hich form so striking a feature of the water of the Southern

epression around the north pole contains within its area two
centres of still lower pressure, the one filling the northern
he Atlantic and the other that of the Pacific. Of these two
pressure area round Iceland is the deeper and is probably
d by the steeper barometric gradients and stronger winds
revail over the North Atlantic. The broad equatorial zone
ressure also contains two distinct regions characterized by
ver pressures. The larger of the two stretches across
n Asia from Assam to head of Persian Gulf, and is
due to the very low pressures which form so marked a feature
mmer meteorology of that part of Asia. The regions of
he Indus and upper Ganges occupy a centre of this low
area, where normal press ort of 29·80 inches
ost area of lowest equatorial pressure is in the centre of

y be here pointed out that the whole of these areas of low
nnual pressure po ommon characteristic of
e amount of moisture in the atmosphere. The Arctic and
e zones of low pressure, and the equatorial low-pressure zone
y, may be regarded as all but wholly occupied by the com
ly large amount of vapour in their atmosphere. As regards
on of low pressure of southern Asia in summer, it is
ble that, while the eastern half which overspreads the valley
Ganges is characterized by a moist atmosphere and large
the western half of it is singularly dry and practically rain
l that the central portion of this remarkable depression
a region where at the time the climate is one of the driest
est anywhere to be found on the globe. Hence, while the
s the more important of the disturbing influences at work
mosphere, the temperature of space plays no inconspicuous part
in destroying atmospheric equilibrium, from which result
torms, and many other atmospheric chang

Prevailing Winds of the Globe. If atmospheric
e were equal in all parts of the earth we should
he physical conditions of a stagnant atmosphere.
owever, is not the case. Let there be produced a
ration of aqueous vapour over a particular region,
one region show a higher temperature than what
s around it, then from the different densities,
nsequently different pressures thereby produced,
uilibrium of the atmosphere is destroyed, and, as
be expected from the laws of aerial fluids, move-
of the air, or winds, set in to restore the equili-
Now every one of the isobaric maps we have
as well as every isobaric map which has been made
ecorded observations, indicates very considerable
ance of the equilibrium at the surface of the earth.
servation shows that the prevailing winds of any
at any season of the year are simply the expression
atmospheric movements which result from the dis
e of the equilibrium of the atmosphere indicated by
baric maps for that season and region.
winds may be regarded as caused directly by differences
ospheric pressure, just as the flow of rivers is caused
erences of level, the motion of the air and the motion
water being both referable to gravitation. The wind
from a region of higher towards a region of lower

pressure,—in other words from where there is a sur
where there is a deficiency of air; and this take
whether the differences of pressure be measurable
barometer, as is generally the case, or not readily
ible, as in se of sea breezes, squalls, and sudde
of wind which are of short duration.
So far as is known, differences of atmospheric p
and consequently all winds, originate in changes of
either in the temperature or the humidity of the
restricted regions. Thus, if two regions contiguous
other come to be of unequal temperature, the air
warmer region, being specifically lighter, will ascen
the heavier air of the colder region will flow in b
take its place. Of this class of winds the sea an
breezes are the best examples. Again, if the air
region comes to be more highly charged with
vapour than the air of surrounding regions, the air
more humid region being lighter will ascend, wh
heavier air of the drier regions will flow in bel
take its place. Since part of the vapour will be con
into cloud or rain as it ascends, heat is thereby disen
and the equilibrium still further disturbed. In th
originate gales, storms, tempests, hurricanes, and
more violent commotions of the atmosphere, except
of the form of the whirlwind, such as dust storms,
production of which very great differences of temp
are more immediately and exclusively concerned.
The Trade Winds. From fig. 11, giving the is
for January, it is seen that atmospheric pressure
Atlantic is lower near the equator than it is to
and south of it, and the arrows indicate that to th
of the tract of lowest pressure N.E. winds prev
to the south of it S.E. winds. These are th
known N.E. and S.E. trade winds, which thus blo
regions of high pressure towards the tract of lower p
situated midway between them. The trade winds
blow directly to where the lowest pressure is, but in
ing direction at an angle of about half a degree. The
tion from the direct course is due to the influence
rotation of the earth on its axis from west to ea
influence to which all winds and all currents of th
are subject.
In virtue of this rotation, objects on the earth's
at the equator are carried round toward the east
rate of about 17 miles a minute. On receding fr
equator, however, this rate of velocity is being cont
diminished, so that at 60° N. lat. it is only about S
a minute, and at the pole nothing. From this it
that a wind blowing along the earth's surface in th
tion of the equator is constantly arriving at places
have a greater eastward velocity than itself. A
thus lags behind, these places come up, as it were,
it, the result being an east wind. Since, therefo
wind north of the equator is under the influence
forces, one, the low pressure near the equator,
it southwards, and the other, the rotation of the
deflecting it eastwards, it will, by the law of the c
tion of forces, take an intermediate direction, and blo
north-east. For the same reason, south of the equ
south is deflected into a south-east wind.
In the Atlantic the north trades prevail
latitudes 7° and 30° N., and the south trades betwe
tudes 3° N. and 25° S. These limits are not stat
but follow the sun, being farthest to the
and to the north in August. The tract of low p
between these wind systems is named the region of
owing to the calm weather which often prevails the
it is also characterized by the frequent occurrence o
rains. This region of calms varies its position wi
of the sun, reaching its most northern limit, lat.

gust, and its most southern, lat. 1° N., in February. eadth varies from 3° to 8°, and it lies generally l to the equator. It is to be noted that, in the ic, the region of calms is at all seasons north of the r.

th and south trades also prevail in the Pacific Ocean, ted by a region of calms, which would appear, how o be of less breadth and to be less clearly defined s the region of calms in the Atlantic. In the eastern n of the Pacific the region of calms lies at all seasons north of the equator, but in the western division it nsiderably south of the equator during the summer s of the southern hemisphere, this southerly position n all likelihood occasioned by the extraordinarily high re in Asia in its relations to the low pressure in the or of Australia at the season. During the summer s of the northern hemisphere the region of calms disappears from the Indian Ocean and from the n part of the Pacific Ocean, there being then an ken diminishing pressure from the latitude of ms and Central Australia northwards as far as the e are of Central Asia

gion of light and variable winds and calms occur at ghest limits of the north and south trades. Except in cific, where, owing to the greater breadth of that they spread over a considerable extent, these regions but in circumscribed patches, such as characterize eteorology of the North and South Atlantic about les 26° to 36°. Of these regions of calms the most tant is that marked off by the high pressure in the Atlantic, between the United States and Africa the region of the Sargasso Sea, where the weather acterized by calms and variable winds, and the ocean comparatively still waters. These are known to n as the "horse latitudes," and are essentially nt from the equatorial region of calms. The latter, been stated, is the region of low pressure at the ge of the north and south trades, where the climate tinguished for its general sunlessness and heavy ll. On the other hand, the calm regions in the ic and Pacific Oceans about the tropics have an spheric pressure abnormally high, clear skies, and eather generally sunny and bright, with occasional s.

merous observations made in all parts of the globe ish the fact that, while the surface winds within the are directed towards the equatorial region of calms h a manner that the general intertropical movement atmosphere or prevailing winds are easterly, the ding winds of the north and south temperate zones esterly. The veering of these great aerial currents to the same cause that gives easting to the trade- viz. the rotation of the earth round its axis. For, aerial current advances into higher latitudes, it is ually arrives at regions having a less rotatory velocity it-self, it thus outstrips them and leaves them behind, her words, it blows over these places as a westerly

hile, however, the general prevalence of westerly winds been established over the extratropical regions of e, Asia, Africa, America, and Australia, the direc- which in different seasons and at different places are lly found to prevail often differ very widely from An examination of the winds at one hundred and places pretty well distributed over the northern sphere reveals the instructive fact that almost every shows two maximum directions from which winds more frequently than from the other directions, and ne of these two directions shows a considerable excess he other. Thus, for example, the following are, on a twenty years' average, the number of days at Gree each wind prevails during the year: N., 41; N.E., 4 23, S.E., 21; S., 34; S.W., 103; W., 38; N.W., 2 calms, 32. Hence S.W. and N.E. winds are there prevalent than winds from any other direction, and of two winds the greater maximum direction is S.W. two maximum directions be sorted into groups, the greater maximum direction occurs as follows:

from S.S.W.	to W.	at	47	places
,, W.N.W.	,, N.	,,	33	,,
,, N.N.E.	,, E.	,,	19	,,
,, E.S.E.	,, S.	,,	16	,,

and the other maximum direction is

from S.S.W.	to W.	at	20	places
,, W.N.W.	,, N.	,,	22	,,
,, N.N.E.	,, E.	,,	38	,,
,, E.S.E.	,, S.	,,	32	,,

This result of observation, so different from what wa accepted as being in accordance with the generally re theory of the movements of the atmosphere, teach important lesson that the region towards which the tropical winds of the northern hemisphere are dire not the region of the north pole.

Prevailing Winds in January.—On examining which shows the distribution of atmospheric press January, it is seen that pressure is abnormally lo the northern portion of the Atlantic—the lowest oc between Iceland and South Greenland—from wh rises as we proceed in a S.W. direction towards A in a S. direction over the Atlantic, and in a S.E. direction over Europe and Asia. Now what influe this remarkable atmospheric depression on the pre winds over this large and important part of the surface? The arrows in the figure, which indica prevailing winds, and which have been laid dow observations, answer this question.

At stations on the east side of North Ameri arrows show a decided predominance of north-west at the more northern places the general direction i northerly, whereas farther south it is more westerl the Atlantic between America and Great Britain, south of England, in France and Belgium, the direc nearly S.W. In Ireland and Scotland it is W in Denmark and the north-west of Russia S.S.W. St Petersburg to Tobolsk S.W.; on the west of E generally S.S.E.; and in Greenland, the north of I and about Spitzbergen N.E. Hence all the pre winds in January over this extensive portion of th may be regarded as the simple expression of the di of atmospheric pressure which prevails over the d parts of the region. In truth the whole appears vortices, or in an in-moving spiral course, towa region of low pressure lying to the south west of I and extending eastward over the Arctic Sea north of The only marked changes in these directions of th thus broadly sketched out are the deflexions by the various mountain systems which lie, so to embedded in these vast aerial currents; of the winds in the south of Norway afford excellent i tions.

The influence which this peculiar distribution pressure over the north of the Atlantic exerc absolutely determining the winter climates of the re countries is most instructive. It is to this low p which draws over the British Islands W.S.W. from the warm waters of the Atlantic, that the ope and, it must be added, rainy winters of these isla due. The same region of low pressure gives Rus Western Siberia their severe winters; and it is th consideration that fully explains the enormous defl the isothermal lines from Norway eastwards and

rds over the Old Continent. Finally, the same low
e draws over British America and the United States,
N.W. winds which it induces, the intensely dry
-current of the Arctic regions. At Portland, Maine,
is swept by these cold north-westerly winds, the
temperature in January is 23°6, whereas at
a, on the coast of Spain, in nearly the same latitude,
south westerly winds from the Atlantic prevail, the
emperature of the month is 49°1, or 25°5 higher.
region of low atmospheric pressure in the north of
cific is accompanied by prevailing winds over the
mbraced by it and by climatic effects in all respects
to the above. In Vancouver Island the prevailing
in January are S.W., at Sitka E.S.E., on Great
ake E.N.E., in Alaska N.E., in Kamchatka N.N.E.,
Japan N.W. In accordance with these winds
nter climate of Vancouver and adjoining regions
and humid, and that of the north-east of Asia dry
ensely cold.

he other hand, abnormally high pressure rules over
tinent of Asia at this season, and as regards this
of high pressure the arrows represent the winds as
g outwards from it in all directions. Over the
of Asia, where the highest normal pressures are,
ations show a marked prevalence of calms and light
but around this central region the prevailing winds
uary are—at Calcutta N., at Hong Kong E.N.E.,
ing N.W., on the Amur W.N.W., S.E. at Nijni-
k and S.S.W. at Ustjansk (in the north of Siberia),
Bogoslovsk S.W. Hence from this extensive
where pressure is abnormally high, or where at
ason there is a large surplus of air, the prevailing
flow outwards in all directions towards the lower
e which surrounds it. Owing to the excessive dry
the air of Central Asia, terrestrial radiation is less
ted there than anywhere else on the globe, and
uently the temperature falls very low, the mean of
y at Werchojansk being −55°8, which is the lowest
monthly temperature known to occur on the earth's
. And, since the winds blow outwards from the
d climates of the interior, temperatures are low,
the coasts. Of this China affords good illustrations.
he mean January temperature of Peking is 22°7 and
a Wei, near Shanghai, 35°1, whereas at Corfu and
dria the normal temperatures for January are
ively 50°9 and 58°0, or 28°2 and 22°6 higher
corresponding latitudes on the coast of China.
winds of the United States in winter, taken in
ion with the peculiar distribution of pressure already
ed, are very interesting. There are two regions of
ressure, one in the south-eastern States and the other
rger one in the region around Utah; and between
here is interposed a trough of lower pressure extend
om Chicago to the south-west of Texas. On the
n side of this depression the winds are north
y, but to the east of it they become W., W.S.W.,
some places S.W., and again on nearing the Atlantic
d they become north westerly. In connexion with
gion of higher pressure in the west, the prevailing
are seen to flow outward from it. The normal
e diminishes everywhere to southward of a line
from the Canaries to Bermuda, thence westward in
the same latitude to Texas, and then to west north-
o San Francisco. The tract of lowest pressure
es from the basin of the Amazon in the direction of
mus of Panama in about latitude 8° N., and thence
inued westward for a considerable distance into the
in nearly the same latitude. It follows from this
ution of the pressure that the north trades in a more
modified form prevail over South America to the
north of the Amazon, and in the Pacific to the n
lat. 8° N., probably as far to westward as long. 150

The low pressure systems which prevail durin
summer months in South America and South Afric
each its corresponding system of winds all round
however, in Australia, as being the most compa
isolated continent, that the influence of the summer
lowering the pressure is best illustrated. In that co
the lowest pressure occurs in the region situated
midway between the north coast and the tro
Capricorn, over which the normal pressure does not
29·80 inches. Further, everywhere in Australia p
diminishes from the coast on advancing upon the
districts. It follows from this disposition of the p
that all round the island the prevailing winds in s
blow from the sea towards the interior; and accordi
is in these months that the greater part of the rai
From the low pressure of the interior southwards to
Straits pressure rises continuously, the increase
normal over this space being about 0·200 inch. To
ward it also rises continuously to beyond the no
China, the increase on this side being about ¾ of a
In this case the greater part of the increase occu
the continent, the rate of increase from the n
Australia to the Philippine Island being only abo
rate of increase which obtains southward towards
Straits. It will be shown when the subject of the
is examined that it is the relative excess of thes
pressures, the one in the south of Australia and th
in the south-east of Asia, that determines the p
of the area of low pressure in Australia in particular
and with that position the degree and extent to wh
whole of the northern portion of Australia is wate
the rainfall. Thus, when pressure is more than
high in the south-east of Asia, and either low or
cessive in the south of Australia, then the low p
region is pushed farther southward into the intern
with it the rainfall spreads inland over a wider area
a greater depth.

Prevailing Winds in July. In the winter
southern hemisphere, the geographical distribut
pressure is exactly the reverse in Australia of what
during the summer months. Everywhere all ro
increases on advancing from the coast into inland d
The lowest pressure, about 30·00 inches, occurs
north coast, and the highest over the basin of the
river and its affluents, where it rises generally to
inches. On the south coast it is generally about
inches, falling, however, at Cabo Island, in the e
south-east, to 30·050 inches, and to 29·836 in the s
New Zealand. From the Murray river the diminu
pressure is continuous to the north, even to the low p
of Central Asia. From the arrangement of the p
the prevailing winds blow from the interior towa
surrounding ocean all round Australia, with the
exception of the extreme south-west of the continent
the prevailing winds are south-westerly, being here
ally an outflow of the high pressure which overspre
Indian Ocean to the westward. As these S.W. wi
from the ocean, the rainfall at Perth in July is
inches, and it is high over south-western districts o
Australia. The prevailing winds round Australia
on the north coast, S.W. at Brisbane, W.N.W. at S
N. at Melbourne, N.E. at Adelaide. These all re
an outflow from the high-pressure region of the
modified by the influence of the earth's rotation,
correspondence with the reversal of the distribution
pressure, are directions the reverse of the prevailing
of January.

In July the central and southern parts of A

heated by the summer sun, and, besides, the rainfall uthern parts is excessive. Consequently atmospheric is very low, being fully 0·10 inch lower in the than it is in the south of Ceylon. From the pressure rises continuously on advancing to the d, southward, westward, and northward, and from directions the prevailing winds of summer flow upon the interior, and there bring rain or parching according to they have come from the they have traversed, and according as they advance warmer or colder regions. The prevailing of Asia, being an inflow upon the interior, general, by the reversal in direction of prevailing winds

wind of Europe are mainly determined by the dinarily high pressure of the Atlantic with its relations low pressure of Central Asia and Central at the time. The winds in the Spanish Peninsula th w to the north of Africa they are northerly, ion northwesterly in Syria. The winds of the Island and western Europe have long and orthern than the prevailing winds of winter, and to t to they become ideally north west. he Atlantic origin of these winds that the summer

ely large rainfall of this season, it being at this time e rainfall reaches the annual maximum. The bear the low pressure areas and mountain systems of the of Italy and Scandinavia on the climates of these will be afterwards referred to.

centre of lowest pressure in North America is over rict about Utah, from which it rises all round, but ward and most in south easterly and north westerly ons. In California N.W. winds necessarily blow in pon this central low pressure area, and, as these winds cessively over regions the temperature of which con increases, the summer climate is rainless. On the nd, southerly and south easterly winds from the Gulf o blow up the western side of the basin of the Mis ward upon the low pressure area of the centre de e in their course, are rainfall more or less abundant, ture they have brought from the Gulf. To the north ion, and to westward of Hudson's Bay, the prevail ds become easterly and north easterly, distributing Manitoba, Saskatchewan, and neighbouring regions, continue their westerly course towards the low e area, the rainfall they have transported thither

he wide expanse of Hudson's Bay. An attentive ation of the arrow of fig. 17 shows that the prevail ol over all the States to the east of the Mississippi r rather to be regarded as an outflow from the of very high pressure over the Atlantic to south d. Thus in Florida the winds are S.E., in the te States S., and in the lake region, in the New Eng ates, and on the Atlantic seaboard S.W. Since the of these winds is thus essentially oceanic, and since r course northwards no mountain range crosses their he whole of the extensive region enjoys a large but mean excessive rainfall, which, taken in connexion he temperature, renders the summer climate of these one of the best to be met with anywhere on obe for the successful prosecution of agricultural ries.

remarkable protrusion of high pressures from the rn hemisphere, where they are massed at this time year, northwards into the Atlantic is, as has already eferred to, one of the outstanding features of the ology of the summer months of the northern hemi-

In the central area of this large region the climate rkable for its prevailing calms, light winds, occasional squalls, and clear skies. From this comparatively space the wind blows outwards in all directions towards in upon the surrounding regions of low pressure. T winds, owing to the high temperature, clear skies, and st sunshine of the region from which they issue, carry them a great amount of vapour near the surface, by w to a large extent the north of South America, the ea North America, the greater part of Europe, and a large tion of Africa are watered. The prevailing winds over region are further interesting, not merely from the str illustration they give of the intimate relation of the w to the distribution of the pressure, but as being of no importance in determining the best routes to be taken this great highway of commerce, and the more so inasm as the currents of the ocean are coincident with these vailing winds.

In the Antarctic regions, or rather to the south of 15° S., the normal atmospheric pressure is low a season, there being a gradual diminution of pressu 29·20 inches about lat. 60° S. Pressure is probably still lower nearer to the south pole, as seems to be cated by the observations made by Sir James C. Ross in the "Challenger" and other expeditions. Over zone the prevailing winds are W.N.W. and N.W. T the region of the "brave west winds," the "roaring for of sailors, which play such an important part in naviga and which determine that the outward voyage to Aust be round the Cape of Good Hope and thence eastward the homeward voyage eastward round Cape Horn globe being thus circumnavigated by the double vo That the general drift of these winds is inwards upo south pole is strongly attested by the existence of enormously thick wall of ice which engirdles these reg from which are constantly breaking away the innume icebergs that cover the Southern Ocean, none of wh ever seen of a calculated thickness less than 1400 The snow and rainfall which must take place in the polar regions for the formation of icebergs of su thickness must be peculiarly heavy, but not heavier might be expected from the strength and degree of sa tion of the "roaring forties" which unceasingly precip their moisture over these regions.

To sum up, so far as the prevailing winds are cerned, it has been shown that where pressure is high i.e. to say, where there exists a surplus of air, out of a region winds blow in all directions; and, on the hand, where pressure is low, or where there is a defic of air, towards such a region winds blow from all direc in an in moving spiral course. This outflow of air-cu from a region of high pressure upon a region of low sure is reducible to a single principle, viz., the princi gravitation. Given as observed facts the differenc pressure, it is easy to state with a close approximati accuracy what are the prevailing winds, before calcul the averages from the wind observations. Indeed so dominating is the influence of gravitation where differ of pressure, however produced, exist that it may practi be regarded as the sole force immediately concerne cerning the movements of the atmosphere. If the any other force or forces that set the winds in m independently of the force called into play by differen mass or pressure, their influence must be altogether nificant as compared with gravitation.

It has been abundantly proved that the wind doe blow directly from the region of high towards that o pressure, but that, in the northern hemisphere, the regi lowest pressure is to the left of the direction towards the wind blows, and in the southern hemisphere to right of it. This direction of the prevailing wind reference to the pressure is in strict accordance with

s Law of the Winds, which may be thus expressed:—
nd neither blows round the centre of lowest pressure
les, or as tangents to the concentric isobaric curves
ms or cyclones, nor does it blow directly towards the
; but it takes a direction intermediate, approaching,
er, more nearly to the direction and course of the
r curves than of the radii to the centre. The angle
by a line drawn to the centre of lowest pressure
he observer's position and a line drawn in the direc
the wind is not a right angle, but an angle of from
80°.

n its importance in practical meteorology Buy
s law may be stated in these two convenient form
nd with your back to the wind, and the centre of
pression or the place where the barometer is lowest
to your left in the northern hemisphere, and to
ght in the southern hemisphere. This is the rule
ors by which they are guided to veer with retar-
storms. (2) Stand with the high barometer to
ght and the low barometer to your left, and the
ill blow on your back, these positions in the southern
here being reversed. It is in this form that the
ing winds of any part of the globe may be worked
m the isobaric charts (figs. 14 and 17).

n the all-important consequence which flow from the
bhical distribution of the pressure it is evident that
ions of low and of high normal pressure must be
d as the true poles of the prevailing winds on the
surface, towards which and from which the great
ents of the atmosphere proceed. From the unequal
ution of land and water, and their different relations
and terrestrial radiation, it follows that the poles
ssure and of atmospheric movements are, just as
s with respect to the poles of temperature, very far
ing coincident with the north pole. Thus during
ter months the regions to which the origin of the
revailing winds of the northern hemisphere are to
erred are Central Asia, the region of the Rocky
ins, and the horse latitudes of the Atlantic, and
ions towards and in upon which they flow are the
ssure systems in the north of the Atlantic and
Oceans, and the tract of low pressure within the
towards which the trade-winds blow. In the
r months the reversed conditions of pressure distri-
then observed are attended with corresponding
s in the prevailing winds, and, generally speaking,
outh polar region be excepted, the poles of highest
vest pressure and atmospheric movements are at no
incident with the north pole. It is this considera
hich affords the true explanation why prevailing
t so large a proportion of stations in the northern
here do not blow in the directions in which true
rial and polar winds should blow.

causes which bring about an unequal distribution of
ss of the earth's atmosphere are mainly these two -
perature and the moisture of the atmosphere con
with respect to the geographical distribution of
d water. Owing to the very different relations of
nd water to temperature, as already stated, the
r temperature of continents greatly exceeds that of
an in the same latitudes. Hence the abnormally
emperature which prevails in the interior of Asia,
America, and Australia during their respective
rs, in consequence of which the air, becoming speci-
lighter, ascends in enormous columns thousands of
diameter. *On arriving at the higher regions of*
nosphere it flows over neighbouring regions where
face temperature is lower, and thus the atmospheric
e of the highly heated regions is diminished.
ace winds set in all round to take the place of the
air removed from the continents by these asc
currents, and since these necessarily are chiefly wa
the ocean they are highly charged with aqueous
by the presence of which, and by the condensation
vapour into cloud and rain, the pressure over conti
this season is still further and very largely dim
An charged with vapour is specifically lighter tha
without the vapour, in other words, the more
any given quantity of atmospheric air has in it t
is its specific gravity; and, further, the conde
of vapour in ascending air is the chief cause of the
effect being so much less than that which wo
experienced by dry air. From these two pri
which were established by Dalton, Joule, and Sir W
Thomson, it follows that the pressure of vapour in
and its condensation, exercise a powerful influe
diminishing the pressure. The great disturbing inf
at work in the atmosphere are the forces called in
by its aqueous vapour; and it is to these, co-operatin
the forces called into play by the differences of temp
directly, that the low normal pressure of the con
during the summer is to be ascribed. The degree to
the lowering of the pressure takes place is, as was t
been expected, greatest in Asia, the largest continen
least in Australia, the smallest continent, while in A
it is intermediate.

The influence of the aqueous vapour in diminish
pressure is well seen in the belt of calms in the
between the north and the south trade winds. Sinc
winds import into the belt of calms the vapour the
taken up from the sea on their way thither, the cli
characterized by a highly saturated atmosphere and
rains. Again the air in regions near the Atlantic c
much more vapour and is of a higher temperature
winter than is observed at places in the interior
tinents in the same latitudes. It follows thus that
over the north of the Atlantic and the regions adjoi
specifically lighter than in the regions which su
them. We have here therefore the physical condit
an ascending current; and it is plain that the stre
this current will not merely be kept up but increa
the condensations of the vapour into cloud and rain
take place within it by which a higher temperature
greater specific lightness are maintained at the su
the earth and at various heights in the atmospher
exist over surrounding regions at the same l
Accordingly it is seen from the winter isobars t
enormous diminution of pressure occurs over these
and also over the north of the Pacific and the An
as compared with the continents.

Since, on the other hand, dry and cold air is spec
heavy, the winter isobars show that where tempera
low and the air very dry pressure is high. Of th
and North America are striking examples during De
January, and February, and Australia, South Afri
South America during June, July, and August.

Since vast volume of air are thus poured into the
where pressure is low without increasing that press
vast volumes flow out of the region where pressure
without diminishing that pressure, it necessarily
that the volumes of air poured into the region
normal pressure do not accumulate over that reg
must somehow escape away into other regions, a
the volumes of air which flow out from the region
normal pressure must have their place supplied b
accessions of air poured in from above. That th
law of relation observed between sea-level pressu
surface winds obtains between pressures at different
and winds at the same heights is simply a ne
inference. We are therefore justified in expecti

ng currents will continue their ascent till a height
ned at which the pressure of the air composing the
s equals or just falls short of the pressure over the
nding regions at that high level. On reaching this
the air, no longer buoyed up by a greater specific
than that of the surrounding air, will cease to
, and expanding horizontally will thenceforth flow
an upper current towards those regions which offer
st resistance to its course, that is to say, it will
er upon those regions where, at that height, pressure
s at the time to be least. Now from the known
es of air of different temperatures and humidities it
nt that the overflow of the upper current will take
owards and over that region or regions the air of
n the lower strata of the atmosphere happens to be
and drier than that of the other surrounding
s, because, being denser, a greater mass of air is
sed or gathered together in the lower strata of the
here, thus leaving a less mass of air, or a diminished
e, in the higher region of the upper current.
n be so, then the extraordinarily high pressure of
Asia during winter is to be ascribed to these two
(1) the low temperature and excessive dryness of
at this extensive region; and (2) its relative
ity to the low pressure of the Atlantic to the north
e low pressure of the Pacific to the north-east, and
pressure of the belt of calms to the south.
ly, since in summer the temperature of air resting
e Atlantic between Africa and the United States
ower than that of the land, the ascending currents
rise from the heated lands of Africa, Europe, and
and South America, as well as from the region of
mmediately to the south, all of which are remark
a low normal pressure, will on reaching the upper
of the atmosphere flow towards this part of the
, because there, the temperature being lower and
ity of the air composing the lower strata being
pressure in the upper regions is less. And, since
face winds are constantly flowing outwards from
gion of abnormally high pressure, thus draining
e air poured down upon it by the upper currents
converge upon it, extreme saturation does not take
and the air consequently is relatively dry and cool

researches into the upper currents of the atmosphere
n observations of the cirrus cloud
these considerations it may be concluded that the
which prevail near the earth's surface are known
he isobaric lines, the direction of the wind being
ross where pressure is high towards regions where
s in accordance with Buys Ballot's law; and that
per current may be inferred from the isobaric lines
reversely, together with the isothermal lines taken
. In other words, the regions of lowest pressure,
ern cyclonic circuit, and relatively higher pressure
t height as compared with surrounding regions,
ut the source or fountain-head from which the upper
s flow; and the isothermal, by showing where on
of the relatively low temperatures the greater
f the air is condensed in the lower strata of the
here and sea-level pressure consequently is high,
minishing the pressure of the upper regions, point
e regions towards and upon which the upper
s of the atmosphere flow. The facts of the diurnal
ons of the barometer in the different regions
discussed afford the strongest corroboration of these

tern "monsoon" has long been applied to the pre-

vailing winds in southern Asia which blow approx
from S.W. from April to October, and from N.E
November to April. The term is now, however, ge
applied to those winds connected with continents
are of seasonal occurrence, or which occur regular
the periodical return of the season. Since they are
immediately by the different temperatures and pr
which form marked features of the climates of co
in winter and summer respectively, they are mos
developed round the coast of Asia, owing to the
extent of that continent. The monsoons of differen
of the coasts of Asia differ widely in direction fro
other. Thus in winter and summer respectively t
W.N.W. and E.N.E. at the mouth of the Amur,
S.S.E. at Shanghai, N.E. and S.W. at Rangoon,
W.S.W. at Bombay, N.W. and S.W. at Jerusale
S.S.W. and N.N.E. at Archangel. The Indian
monsoon generally begins to break up in March, b
not till about the middle of May, when the norma
sure has been decidedly diminished over the
nterior, that the summer monsoon acquires its full s
and the heavy monsoonal rains fairly set in. In C
when the temperature has fallen considerably an
the falling temperature the pressure of the interior ha
the summer monsoon begins to break up, and this
is marked by variable winds, calms, and dest
hurricanes. As the temperature continues to fa
pressure to rise, the winter monsoon again resu
sway. Monsoons, equally with the trade-winds,
most important part in the economy of the globe
relatively great force and steadiness in the direc
which they blow, and the periodical change in thei
tion, give facility of intercourse between different co
and, besides, by the rainfall they bring they spread
over extensive regions which otherwise would be
wastes.

The winds of Australia are also strictly monsoo
owing to the small extent of that continent, and
quently the smaller differences there are betwe
normal pressure of the interior and that of the surro
coasts in summer and winter respectively, they a
strongly marked than are the monsoons of southern
and particularly they neither blow with the same fo
so steadily from the same point of the compass.
same reason the Australian climates are character
the occurrence of more frequent droughts than
climates of southern Asia, and the same remark ap
the climates of southern Africa.

Since the Malay archipelago lies during the sum
the northern hemisphere between the high pres
central Australia and the low pressure of Asia, and
the winter between the high pressure of Asia and
pressure of central Australia, it follows that the w
these islands are eminently monsoonal in their cha
being in summer southerly and in winter northerly
result of this peculiar wind system of the archipela
give to these islands a singular diversity of climates
will be more particularly referred to under rainfall.

At Zanzibar the prevailing wind in July is S.E.,
January, when the low pressure of the interior is s
much farther to southward, it is N.E.: and th
influence is felt, though in a greatly modified de
far as Mauritius, where the S.E. trade changes nea
E. during the summer. On the other side of Afr
S.E. trade of the South Atlantic is changed into
monsoon on the coast of the Gulf of Guinea."

In the southern, central, western, and northern
of North America the prevailing winds have a well-
monsoonal character. The prevailing winds of win
summer respectively are N.E. and S.S.E. at New O

and S.W. in Utah, N. and S. at Fort Yuma rnia), E.S.E. and N.W. at Portland (Oregon), and E.N.E. at Fort York, Hudson Bay. These winds dily accounted for by the distribution of pressure e continent in winter and summer. On the Atlantic rd of the United States the prevailing winds of vary from N.W. in the New England States to W. h Carolina; whereas in summer they vary generally .S.W. in South Carolina to S.W. in the New Eng ates. Hence over the eastern States the summer are not directed towards the low pressure region of erior of the continent, but are determined by the s of their pressure to the high pressure of the e to the eastward, and to the lower pressure overng the Atlantic to the N.E. This influence of the e may be considered as felt westward through the as far as the Mississippi.

gh not so decidedly marked, the winds of Europe, the extreme south, are also monsoonal In winter ow from the land towards the region of low pressure north of the Atlantic; but in summer the arrows, nting the prevailing winds, show that all but the exouth of Europe is swept by westerly winds, which flow st continuous stream from the Atlantic towards the regions of the Old Continent, and which deposit in ourse the rains they have brought from the ocean.

larly, monsoons prevail on the coasts of Brazil, North Africa, and many other regions which happen between other regions whose temperatures, and re pressures, differ markedly from each other at t times of the year.

e are the chief prevailing winds of the globe when erences of the normal atmospheric pressure are such ause a decided and steady movement of the atmoover a large portion of the earth's surface, resulting l-marked prevailing winds. But there are other which are greatly influenced by local causes, such as ure of the ground, whether covered with vegetation ; the physical configuration of the surface, whether mountainous; and the vicinity of extensive sheets h or salt water. An important characteristic of in their practical relations to climate is their ,—they being warm or cold, dry or moist, according r direction and the nature of the earth's surface nich they have just passed. Thus in the northern here southerly winds are warm and moist, while ly winds are cold and dry. In Europe south y winds are moist and easterly winds dry, while in w England States and Canada north easterly winds l and raw and north-westerly winds cold and dry.

articular regions certain meteorological conditions t stated seasons intensifying these effects, resulting ssive drought, heavy rains, intense or great heat, ving rise to the following among other well known

The east winds of the British Islands occur chiefly g, but also in a less degree in November, being in ter case often accompanied with fog. The winds ferred to are dry and parching, and their deleterious e on the health is seen, not merely in the discomfort easiness they impart to the less robust of the popu but also in the largely increased mortality which ause from consumption and all other diseases more connected with the nervous system. In the es bordering on the north of the Atlantic, atmopressure reaches the annual maximum in May, and ove the average during the other two spring months. se months the normal pressure approaches nearer to btains farther south, and an examination of daily r maps shows that this is due to the repeated nce in spring of very high pressures in the north of Europe while pressures much lower prevail to sout Now these east winds are simply the outflow fro regions of high pressure to northward. Northerly a westerly winds which are truly outflows from what styled Arctic anticyclonic areas bring with them qua noxious as those of the east wind itself, and prove a ous to health and vegetation. The cold dry wind o 29, 1868, which blasted and shrivelled up vegetation land, particularly in the western counties, as effect if a scorching fire had passed across them, was a wes

In the south of Europe, during the winter and early peculiarly dry, cold, and violent northerly winds are of oc occurrence Of these winds the "mistral" is one of t notorious, which is a steady violent, and cold north w blowing from central and eastern France down on the Lyons It is particularly trying while it lasts to invalids spending the winter at the various popular sanataria w scattered along this part of the Mediterranean coast. Th cold that took place in the north of Italy and south of Fr the beginning of 1868 was a good example of the mistra meteorological conditions under which it occurred were m low pressure over the Mediterranean to southward (29·150 whilst at the same time pressure rose steadily and rapidly ceeding northward to 30·905 inches in the north of Russia. this geographical distribution of the pressure, northerly win southwards over Europe, carrying with them the low temp of the higher latitudes, and became still colder and drier on the Alps before they made the descent on the shores of the M ranean The cold tempestuous winds which descend from th Alps and sweep over the Adriatic and the dreaded "greg Malta, which is a dry cold north east wind, are in their c and origin quite analogous to the mistral

The "northers," or "nortes," are peculiarly dry cold stron which repeatedly occur from September to March in the bordering on the Gulf of Mexico, and are perfectly analogou mistral The condition under which they occur are a lower than usual to the south or south east over the Gulf of together with a pressure even higher than the high norma is so marked a feature of the meteorology of the Rocky Mo during the colder months When, as most frequently h they occur in the wake of a storm, their disagreeable qua extreme dryness, cold, and violence are all intensified temperature of upwards of 80 experienced as the storm c the thermometer rapidly falls to 18 or even lower; and, as temperature often occurs with a wind blowing with great v the northers prove most deleterious A violent wind with perature of 18 is altogether unknown in the British Island

The "pampero" is a strong, dry cold wind which blows ac pampas of the River Plate of South America, occurring at all but most frequently during the spring and summer from Oc January. They are preceded by easterly winds, a falling p a rising temperature, and increased moisture. A pampe scribed by Dr D Christison and it appearance figured, *Journal of the Scottish Meteorological Society*, vol. v p. 342, advancing on the morning of November 28, 1867, in Uruguay In the early morning the wind blew rather from north east, and by and by cloud were seen movi slowly from the west, throwing out long streamers eastwar they advanced, two dense and perfectly regular clouds appeared in front, one behind the other, in close contact intermingling, the one being of a uniform leaden grey, w other was as black as the smoke of a steamer On arrivi head, the front, though slightly wavy in appearance, was se quite straight in its general direction, and the bands were of breadth They rushed forward at great speed under th clouds without uniting with them, preserving their forms su being borne onward by an apparently irresistible force, as posed of some solid material rather than vapour They probably 50 miles in length, but as they took only a few to pass their breadth was not great, and they appeared to to mere lines in the distant horizon At the instant the fir band arrived overhead, the wind chopped round from nort north and then to south west: a strong cold blast at the s seemed to fall from the leaden cloud, and continued to both bands had passed. No rain or thunder occurred at th but in the confused rabble of cloud, which followed fow continued to roll, and in a quarter of an hour rain fell, and hours thereafter wind, rain, and thunder continued, but o moderate degree. The low temperature and in the barom change of wind are the constant and most striking charac of the pampero. On one occasion the temperature fell 44 teen hours, and on another occasion the fall was only 4° a usual accompaniment, but on rare occasions the pampero and no rain falls.

fall.—Whatever tends to lower the temperature of below the dew point is a cause of rain. It is there- the winds we must chiefly look for an explanation rainfall, and the broad principles of the connexion stated to be these five. (1) when the winds have ly traversed a considerable extent of ocean, the is moderately large, (2) if the winds advance at me time into colder regions the rainfall is largely d, because the temperature is soon reduced below nt of saturation, (3) if the winds, though arriving he ocean, have not traversed a considerable extent of rainfall is not large, (4) if the winds, even though traversed a large extent of ocean, yet on arriving land proceed into lower latitudes or regions markedly r, the rainfall is small or nil, (5) if a range of ain, lies across the onward path of the winds, the l is largely increased on the side facing the winds, duced over the regions on the other side of the The reason here is that, the air on the windward the ridge being suddenly raised to a greater ncreasing the range, the temperature is further l by more expansion and a more copious precipita the result whereas on the leeward side as the air ls to lower levels it becomes gradually drier, and ngly the rainfall rapidly diminishes with the

ave drawn attention to the diminished velocity of the wind r as compared with the open sea (p. 125). From the it that an envelope of stiller air or air of less velocity than the prevailing wind blood over the land, and by it- force the prevailing wind to a greater height than tending ce the rainfall. If the forehead rise within a few miles ght of 200 or 300 feet, the result is very striking when the om the sea blows straight upon it. Thus at Spittal near , on September 18, 7, a N.E. wind blew straight ashore it mited velocity of 25 miles an hour. To eastward the sky ently clear down to the horizon, but to westward all the beyond a mile from the shore was enveloped a dense mist or fog. About 1½ to eastward of the on the shore, the thinnest rack of cloudlets was e without intermission from the deepest stainless blue of the it as they drifted landward increased so rapidly in volume ty that the zenith was three fourths covered with cloud- r phenomenon was seen in September 1879 on board the steamer at the precipitous cliff of Hoy Island, Orkney. touched just cleared away, and a strong W.N.W. wind was straight against the cliff. The sky was absolutely cloud round except the upper 300 feet of Hoy Hill, 1570 feet high, as enveloped in a thick mist that stretched away to wind om distance to westward of the steamer's course, which out rock to rock! The western termination of the as the thinnest rack of cloud, which emerged unceasingly blue sky at a distance not less than 1 mile to wind- the cliff. The containment parts of the cloud itself were in motion eastward but owing to the fresh accessions it was centre, the cloud itself appeared stationary. Thus l was forced upward into the atmosphere for some consider- time to windward of the ridge lying across its path. the air over the land on the wind, and the con- e with it that explain how it is that during of very little rain from the north-east the rainfall over the s of the Firth of Forth, the Moray Firth, and the Pentland ncreased to the north-east so much in excess as compared e rest of Scotland. The same principle explains the heavy on plains at some distance from the range of hills lying he wind, particularly on the side of the rain bringing winds.

short intervals of time the heaviest rainfalls occur rnadoes, water-spouts, and some other forms of the nd, the reason being that not only is there rapid ion due to the rapid ascent of the air, but also great tion is produced by the extreme velocity of the gyrations round the axis of the tornado. On August 6, 3·12 inches of rain fell at Camberwell, London, hours and seventeen minutes. Of heavy falls be mentioned 4·60 inches in London, April 13, 6·00 inches at Tongue, September 7, 1870, 5·36 in Monmouthshire, July 14, 1875; 6·62 inches at Seathwaite, Cumberland, November 27, 1848; an inches at Drishaig, Argyllshire, December 7 to 8. But it is in lower latitudes that the heaviest single s have been recorded. The following are among th remarkable:—at Joyeuse, France, 31·17 inches in t two hours, at Genoa, 30·00 inches in twenty four ho Gibraltar, 33·00 inches in twenty-six hours; on the hill Bombay, 21·00 inches in one night; and on the Hills, India, 30·00 inches on each of five successive

As regards the ocean, there are no available dat which an estimate could be formed as to the a of the rainfall, since the rainfall statistics of the must be regarded as giving hardly anything mo the comparative frequency of the fall. It is, h certain that the equatorial belt of calms in the A and Pacific between the trades is the region where th rainfall reaches the maximum, and the parts of oceans are the rarest which are the longest wit belt of calms as it shifts its position northward and ward with season. While the cloud screen is undou dense and the rainfall frequent and heavy, the observations of the "Challenger" and "Novara" that the statements generally made as to these poi greatly exaggerated.

In the regions of the trades the rainfall is ever small over the open sea, seeing that the trade-wi essentially an outflow from anticyclonic regions, an original dryness is to a large extent maintained then course is directed into regions which becon stantly warmer. Thus at Ascension, lat. 8° 15′ S. is throughout the whole year within the S.E. trad mean rainfall for the two years 1851-55 was on inches. At St Helena, which lies constantly wit same trades, five years give a mean rainfall of 5·36 on the coast; but in the same island at a height o feet the annual amount rises to 23·98 inches. Eland and some other islands in the Pacific, abou 150° W., and for some distance on each side of the e have been pointed to by Scott as practically almo less, as is shown by their containing extensive deposits. These islands are situated somewhat si to Ascension with respect to the zone of calm Mauritius the annual rainfall on a mean of fou was 30 inches at Gros Cailloux, but at Cluny, o miles distant, for the same four years it was 146 in regard to which Meldrum remarks that at Cluny in the vicinity of mountains and forests, in the east of the island, and thus directly exposed to the wind as it arrives from the sea, the rainfall in alm month is from four to six times greater than a Cailloux on the north-west coast, where neither mo nor forest exists, and where the S.E. trade arriv siderably drained of its moisture.

From what has been said it is evident that the l rains will be brought by the winds which have tr the greatest extent of ocean within the tropics, and accordingly of all ocean winds have the highest temp and humidity. These conditions are most com fulfilled during the summer months of the n hemisphere by the winds which, commencing fro lat. 30° S., blow home on southern Asia as the well S.W. monsoon of these regions. Accordingly it is winds of this monsoon that a larger rainfall is dist over a larger portion of the earth's surface than anywhere else in any season; and this large rai in many regions still farther greatly increased mountain ranges which lie across the path of th bringing winds.

It is on these winds that the rainfall of India depends. Along the whole of the west coast fr

f Cambay southward, and on the Western Ghats, ntall is excessive. The following are some of the nteresting annual means in inches beginning with y and proceeding southwards: Bombay, 74; am, 217; Mahabaleshwar, 252, Ratnagiri, 101, 255; Goa, 102, Karwar, 115; Honawar, 139, lore, 134; Cannanore, 132, Calicut, 116, and , 114. In the west of Ceylon the rainfall is also being at Colombo 87, at Galle 91, and at ura, at some distance inland among the hills, 149 the S.W. monsoon is drained of much of its re in crossing these mountains, a greatly diminished is distributed over the interior and east side of and on the eastern slopes of Ceylon.

ow we cross to the eastern shores of the Bay of , we again encounter an excessive rainfall along the and up the slopes of the mountains looking down on Thus from south northward the following are the more characteristic rainfalls in inche ry, 102; Port Blair, 116, Mergui, 152 Tavoy, Maulmain, 189; Rangoon, 100, Bassein, 98, ay, 212, Akyab, 198, and Chittagong 101. On er hand, at Thyetmio, inland on the Irawadi, the rainfall is only 48 inches.

have shown how, in accordance with the peculiar ution of pressure in India in summer, the monsoon ted up the valley of the Ganges as an E.S.E. wind, uting on its way, even to the head of the valley, its ous rainfall the moisture it has brought from the Ocean and the Bay of Bengal. The rainfall does end farther westward than the basin of the Ganges, e precipitation is most copious along the lower yas, the largest falls being recorded at heights 000 feet, being, as pointed out by Hill, near the which the summer monsoon is cooled just below -point. The following are some of the larger rain inches, beginning with the more western Mus 95; Nami Tal, 92; Khatamandu, 57, Darjiling, Kurseong, 154; Buxa, 219; Kuch Behar, 131.

rainfall is very large in the north east angle of the Bengal and thence northwards towards Bhutan, or angle where the summer monsoon from the bay round to a westerly course on its way up the . Thus at Noakhally, on the coast, it amounts in o 109; at Tura, on the Brahmaputra, immediately of the Garo Hills, 129; at Silchar and Sylhet to d, 117 and 155; whilst at Cherrapunji, on the Hills, it rises to 493·19 inches on a mean of twenty ars. This last rainfall is the largest known on the he causes of which are the highly saturated state monsoon on its arrival at the lower Ganges, the ountain range of Burmah to eastward of Bengal, urns the monsoon to the north, and the protrusion rds of the Khasi and Garo Hills so as to lie in the that branch of the monsoon which passes from the anges into the basin of the Brahmaputra above ra. The consequence is that the highly saturated he monsoon in its passage across the Khasi Hills is ly raised to a height of about 6000 feet, and being reduced far below the point of saturation the undant moisture is precipitated in unequalled of rain. The amount of the annual rainfall at all laces is determined, essentially if not altogether, by s of the summer monsoon, the relative intensity of over India may be taken to be fairly represented by nfall of July

rains which accompany the N.E. monsoon of the months may be represented by the rainfall for y. These are heaviest in Ceylon, especially on its opes, and in southern India, or where the N.E. monsoon arrives after having traversed a large ex ocean. The fall for the month exceeds 6 inches large portion of the east coast, whilst at Colombo west the rainfall is only half that amount, and farthe at Pattalum the January rainfall is only 1·82 inch southern India the amount varies from about 1 to 2 Blanford pointed out in 1873 (*Phil. Trans.*, vol. 618) that, while the surface winds of northern India ter are northerly, on the Himalayas, especially the west portion, southerly winds prevail during the cold Hence these upper southerly winds which bring the rains to the Punjab, Upper India, and the highla Assam. It is further to be noted that winter rai occurs in Central India, where the prevailing surface are from east and north east. The mean rainfall of at Mussoorie 1·2700 inches and at Naini Tal 2·86 and in Assam, at Sibsagar, 1·13 inch. Over a larg of the east side of southern India from Nellore sout including Ceylon, the maximum rainfall for the year in the months of October and November.

Rainfall of the Malayan Archipelago and Australia. Un direction of the late Dr Berghaus systematic observations rainfall of the Malay archipelago were begun in 1879, the of stations being 150. The result of the first three years the mean annual rainfall over the archipelago varies from inches in Timor to upwards of 200 inches in some spots am western slopes of Sumatra. But the most important featu rainfall in its relation to climate is not the absolute amou fall annually, but rather the manner of its distribution the months of the year. Over the greater number of the rain falls copiously every month, but as regards some of the the year is divided into dry and wet season as marked as in the climates of India. The key to this essential differen the climates is the distribution of atmospheric pressure du months of the year from south eastern Asia to Australia, w resulting prevailing winds. During the winter months atm pressure is high in south eastern Asia and low in the in Australia, the difference being about three quarters of Since between these two regions the fall in the mean pr practically uninterrupted, the Malay archipelago lying them is swept by northerly winds the 11th. As these win traverse a great breadth of ocean in their course, they ar highly saturated state, and consequently deposit copious particularly on the northern slopes of the higher islands in the month the rainfall over the islands without exc large, the mean monthly amount being in many cases more inches. These winds continue their course to outward tow low-pressure region in the interior of Australia, and deposit north coasts of that continent a monthly rainfall ranging to from 11 to 20 inches. On advancing into the interior, t amount gradually diminishes at the successive telegraphic to 3·50 inches at Alice Springs near the tropic of Capricorn amount of the rainfall for any particular year, and the distan the coast to which the rains penetrate inland depend essent the height of the winter pressure of south eastern Asia as c with the low mean pressure of central Australia, by wh strength of the northerly monsoon is regulated.

On the other hand, during the summer of the northern hem pressure is high in the interior of Australia and low in Ch mean difference being about half an inch. Between the two the fall of the mean pressure is continuous and uninterrup a consequence southerly winds prevail over the intervening pelago. These winds, as they advance from the continent in latitude, are absolutely rainless in the north of Australia, Timor and the other Malay islands which are separate Australia only by a comparatively narrow belt of sea. Du three years no rain whatever fell in Timor in July and Au the fall in June, September, and October was small. As t the winds pursue their course to northward, they rapidly moisture from the sea, so that by the time they arrive at A they have become so saturated that the monthly rainfall th to nearly 30 inches. Again at some distance to the wes rain falls more or less regularly every month, the amount ing in proportion to the extent of ocean traversed by t winds, which advance towards the land from the dir Australia. These marked differences among the climates Malay archipelago, which, since they really depend on t graphical distribution of land and sea of the part of the glob be regarded as permanent differences, have played no incons part in the singular distribution of animal and vegetable lif characterizes the archipelago.

ly the prevailing wind in West Australia is N.W. and the reaches the maximum for the year, whereas in January the S.E., and the rainfall is the minimum. Southerly in since the winds of the southern half of South Australia and are from the south, and thus blow toward warmer regions, ntall is often at the annual minimum, or it is small. But ding the coast and proceeding northwards, the wind becomes n N.E., and ultimately N. in the north of Queensland. its prevalence of oceanic and open-sea winds, the rainfall time of the year rapidly rises over the whole of the eastern ull at Cape York it is about 90 inches. In the basins of the and Darling rivers, which are shut off from the east by the in ranges of New South Wales, the rainfall is only about an d a half. On the other hand, to south of the latitude of , including Tasmania, the low summer rainfall occurs in winter ose regions which slope northwards the sea. On crossing ntain range of Victoria into the basin of the Murray river, ntall rapidly diminishes. In the north of New Zealand the rainfall is the heaviest, but farther south, where westerly ail with considerable steadiness through the year, the rainfall is nally distributed through the months, and, as the prevailing re westerly, the heaviest rainfall is on the west of the islands. Hokitika on the west near sea-level, and not far from a lofty f mountains to the east, the annual amount reaches 120 and at Bealey inland at a height of 2104 feet it is 106 At Wellington the annual rainfall is 52 inches, at nd 46, at Dunedin 31, and at Christchurch 25, thus , in the rainfall of the two sides of the island, extremes s great as in Scotland.

ufall of Europe.—As regards rainfall, Europe may be ently divided into two distinct regions, western and n Europe, extending in a modified degree through erior of the continent into Siberia, and the countries ng on the Mediterranean. A vast ocean on the one a great continent on the other, and a predominance erly winds are the determining circumstances in the ution of the rainfall over western Europe. Hence niest regions are to be found in the west, where ain ranges stretch north and south. The annual exceeds 80 inches over a considerable district, ng the greater part of Skye and portions of the s of Inverness and Argyll to the south east, in the istrict of England, and in the more mountainous of North Wales, these three districts being the in Europe. As Ireland presents no continuous of mountains opposing the westerly winds of the e, no Irish rain gauge shows a mean rainfall of 80 A point of some interest is suggested by the rain the counties of Kirkcudbright and Dumfries in d. These counties offer to the westerly winds a t valleys sloping south to the Solway Firth, which ecessively a diminished rainfall on advancing east ll at several places in Nithsdale and Annandale it t exceed 40 inches. But in Eskdale, farther to the e rainfall instead of falling increases to about 60 The reason is that the westerly winds are ted in their onward course by the range of hills by Eskdale is bounded on the east, in surmounting the winds are much reduced in temperature, and their moisture falls in copious rains immediately ward of the ridge. The cause of the larger rainfall dale is thus analogous to that of the large rainfall coast in the north-east of the Bay of Bengal ately under the Assam range of mountains. In d the largest annual rainfall is 146 inches at Seat- in the Lake district, in Scotland 128 inches at oe in Argyll, whilst in Ireland the largest is only hes. The driest part of the British Islands is an ve district to south-south-west of the Wash, with a of about 21 inches. A large extent of England, the more important agricultural districts in Scotland, rainfall under 30 inches: the greater part of d, and nearly the half of Scotland, have a rainfall not ng 40 inches: but in Ireland it is isolated patches at show a rainfall less than 40 inches.

In the west of Norway the rainfall in inches is Bergen, 51 at Aalesund, 16 at the Naze and in the Isles, falling to 10 at the North Cape. At Chri Upsala, and a large part of the east of Scandina rainfall is about 21 inches, falling to 16 inches north coast of the Gulf of Bothnia. In Russia and it rises only at a few places to 20 inches, several of this extensive region having an annual rainfall o 3, or even 2 inches. The rainfall of Spain present extremes—from 68 inches at Santiago to 13 inc Saragossa. In France and the plains of Germa average varies from 35 to 20 inches, but in moun regions these figures are greatly exceeded, rising all gradations to upwards of 100 inches at some p the Alps.

An important distinction between the manner o bution of the rainfall in the west of Europe and a inland places is that the greater part of the annual q of the west falls in winter, whilst in the inter amount in summer is greater than in winter. The of January and July shows this in a very manner. The summer climates of the extreme of Europe and North Africa are rainless, and over sive regions in the south of Europe adjoining th rainfall does not amount to an inch. Over the regions the prevailing winds of summer are northe hence the drought which characterizes them. On th hand, the rainfall in the interior of the continent is In January the maximum rainfall occurs on the mo and high grounds overlooking the Atlantic, a minimum on the plains of Russia.

Owing to the way in which Europe is broken up seas which diversify its surface, the time of the yea the rain attains the maximum differs greatly in d regions. This phase of the rainfall occurs, indeed, ing to locality, in all months except February, Mar April. The month of occurrence of the annual ma rainfall over Europe is shown by fig. 18. A simil

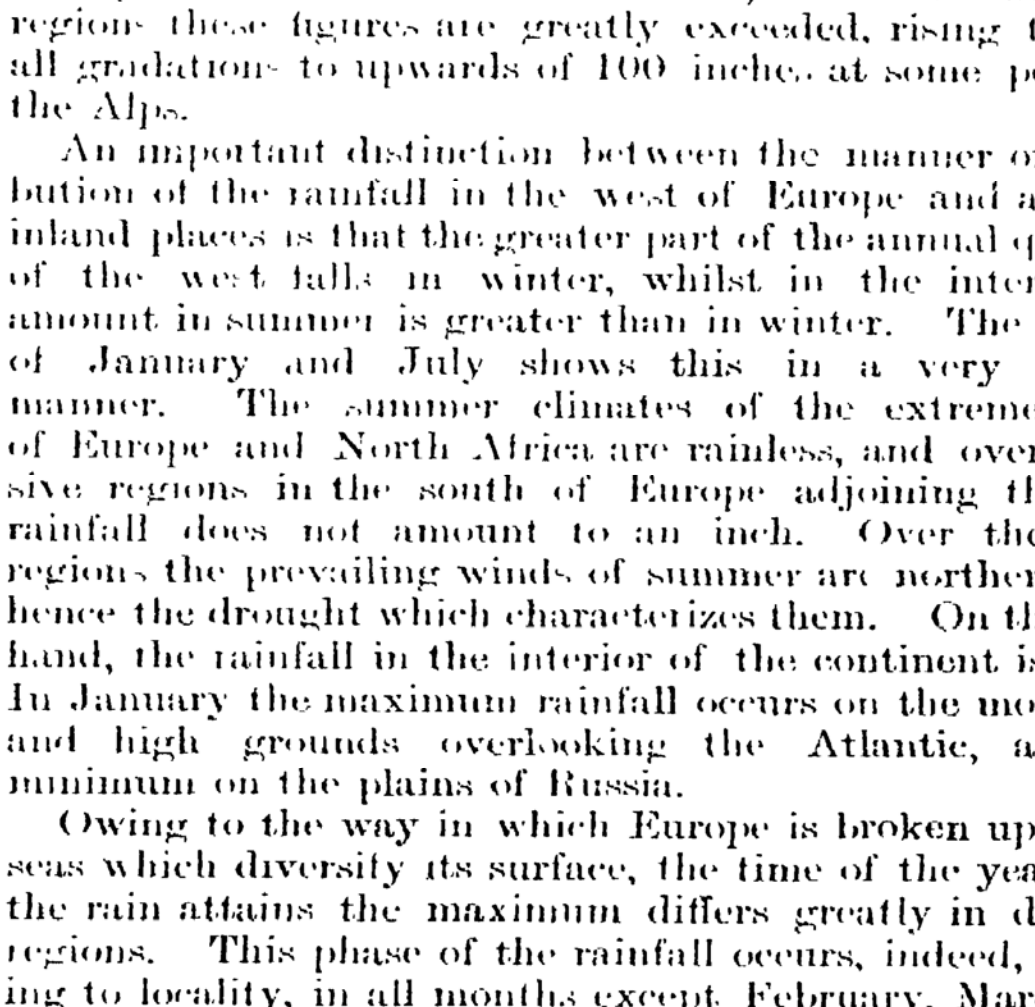

FIG. 18. Showing Month of Maximum Rainfall in Eur

representing the month of least rainfall shows still uniformity in a regular succession of the months in from region to region. Thus the month of least ra January on the lower Volga, February in western Rus the greater part of central Europe, March in the n France and south of Great Britain, April farther to the

n Scotland north of the Grampians, June in Orkney, nd, Iceland, the west of Ireland, and the north-west nce, and July over the whole of the south of Europe. riest month occurs nowhere in Europe in any of the onths from August to December.

fall of North America.—West of the Rocky Mountains the is very unequally distributed, the annual amounts varying 6 inches at Astoria, near the mouth of the Columbia river, ches at San Diego on the coast, and 3 inches at the head of lf of California. Over the whole of the region between the e and Rocky Mountains the rainfall at all seasons is extremely this being indeed that feature in the climate to which the on of the cañons of that region is chiefly to be referred. On er hand, in the United States and Canada to east of long. 100 distinguishing feature of the rainfall is the comparative eness of its distribution, an annual rainfall exceeding 50 occurring only over restricted districts, and a rainfall as low nches being scarcely met with anywhere. The regions where nfall exceeds 50 inches are Florida, the lower basin of the ippi, and the Atlantic seaboards of Nova Scotia and New nd.

nuary the annual maximum rainfall occurs over the whole west coast from Sitka to lower California, but in the r between long. 120 and 95° W. the amount is everywhere and over a considerable part in the south-west of this region falls. The region of largest rainfall extends from Louisiana t Virginia, where the mean varies from 4 to 6 inches. Over the whole of the Dominion of Canada, by much the greater the winter precipitation is in the form of snow, which has arefully measured and recorded by the Meteorological Ser- The average snowfall for January exceeds 30 inches at St Newfoundland, in Anticosti, Prince Edward Island, and y other regions.

uly the rainfall is everywhere small in the west, a large f this extensive region being absolutely rainless. table dryness of the climate at this season is due to the N W that set in towards the low pressure of the interior, which low towards warmer regions. The rainfall to the east of the Mountains is distributed by the winds which are connected he low-pressure region of the interior and with the high- e region of the Atlantic. The result is two regions of larger , the one in the south-east of the States and the other to the the lakes. The summer winds of the south-eastern coasts are rly, and as they are anticyclone in their origin and have in ourse traversed some extent of ocean, they arrive well but not aturated, and pour down a rainfall in July of 6 inches and ds along the coasts and for some distance inland from Louisi- Chesapeake Bay. Further, since in July these winds attain naximum force and persistency, the rainfall at the same aches the maximum along the whole coast from Boston to istance west of New Orleans. Since the summer winds blow line of the Alleghany mountains and not across them, the l diminishes in ascending their slopes. The comparative eness of the rainfall over the eastern States is the necessary of the winds' passing into higher latitudes, and, therefore, regions. A broad region where the rainfall is less than on de of it, extends from Michigan to the south-west as far as an River. To the west of the lakes the rainfall rises above es, and, since over this region the winds become somewhat y as they flow towards the low-pressure area, it is probable e larger rainfall of this prairie region has its origin in no degree in the evaporation of the lakes. On ascending the reaches of the Mississippi, the amount diminishes, but y falls lower than 2 inches, being thus analogous to the r rains of the Upper Ganges. On crossing the water-parting e basin which drains into Hudson Bay, we encounter E. and winds laden with vapour licked up in their passage over Hud- Bay, which they distribute in a generous rainfall of probably inches over the rising colonies of Manitoba and Saskat- n. An important point in the climate of the States is that early the whole of the extensive region stretching between anies and Rocky Mountains, except the south coast already d to, the annual maximum rainfall does not occur in summer spring, the month of largest rainfall in the great majority es being May. In the basin of Hudson's Bay July is the of largest rainfall.

fall of Central and South America. The following are, in the larger and more interesting annual rainfalls round the —Vera Cruz, 182; Belize, 75; Maracaibo, 163; Caracas, Georgetown, 95; Paramaribo, 142; Cayenne, 140; Para, 71, nbuco, 109; Buenos Ayres, 34; Bahia Blanca, 19; Puerto 102; Valdivia, 109; Valparaiso, 100; Serena, 93, Lima, a large part of Peru, nil. A remarkable feature of the of South America is the large amounts that fall in the of the Orinoco and Amazon; the fall is 91 inches in the upper basin of the Madeira, and 112 inches at Yquitos (la S., long. 72° 57' W.). The reason is that this immen where pressure appears to be almost constantly low, i- oper highly saturated winds that blow from the equatorial A Quite different is the distribution of the rainfall over Plata basin. The annual falls, in inches, are 92 at Jonv at Corrientes, 44 at Monte Video, 36 at Parana, 24 at S 22 at San Luis, and only 6 at Mendoza. The fall rapidly ascending the eastern slopes of the Brazil mountains fac South Atlantic, thus, while the amount at Rio Janeir inches, on the hills to northward it is 116 inches.

In January northerly winds prevail on the south coast Gulf of Mexico and the Caribbean Sea, and as they hav origin in the high pressure of the American continent, crossing the equator into lower latitudes, the January ra these coasts is comparatively small. In July, however, the ing winds are easterly, and as they have traversed a large e the equatorial waters of the Atlantic they are highly sa and consequently the July rainfall of these coasts is ver very large. The following are, in inches, the January a rainfalls: Caracas, 1·00 and 14·04; Guatemala, 0·28 and Vera Cruz, 2·49 and 33·90. The seasonal distribution rainfall in the basin of the Amazon is the reverse of th January the position of the belt of calms is about lat. 3° as pressure is relatively low over the basin of the especially its southern slope the trades and the west po the region of calms mutually spread their highly saturated the whole region as far as the Andes, resulting in one of t widespread heavy rainfalls anywhere to be met with other hand, since in July the belt of calms is about lat the saturated atmosphere of the tropical regions no longer the Amazon, but is carried westward into the Caribbean Sea of Mexico. Hence at this season the rainfall of the Amazo is small. The following are, in inches, the January an falls: Para, 6·51 and 3·26; Manaos, 7·93 and 1·82; Madeira, 15·90 and 0·30, and Yquitos, 10·24 and 4·26. La Plata in January pressure is low, and as winds conse blow from the upon the region of low pressure the is large; but as pressure is high in the interior in July the in that month is small. The following are, in inches, the and July rainfalls:—Buenos Ayres, 2·37 and 1·70, Para and 1·32; Corrientes, 5·21 and 2·67; Jonville, 14·26 an and San Luis, 2·62 and 0·00.

Rainfall of Africa. As regards the rainfall, Africa pres greatest diversity in its climates. The following are the amounts in inches at various points on or near the coa Said, 2; Alexandria, 8, Tunis, 13, Algiers, 31, Oran, 17, M 50, mouth of the Senegal, 17, Goree, 21; Sierra Leo Christiansborg, 23, St Thomas, 40; Gaboon, 106, Loan Cape Town, 23, Mossel Bay, 12; Port Elizabeth, 24, Dur Zanzibar, 58, and mouth of the Zambezi, 61. In the nort continent, the rainfall rapidly diminishes inland and over desert of Sahara practically none falls. In the interior o it diminishes, the amount at Laghouat being 17 inches, Biskra 9. In Egypt the rainfall is limited to a narrow str the coast; at Cairo the annual fall scarcely amounts to The January and July rainfalls are in inches, as follows Said, 0·46 and 0·00, Alexandria, 1·95 and 0·20; Algiers, 0·04, Biskra, 0·56 and 0·03; St Louis (Senegal), 0·28 an Goree, 0·00 and 4·06; Sierra Leone, 0·69 and 21·20, Christ 0·50 and 2·00; Katunga, 0·11 and 1·76, Gaboon, 9·35 an Cape Town, 0·28 and 3·83, Durban, 5·00 and 1·70; Preto and 0·71, and Zanzibar, 2·02 and 2·35. At Zanzibar the rains occur about the equinoxes, the mean for April bein inches, and for October 6·80 inches.

In the case of this as the other continents, the explanati different amounts is to be had in the seasonal changes of w the north the winter rains are to a very large extent the penitment of the Mediterranean storms of that season, but in pressure is diminished in the interior and increased in the to the north west, resulting in strong steady northerly wind as they advance into hotter regions are unaccompanied w The heavy summer rains from Senegambia to the Gold C due to the strong monsoonal winds which set in tow interior thus drawing over these coasts the highly saturat the belt of calms and of the trades immediately to the no south of it. Since in winter the belt of calms is remov latitude farther to the south, and the temperature of the n greatly reduced, it follows that the winds blowing on the from the sea are drier and less strong, and consequently the is small. At Sierre Leone the absolutely driest month is F 0·31 inch, and the wettest September, 29·15 inches. On t hand, at Gaboon (lat. 0° 25' N.) the dry season is from August, when the belt of calms is farthest to the north; absolutely rainiest about the equinoxes, the mean of Mar 14·70 inches and October 19·52 inches. At Loanda (lat 8 the annual amount is only a tenth of what falls at Gaboon

, Tarum (on the south west of Jutland) 12, Copen
23, Vienna 35, Ofen 19, Schemnitz 12, Milan
este 6, Salerno 3, Madrid 3, and Lisbon 1
enland the number of days exceeds 80, and this
s nearly reached in Newfoundland and the north-
board of Nova Scotia At Quebec the mean days
w are 66, Halifax 64, Winnipeg 54, Detroit 34,
lenry 13, St Louis 11, mouth of the Columbia
, and Charleston, S.C., 2 In Europe the time of
r when snow falls most frequently is December and
, except in the south of the empire, where February
month of the most frequent occurrence of snow.
the north of a line drawn from the entrance of the
Gulf of Finland through Warsaw, Cracow, Salzbu
Santiago March is the month of maximum occurre
the great majority of instances; while to the south
line it is January and in several cases December.

The largest falls of snow occur in the Antarctic r
as well attested by the magnificent icebergs of
snow which break off all round from the lofty walls
that engirdle the Southern Ocean Excepting perhaps
Dominion of Canada, no data have been anywhere co
from which even a rough estimate could be forme
the mean annual amount of snow that falls in di
parts of the globe.

Snow Line The snow line marks the height
which all the snow that falls annually melts during su
No general rule can be stated for this height in di
climates owing to the many causes determining it.
are the exposure of mountain slope to the sun (and
other things being the same, it is higher on the sout
on the north sides of mountains), exposure to th
bringing wind, the steepness of the mountains, a
degree of dryness of the air. Hence the position
snow line can be known by observation only. It fal
little on either side of the equator to lat. 20°; fro
20° to 70° it falls equably, but from lat. 70° to 78°
more rapidly. To this general rule there are many
tions. It is 1000 feet higher on the north than the
side of the Himalayas, owing to the larger snowfall
south, and the greater dryness of the climate of the
side, and therefore the greater evaporation from the
there. It is higher in the interior of continents tha
the coasts, because the precipitation is less and summ
greater. In the Caucasus it is 11,063 feet high, bu
8950 in the Pyrenees. In South America it rises fr
equator to lat. 18°, and more on the west than on t
slopes of the Cordilleras, owing to the large precipita
the east and small precipitation and arid climate of t
side of that chain of mountains. It is as high in l
S. as in 19° N., but south of that latitude it rapidl
owing to the heavy rains brought by the moist
winds of these regions. In the south of Chili it i
feet lower than in the same latitudes in Europe, an
feet lower than in the extremely arid climates of the
Mountains.

Storms. If weather charts representing a large
the northern hemisphere be examined, two distinct s
of pressure are seen which change their forms and po
on the earth's surface from day to day. The one
systems of low pressure marked off by concentric
enclosing pressures successively lower till the ce
approached; and the other systems of high p
marked off by concentric isobars enclosing pressures
successively higher towards the centre. The fo
the former called cyclones, and the latter anticyclones.
areas of low pressure are the distinguishing charact
of the hurricanes and typhoons of tropical regions,
the ordinary storms of higher latitudes, and they
be conveniently grouped under the general name of cy

ity increase at those places towards and over which
nt part of the storm is advancing, and fall at those
over which the front part of the storm has already
. In other words, the temperature and humidity
pressure falls and fall as pressure rises. This is
portant climatic significance of cyclones. Thus a
sion of low pressures passing eastwards in succes-
o northward of the British Islands are the essential
ions of open winters; whereas, if the cyclones follow
s lying to southward, the winters are severe. In a
e the broadest feature of weather is an area of rain
or rather somewhat in front of the centre, sur-
d by a ring of cloud, outside which the sky is clear.
recise form and position of these areas have been
by Abercrombie to vary with the type of pres-
istribution, with the intensity of the cyclone, and
he rate of its progress, and they are also influenced
al, diurnal, and seasonal variations.

chief point of difference between American and
ean storms is essentially the result of the mean
pressures to the west and north west of their respec-
orm-tracks. Owing to the high winter pressure in
terior of America, the barometer rises in the wake of
orms of the United States more rapidly, the wind
round more quickly and more uniformly to N.W.,
V., and N. and keeps longer in these directions,
he temperature and humidity fall to a greater
, than happens in Europe. In the New England
and Canada the easterly winds of the storms,
g as they do from the Atlantic, are disagreeably
damp, and misty in a degree and with a frequency
greater than occurs with the same winds in the
n Islands.

e chief points of difference between the hurricanes and
ons of the tropics and the cyclones of higher latitudes
ese:—tropical cyclones are of smaller dimensions,
steeper barometric gradients and therefore stronger
, and advance at a slower rate over the earth's
e. Another point of difference is that a large number
hurricanes of the West Indies and the typhoons of
n Asia first pursue a westerly course, which gradually
es north westerly, and on arriving at about lat. 30°
recurve and thereafter pursue a course to north-east
. The tropical cyclones of the Indian Ocean south
equator also first pursue a westerly course, which
ally changes to south-west, and often on arriving about
lat. 30° recurve to the south east. Many of the cyclo

Inclination of Winds to the Isobars The vorticose of the winds in a cyclone towards and in upon the has been already pointed out. One of the more ant practical problems of meteorology is the deter- on of the angle of inclination of the winds to the s in the different segments of the cyclone, not only he application of the results of the inquiry to the of storms but also to practical navigation. The first ntribution to the subject, based on accurate measure was made by Clement Ley in 1873.[1] From the ations made at fifteen place in north west Europe ed by him he showed that the wind- incline from ls of higher towards those of lower pressure at a ngle of 20 or , that the inclination is much greater nd than at well exposed stations on the coast, the ive angles being 28 55' and 12 49'; and that the t inclinations are with S.E. winds. Then follow N.E., and N.W. winds, the last showing the least tion Whipple has recently compared the winds with the barometric gradients for the five years 1879, with the result that the greatest inclination with S.E. winds, the least 35 with N.E. winds, and n for all winds 52'.

egards the open sea, Captain Toynbee has shown, careful investigation of the great Atlantic storm of 24, 1873, that the mean angle of inclination ed from one hundred and eight observations was e mean at the three selected epochs examined g from 25 to 31°.

ometric Gradient and Velocity of the Wind. In g into the relation of the velocity of the wind to rometric gradient, it is necessary to have some information as to the increase of the velocity with above the ground. Stevenson recently made tions on this point on winds varying from 2 to 44 n hour from the surface up to a height of 50 feet, hich he has drawn the following conclusions: (1) ces passed over in the same time by the wind with height above the ground; (2) the curves ut by these variations of velocity from 15 to 50 gh coincide most nearly with paraboloas (fig. 20)

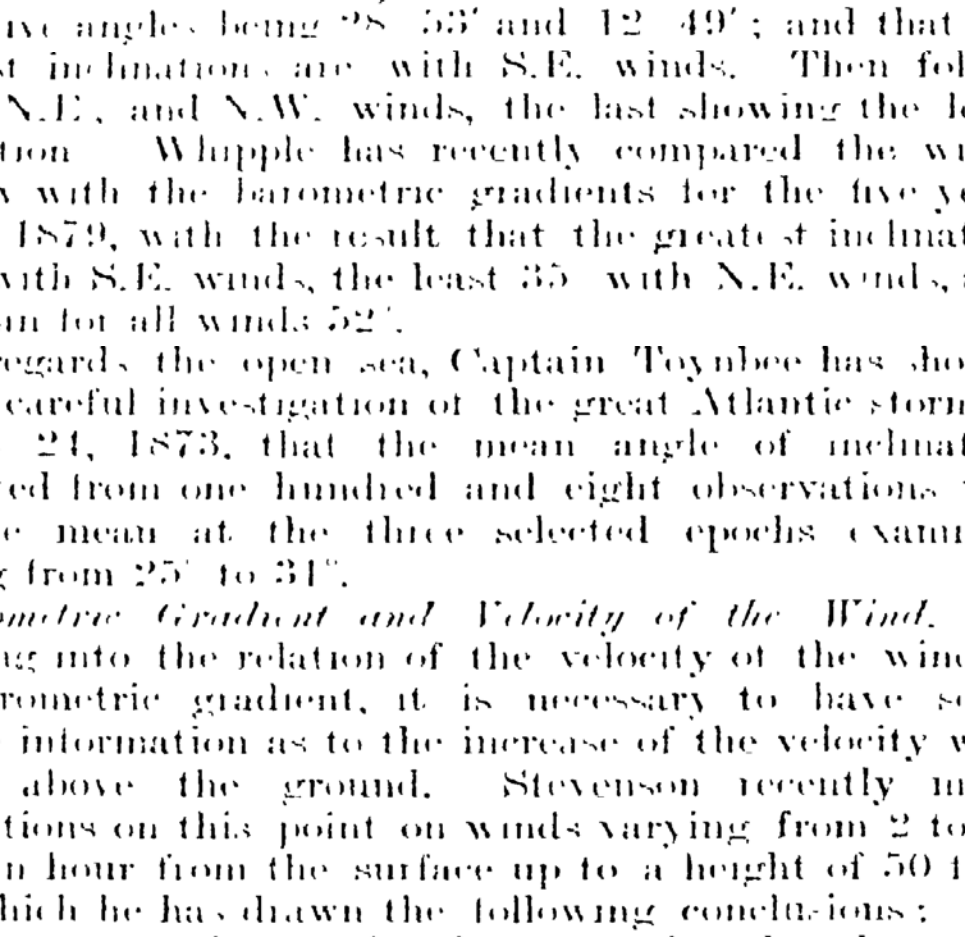

FIG. 20.

their vertices in a horizontal line 72 feet below the ; (3) between 15 feet and the ground there is great ance of the currents, so that the symmetry of the s destroyed; (4) the parameters of these paraboloas directly in the ratio of the squares of the velocities different gales. If v be the velocity of the wind at height H above the ground, the parameter corresponding paraboloa is v^2 (H + 72); and as v va parameter will vary as v^2 or as the square of the of the gale. It follows that, to render wind obser comparable, it is necessary that anemometers be pl one uniform height above the ground, and that st height not lower than 15 feet above the surface. very desirable that the inquiry were prosecuted height of 100 feet; and it is of the utmost importan the variation in the diurnal velocity be at the sam determined at different heights from 15 feet upwar

Stevenson also made wind observations on the Hill, Arthur's Seat, and the Pentland Hills, in the of Edinburgh, up to a height of 1600 feet above se It is from observations made at stations on kno peaks at different heights above the sea, and at d heights above the surfaces of their summits, th problem of the variation of the wind's velocity at d heights with the same barometric gradient can be tained. In carrying the inquiry to considerable h the results cease to be comparable with those o at lower levels, unless in those cases where neighb heights are available for data from which the bar gradient at the observed height can be calculated results of observations as to the velocity of atmo currents at very great elevations in the atmosphere c from the apparent movements of the higher clou altogether incomparable with the winds near the su the earth, for these among other reasons:—the hei the clouds can be at best but imperfectly ascertain motion of the clouds, particularly the higher cloud be only apparent, it being sometimes difficult to dist between the formation and dissolution of clouds an motion; and above all, since the higher clouds are the accompaniments of the greater weather change movements as the result of barometric gradients t a knowledge of which we are absolutely powerless a single step.

As regards surface winds, Clement Ley in 18 Whipple more recently and with greater fulnes calculated the mean wind velocities for twelve gradi the gradients being derived from the daily weather of the Meteorological Office for the five years 1875 at 8 A.M., and the corresponding wind data being o from the hourly readings of the Kew anemograph barometric gradient is for 15 nautical miles, a following are the velocities for the twelve gradients mean of the year:—

Gradient. inch	Velocity.	Gradient. inch.	Velocit miles
0·002		0·017	15·0
0·005		0·020	16·5
0·007		0·022	19·1
0·010	9·2	0·025	22·0
0·012	11·6	0·027	22·0
0·015	12·6	0·030	25·5

The influence of season is very strongly marked velocities for the same gradients in order are—Oct December, 12·5 miles; July to September, 12·6 January to March, 14·8 miles; and April to Jun miles. From those observations of Whipple it that during the six months when the temperature is the velocity for the same gradients is least, while the is greatest during the six months when the tempera rising, and absolutely greatest during the three ending June, when the greater part of the annual i of temperature occurs. It is evident that the ob increase in the velocity of the wind for the same gr is to be referred to the same cause that brings ab diurnal increase in the wind's velocity, viz., th blowing over a warmer surface than itself.

[1] *Journal Scottish Meteorological Society*, vol. ix. p. 66.

ople has also sorted the winds according to the points of the compass, with results of the greatest . If N.W., N., N.E., and E. winds be grouped r as polar, and S.E., S., S.W., and W. winds as rial winds, the mean hourly velocity of the polar for the same gradients, is 1·1 miles in excess of the rial winds. Now, since polar winds pass into lower es, the surface of the earth over which they blow mer, whereas the surface is colder than the equa- winds which blow over it. It follows that the ed velocity of polar winds is referable to the same ons which result in the diurnal increase in the velocity and the greater velocity for the same nts of winds when the annual temperature is rising, n all these cases the winds blow over a surface of er temperature than their own.

evident from these considerations that for the oment of the law of the relation of the wind's y to the barometric gradient with an exactness nt to warrant us in expressing that relation in a l mathematical formula much yet remains to be done. th, as regards the various formulæ submitted by Mohn, Hann, Everett, and others, we have no but to allow the justness of Strachan's criticism *n Meteorology*, p. 98) that the theoretical values ned by the formulæ do not accord with the actual and that therefore a satisfactory formula is yet to nd. Ere such a formula need be looked for, the ions must be fulfilled for the preliminary work of sup- the observational data required. The "Challenger" ations prove that, with gradients substantially the the velocity of the wind is greater on the open sea ear land; and we have seen that the velocity varies he hour of the day, and generally is increased as the rature of the surface rises above that of the air blow- er it, and diminished as the temperature of the surface elow that of the air. It is evident that observations open sea will afford data for the simplest solution of oblem; but on land the diurnal, seasonal, and non- ic changes of temperature greatly complicate the m, and render necessary for its solution observations lly designed for the purpose. It is not easy to see hese can be obtained but by carrying out the plan pro- in 1875 by Stevenson of establishing strings of well- ed meteorological stations planted sufficiently close he barometric gradients may be determined within the of accuracy required. Observations made twelve daily for a year, at stations so arranged, would the observational data for the solution of this funda- l problem in meteorology. Till some such proposal ried out, the problem remains unsolved, for barometric nts based on the widely separated existing stations o uncertain and rough and the wind observations anting in that comparability which alone can satisfy quiry.

ather and Weather Maps.—Weather is the state of r at any time as respects heat, moisture, wind, rain, and electricity; and a change of weather implies a e in one or more of these conditions. Of these es the most important as regards human interests ose which refer to temperature, wind, and rain; and, ese are intimately bound up with the distribution of spheric pressure, the latter truly furnishes the key to her changes.

se relations are well shown by the International Monthly her Maps issued by the United States Signal Service. Of these or December 1878 is a striking example. This month was terized over the globe by unusually abnormal weather. A rawn from Texas to Newfoundland, across the Atlantic, the of France, and Germany, thence round to south-east, through ack Sea, the Caucasus, India, the East India Islands, and Australia to the South Island of New Zealand, passes thr broad and extended region where pressure was throughou siderably below the mean of December, and this low p was still further deepened in various regions along the line other line passing from Australia, through the Philippine I Japan, Manchuria, Behring's Strait, and Alaska, also mar an extensive region where pressure was uninterruptedly bel

On the other hand, pressure was above the average, and ge largely so, over the United States to west of longitude 96 Greenland, Iceland, the Faroes, Shetland, and a large por the Old Continent bounded by a line drawn from Lapland by Lake Balkhash, Canton, Peking, to the upper reaches Lena. Another area of high pressure extended from Syria, t Egypt and East Africa, to the Cape; and part of a third high pressure appeared in the North Island of New Zealan regards North America, the greatest excess of pressure, 0·19 above the mean, occurred in the Columbia Valley, from w gradually fell on proceeding eastward to a defect from the a of 0·146 inch near Lake Champlain and to northward, rising to near the mean on the north of Nova Scotia. To the nor north-east exceedingly high pressures for these regions a season prevailed, being 0·635 inch above the mean in I 0·500 in the south of Greenland and at the three stations r Greenland, proceeding northward, 0·145, 0·402, and 0·346 r

West Greenland being thus on the west side of the re high pressure which occupied the northern part of the At and on the north east side of the area of low pressure in the and Canada, strong south winds set in over that coast, a temperature at the four Greenland stations, proceeding from to north, rose to 1·1, 8·8, 12·1, and 11·4 above the mea the centre of lowest pressure was in the valley of the St La about Montreal, strong northerly and westerly winds predom to westward and southward, where consequently temperatu below the average, the deficiency at Chicago and St Louis 9·5; and, winds being easterly and northerly in California, t perature there was also under the mean. On the other hand New England States, the greater part of the Dominion of Can West Greenland temperature was above the average. Press much higher at St Michael's, Alaska, than to south-westwa Paul's, Behring's Strait, and hence, while temperature at St was 2·9 below the normal, it was 12·0 above it at St Mi where strongly southerly winds ruled. With these strong ce of pressure, America presented contrasts at least as striking distribution of the temperature. Along the south of Lake M the November temperature was 13·7 above the normal, wh December temperature was 9·5 below it, the differen between the two consecutive months being thus 23·2.

As regards Europe, Iceland was on the east side of the p high pressure which overspread the north of the Atlantic, an northerly winds prevailed there and temperature fell 7·2 be mean, presenting thus a marked contrast to the high tem of West Greenland at the time. In Europe, the area of pressure occupied the southern shores of the North Sea, ex thence, though in a less pronounced form, to south-ea Hence over the whole of western Europe winds were N.E., in the south west of Europe W.; and hence everywhere fr North Cape to the north of Italy temperature was bel normal, in some places greatly so, the deficiency being the south of Norway and 12·2 in the south of Scotland. other hand, on the east side of the area of low pressure wi southerly and temperature consequently high. In some l in Russia the excess above the mean was 15·9, and over proportion of European Russia the excess was not less th This region of high temperature extended eastward into Si far as the Irtish, being coterminous with the western hal anticyclone region of high pressure which overspread Siberia. But over the eastern portion of the anticyclone n winds prevailed with the inevitable accompaniment of l peratures over the whole of Eastern Asia, the deficiency tchinsk on the upper Amur being 6·8. Here again, ju America, Greenland, and Iceland, places with atmospheric equally high presented the strongest contrasts of temp Thus at Bogoslovsk, on the Ural Mountains, pressure was 0 and at Nertchinsk 0·154 inch above the normals, but Bo on the west side of the high pressure area had a temperatu above, whilst at Nertchinsk it was 6·8 below the average.

At this time of the year the mean pressure falls to the m in Australia, but during December 1878 the usually low was still further diminished. Pressure at this season also the annual minimum in the North Pacific and North A and it has been seen that the low pressure of these reg likewise still further diminished. But in the case of the it was attended with a most important difference. The lowest pressure, usually located to the south-west of Ice removed some hundreds of miles to the south-east, and an u development of extraordinarily high pressure appeared to t

erspreading the extensive region of Baffin Bay, Greenland, Faroes, and Shetland. It was to the [illegible] high pressure particularly in its relations to the low pressure region to the st of it, that the extreme severity of the weather in the Islands at the time was due. Now the high pressure was intimately connected with, and doubtless occasioned by, upper atmospheric current from the widely extended low pressure to southward, with its [illegible] centres of still pressure in the North Sea and Atlantic and United States, pressures were respectively 30.50, 30.32, and 30.46 inches under mal. Thus, with the most extraordinary distribution of the high-pressure ver Greenland, the most [illegible] pressures which render r 1879 so memorable, and, the whole globe around undation of the earth's atmosphere essentially the one ames at that time of the year, but the usual irregularities he distribution of the pressure appear to be more pronounced

n the all important features of the areas of high pressure and other and climate into consideration, with the abnormal concentration of aqueous vapour to which they imply, it is evident that, he meteorologist will be in a position to forecast, on e ground, the weather of the coming season for Islands, as to the Atlantic he will require to the data on which the forecasts are based

questions, which the International Weather Maps United States enable us to discuss, are of the first nce in meteorology, whether we consider the amplitude the atmospheric changes they disclose (these being vast as to embrace four continents at one time), became profoundly interesting from their direct on the food supplies and commercial intercourse ons) or regard the larger problems they present, ct towards their solution, which underlie physical hy, climatology, and other branches of atmospheric

The discussion presents the great atmospheric as influenced by oceans and continents, no less subordinate but important part played by mountain extensive plateaux, and physically well-defined n as to determine the development, course, and tion of the cyclones.

Storm Forecasts and Storm Warnings.—It is in tropical tropical countries that an isolated observer may, close approximation to certainty, predict the h of cyclones and hurricanes. In these regions atmospheric pressure and the other meteorological conditions constant from day to day that any deviation, even one, from the average of the hour and season in of pressure, the direction and strength of the wind, direction and amount of cloud, implies the presence at no great distance. Dr Meldrum has practically the problem at Mauritius with great success. Royal Alfred Observatory there the mean pressure el in January at 9 A.M. is 29·966 inches, from falls to 29·901 inches at 4 P.M., then rises to inches at 10 P.M., and again falls to 29·927 at 4 the mean direction of the wind and the diurnal variaboth as regards direction and force, have been stated Suppose then that the barometer is observed after 9 A.M. more rapidly than is due to the usual barometric tide, that in the afternoon it does not the second maximum, or that it continues to fall of rising, or appears, in short, any deviation from an daily march, then it is certain that there is ere an atmospheric disturbance near enough to us to influence the pressure. The direction in he disturbance is from Mauritius is readily known e wind, and the distance of the storm closely mated to by noting the rate and amount of the fall barometer, in connexion with the changes of the d the clouds, the rate and progressive motion of m being known chiefly from the veerings of the For a good many years past notifications have been sent to the daily newspapers when observations s that a storm is not far from the island, stating its posi and probable course from day to day. The scheme storm warnings at Mauritius has been entirely success and the result is of great value, since it shows what may done at an isolated station in the ocean, or what may done in ships at sea. In this connexion it is not poss to overestimate the importance to seamen of a knowle of the hourly variations of the barometer and its m monthly heights over the ocean tracks of commerce.

In passing from Mauritius to the British Islands pass from a region where the forecasting of storms weather is simplest and easiest to the region where i most complex and difficult, particularly for the west districts of these islands. The great difficulty lies in fact that the British Islands are immediately bounded the Atlantic to westwards; and, since practically e storm and nearly all weather changes come from direction, no telegraphic communication of their appro can be received. The Meteorological Office in London therefore no choice but to base the forecasts on such of observations telegraphed to the office as experience shown to be the precursors of storms and other wea changes. The more important of these observations the falling and rising of the barometer taken in conne with changes in the direction and force of the wind. S on the north side of the track of the centre of the st winds are northerly and easterly and temperature low, on the south side winds are southerly and westerly temperature high, one of the most important points t ascertained is the probable path the centre of the cyc storm will take. Though a good deal remains to accomplished in the development of this phase of sto yet much has recently been done in this direction by examination of the changes of pressure in the region the anticyclone contiguous to the advancing storm and the changing positions of the rain area near the centr the cyclone.

As regards Europe, the facility of forecasting sto increases as distance from the west coasts is increa Thus to the middle and eastern districts of the Bri Islands, were a day and night watch established in west, forecasts of almost every storm could be issued, exceptions being those small cyclones or satellite cyclo as they are called, originating within the British Isla themselves, which are frequently characterized at once their severity and by the rapidity of their onward cou In the United States, the system of weather forecastin perhaps the best in temperate regions, a result due the admirable system organized and developed under direction of the late General Myer, and adequately s sidized by the Government, but above all to the facili to detect and track the storms in the region where ne all of them have their origin, to west of the Mississi before they advance upon the more thickly peopled Sta

Meteorology sustained a heavy loss by the death in 1 of Leverrier, who was not only the keenest sighted physicists but also the prince of organizers of system meteorological observation. His last great service to science was the establishment of a system of observat by which the propagation of rain, hail, and other weat phenomena could be followed and recorded from comm to commune over France. This scheme for the invest tion of the vitally important bearing on the meteorol of a country of a comprehensive observation of its rain hail, and thunderstorms, through numerous obser assessing sound local information, is not only emine just in science, but is calculated to be attended with greatest benefits to agricultural and other public intere The practical advantages of the scheme, it need scar

ed, can only be reaped after a very large expendi labour and money in organizing a comprehensive al scheme of observation, systematically and per y carried through and discussed

ther details regarding meteorological phenomena found in the articles ATMOSPHERE, BAROMETER, E, HYGROMETRY OZONE, RAIN-GAUGE, SEA, and OMETER. (A. B.)

TERRESTRIAL MAGNETISM

the preceding portion of this article some account has been the influence which the sun and moon exert upon the air, and the ocean, their effect

ly dealt with. The discussion of the influence of the on what *may* be termed the movables of the earth will complete, however, without embracing an account of the which they produce in the earth magnetism. An account other magnetic observations has already been given under ding MAGNETISM and our task will now be to describe the e a description of the best and most recent instruments by the magnetic state of the earth is determined, and to observatory instruments, those adapted for travellers whether or by sea, and differential magnetometer. We shall then port account of the magnetic survey of the earth and of its ervation, and we shall then investigate the changes co- with terrestrial magnetism depending on the sun and moon. mming this task we shall be led to conclude that the ures variable, and we shall therefore examine whether this con- likewise borne out by strictly meteorological observations. we shall venture on remarks embodying a provisional hypothesis, and our object will be gained if this should be suggest certain lines of thought to those interested in the which may lead them to examine and discuss the very great observations at present existing.

INSTRUMENTS FOR DETERMINING THE MAGNETIC STATE OF THE EARTH.

(*a*) *Observatory Instruments.*

Declinometer.—It is that end of the needle which points to h magnetic pole of the earth of which the position is most ted even when the observation is made in the southern re. The difference of this position from true geographical enote what is called the variation or declination for a the needle. East is often reckoned negative and west . The instrument by which this information is obtained is he declinometer. The unifilar magnetometer, which is n of declinometer now used, is described and figured in ETISM, vol. xv. p. 238.

Dip Circle. The instrument by which the magnetic dip or ion is observed contains a thin needle about 3 inches e centre of gravity of which coincides as accurately as with the axis of motion of the needle. The needle has two nsisting of two very fine cylinders of hardened steel carefully gles to the plane of the needle, and great attention must be keep these axles in a state of perfect polish and clean- ns of these the needle can oscillate freely on two horizontal rounded edges, the one always lying on the one edge and the le on the other. If the centre of gravity coincide exactly axis of motion, and if there be no friction on the axles and the agate edges, the needle must settle into position that its magnetic axis lies in the true line of dip. osition of the ends of the needle is read by means of two opes which move round on a cross piece carrying vernier- the position of the lower end of the needle we move round er microscope until the cross wire in its field of view (extend- he line between the two microscopes) symmetrically cuts enity of the needle. The lower vernier is then read. The ocess is repeated for the upper vernier, and the mean of readings is taken. This mean will accurately denote the of the needle if the circle is properly set.

sources of error in a dip observation are (1) a want of ry in mass, the centre of gravity of the needle not being nt with the axis of motion; (2) the vertical circle being sly set; (3) a want of symmetry in magnetism, the mag is not being coincident with the axis of figure; (4) reason the axis of rotation of the needle not passing through the f the circle; (5) friction and adhesion of the axles as they their agate supports. This last source of error is guarded by taking great care of the axles, and by inserting them into a piece of cork before each observation, the agate s ought also to be rubbed with cork. Then, again, when dle has assumed its position, before reading it is gently tri- ns of a lifter, the handle for turning which is shown in the owards the right. It is then gently lowered, and thus pro- cess is repeated until no apparent change of position is p by the operation.

We shall now describe a complete dip observation. T point is to make the needle to swing in the plane of the m meridian. In order to accomplish this, after levelling the ment, the verniers are set for 90°, that is, for a vertical pos the needle. The whole instrument is now turned round h zontal circle until the extremities of the needle are bisected s the two microscopes, and the position of the vernie horizontal circle is then read. The needle is next reversed e microscope shall view its other flat side. It is made ver face, and the position of the horizontal circle read once See the face of the instrument is turned to and 180°, and th two operations repeated. We have thus four readings of th ontal circle, and if we take the mean of the two half-rev sufficient accuracy the position of that plane for ch vertical. Now this plane must be removed 9 magnetic meridian, for in such a plane the horizontal m the earth would have no resolved portion acting the needle's motion so that the needle would pr be neutral to the solicitation of the vertical magnetic force, and therefore perfectly vertical direction. By this means there obtain the magnetic meridian, and thus know the plane we ought to write for needle. The needle must now in the following positions face of instrument, e face of instrument, w needle to face of instrument, face of instrument, w needle to face of instrument, face of instrument, e needle to face of instrument. Finally, the pole of the need be reversed, by subjecting them with powerful bar magnet direction opposite to that in which they were previously and four observations taken corresponding to the above. Th of the eight observations would thus give us the true di

The turning round of the face of the instrument four times is made to counteract any error due to erroneous setting vertical circle. The reversal of the face of the needle is counteract any error due to the centre of gravity of the ne being quite coincident in the direction of the needle. Simil its axis of motion, and likewise any error due to want of sy of the magnetic axis. The correction for eccentricity is reading both ends of the needle. Finally, the reversing of the needle is intended to counteract any error due to the of gravity of the needle not being coincident in the direction needle (as we assume it to be) of figure.

Dr Joule has also constructed a modification of the dip circle the needle is turned on the line on which it rests in read by microscopes upon

Horizontal Force Magnetometer.—The theory of the in for determining the horizontal component of the earth's m force has already been given in the article MAGNETISM, v pp. 248–249, and the instrument is shown in two forms figs. 28 and 29. The corrections necessary for accurate re explained in a paper by G. M. Whipple (*Proc. Roy. Soc.*, 1

(*b*) *Instruments adapted for Travellers by Land.*

6. *Declinometer.* For travellers by land the unifilar mag (fig. 29), mounted on a tripod stand and duly levelled, is perh accurate kind of declinometer.

For this purpose a small fixed telescope with a transit mirror by of which an image of the sun may be thrown into the field of the telescope, and the chronographical position of the s well as the apparent time of the observation being kno azimuth thus determined. In order that such an observati succeed the following points must receive attention.

In the first place the axis of the mirror must be horizon adjustment of this is made by means of a riding level. S the normal to the plane of the mirror must be perpendicula axis. The adjustment for this is made by a screw attached back of the mirror. Take some object sufficiently eleva reflect it into the telescope; turn the object bisected by of the telescope. Then reverse the mirror in its bearing object remains still bisected by the wire no correction req be made; but if not the screw at the back of the mirror must move until the object is exactly the same position observation. Thirdly, the line of collimation of the tele be perpendicular to the plane of the mirror. In order to this there is a collimating eye piece attached to the tel when the sun is bright may be made to illuminate the cro Now turn the transit mirror until the reflexion of the cha cross wires coincides with the wire themselves, in which line of collimation of the telescope must be perpendicular plane of the mirror. When the correction has been once ma the circle reading of a small vernier which moves with the and always set the mirror so as to give this reading.

[1] *Proc. Lit. and Phil. Society, Manchester*, vol. viii. p.

ese means an accurate reading of the sun's bearing may be
and, the position of the place and the time of observation
nown, there are tables which enable the azimuth to be at
ermined.

oyd's Method of Determining the Total Force. While the
le and the horizontal force magnetometer may be used by
rs in addition to their use as observatory instruments, the
Lloyd has de[illegible] a new method of determining the total
The ordinary method of obtaining this is first to find the
the horizontal force, fr[illegible]ch the total force can be at
termined by the equatio[illegible]tal force = horizontal force ×
dip. This method is, h[illegible], open to objection in high
ic latitudes where the h[illegible]l force is very small and the
the No[illegible]L
Anot[illegible]stru[illegible]ethod this objection is over-
nt f[illegible]nder his method peculiarly
m t be kept [illegible], where a traveller's equip
s the a[illegible]the hat it ly
give[illegible]to an ordinary dip circle in
y kept[illegible]ation. These needles must be
ver e[illegible]other magnets, and their poles
as bef[illegible]
ng the[illegible] have two unknown quantities to determine, the
ce of[illegible]ctic moment of the magnet and the other the
[illegible]nth. We must, therefore, obtain two results,
[illegible]mon[illegible] the product of the earth's total force into the
the e[illegible] of the needle, while the other gives the ratio
order[illegible] quantities.
groove[illegible] determine the former of these, let the needle
over[illegible] wheel of radius *r* attached to its axle as in fig.
[illegible] which let an accurately known weight W be

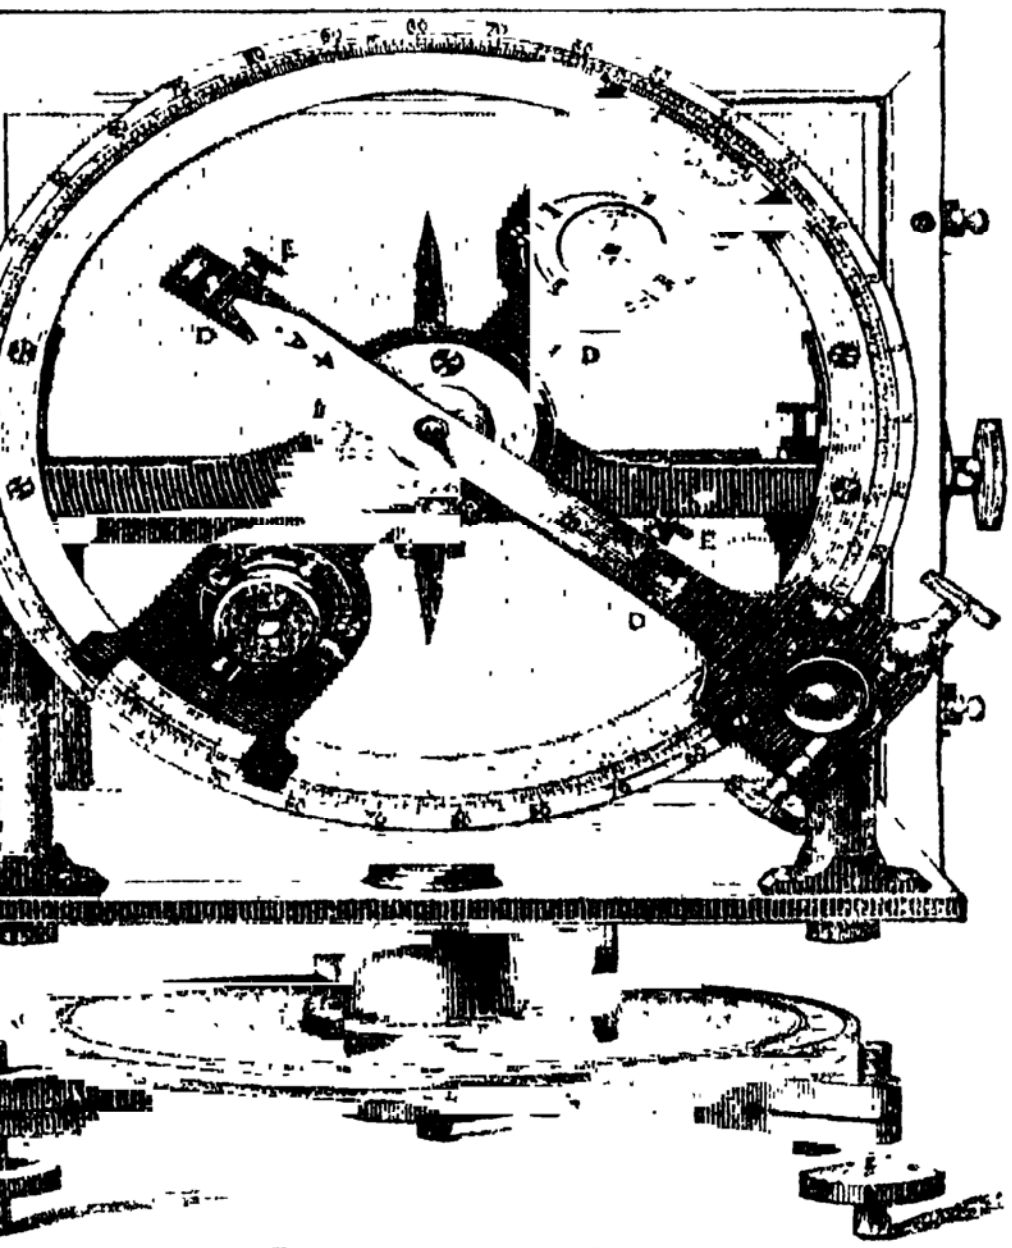

FIG. 21.—Dip Circle.

[illegible]ed by mean[illegible] fine silk thread. The best way of
[illegible]hes is to h[illegible]l with two hooks of precisely equal
[illegible]at each end[illegible]ttach the preponderating weight W
[illegible]of the hooks. W[illegible]ring is done a new position of equili-
will be taken by the needle. If we suppose that *m* denotes
gnetic moment of the needle, that *i* is the angle of dip at the
nd that η denotes the angle which the needle in its deflected
[illegible] makes with the horizon[illegible] sighting being so made
shall be less than *i*, then [illegible] that the needle has been
d out of its position of equilibrium through an angle $i - \eta$.
call this angle u and designate by R the total force
place, we obtain the following equation of equilibrium:—

$$mR\sin u = Wr \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

supposition (which is very nearly but not strictly correct)
denotes a constant force at all latitudes.
ext, in order to determine the ratio between this needle's
d that of the earth, let it be removed and employed to
another substituted in its place.

When using it thus as a deflector it should be laid in a f
an invariable position as in fig. 21. This frame is at right a
the line between the two microscopes, and as both piece
together the best plan is to turn the whole round until the
needle is visible in the centre of the field of the microscopes, i
position it is of course perpendicular to the deflecting need
always keeping to this arrangement we secure an invariable
between the poles of the two needles. Suppose therefore
have employed the needle as a deflector in the above manner
that the deflected needle has thus been made to assume a
denoting an angle η' with the horizon. It has therefo
deflected from its position of equilibrium by an angle $i - \eta'$ (
ing the dip as before); calling this angle of deflexion u', we
the following equation of equilibrium:—

$$R\sin u' = mU \quad . \quad . \quad . \quad . \quad . \quad . \quad .$$

U being a function depending upon the distance of the nee
on the distribution of free magnetism in them.

10. If we multiply together equations (1) and (2), we ob

$$R^2\sin u\sin u' = UWr \quad . \quad . \quad . \quad . \quad .$$

in which u, u' are determined by observation, while W an
be regarded as constants. U is, as we have said, a funct
pending upon the distance of the two needles and upon th
bution of free magnetism in them.

The magnetic moment of these needles is of course liable t
tion, but if they are carefully guarded from contact with
we may imagine that while their intensity alters, becoming
for instance, this nevertheless does not sensibly affect the
tion of the free magnetism within them, in which case the
U may be regarded as a constant quantity. The results
by this method of Lloyd's fully confirm this hypothesis re
U; but it is essential that the two additional needles, the
and the deflected needle, should have their poles at no tim
reversed or disturbed.

Assuming therefore the constancy of the quantity U, its va
be easily determined at any base station where the total f
been determined independently by the ordinary method.

11. Having thus determined the value of U, or at once
(which we may call *c*), let us carry our instrument to a
station and make the requisite observations. We thus obta

$$R = \sqrt{\frac{c}{\sin u\sin u'}} \quad . \quad . \quad . \quad . \quad .$$

As this method is specially adapted for high latitudes, the d
employed (fig. 21) ought to be one for which the agate supp
horizontal, so as to admit of the needle being visible when
is nearly equal to 90°. It will also be noticed that, if the d
needle have the same temperature when it is used in equa
which it has when used in equation (2), then *m* in the one
strictly equal to *m* in the other, and thus no temperature co
is rendered necessary.

12. A slight modification of the method now described
times adopted. Instead of employing separate weights, wh
be easily lost, two small holes are bored in the deflecting
near each end. The one of these is filled with a suitabl
brass peg when the observations are to be made in the
magnetic latitudes of the northern hemisphere, and the
filled in a similar manner when the observations are to
near the southern pole. In this case therefore we must
the instrument as we pass from the one hemisphere to the o
slight change must be made in the formula when this m
adopted, for it is clear that the weight will not now act al
the same constant leverage. If the weight be called W
leverage when the needle is horizontal *r*, we shall have to
equation (1) as follows:—

$$mR\sin u = Wr\cos\eta \quad . \quad . \quad . \quad . \quad .$$

Equation (2) will, however, remain unaltered, and hence
(3) will become

$$R^2\sin u\sin u' = UWr\cos\eta \quad . \quad . \quad . \quad .$$

If the quantity UW*r* be determined at the base station an
c', we shall have

$$R = \sqrt{\frac{c'\cos\eta}{\sin u\sin u'}} \quad . \quad . \quad . \quad . \quad .$$

(γ) *Instruments adapted for Travellers by Sea.*

13. *Azimuth Compass.*—At sea the declination is
observed by means of an azimuth compass invented b
This is exhibited in fig. 22. It consists of a magnet
graduated compass card attached to it. At the side of th
ment opposite the eye there is a frame which projects
from the plane of the instrument in a nearly vertical direct
this frame contains a wide rectangular slit cut into two
a wire extending lengthwise. The eye-piece is opposite th
and the observer is supposed to point the instrument i

er that the wire above mentioned shall bisect the sun's visible . There is a totally reflecting glass prism which throws into e piece an image of the scale of the graduated card, so that bserver, having first bisected the sun's disk by the wire, next read the division of the scale which is in the middle of ld of view. He thus obtains a reading of the sun's position; call this 100°. From this, ng the geographical posi f his station and the time observation, he may de- n azimuth; let us imagine this is 70° W. Thus a g of 100′ corresponds to ion 70° W. Suppose next he instrument is so ad that when the magnetic t the magnet is between e piece and the wire the g is 0. If a thus clear he magnetic meridian is emoved from the position . Let us imagine that the instrument is so graduated that notes a position 30′ E. We have thus obtained the m declination. If the vessel be at rest the plan generally ed is to take the reading of the sun when it is due and also setting, a mean between the two will give that which cords to a geographical meridian.

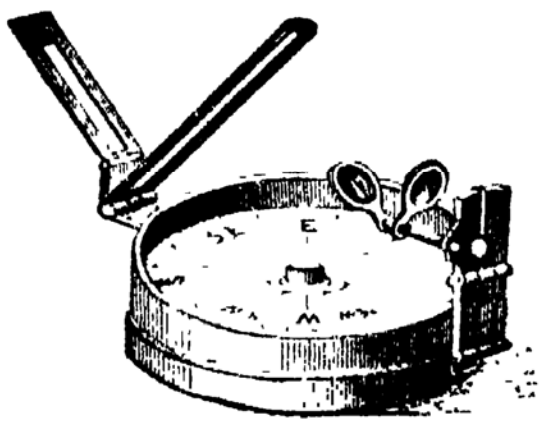

FIG. 22. Azimuth Compass.

Fox's Dip Circle. This instrument, contrived by Robert Fox, is more especially useful for observations at sea. In use it must be placed on a gimbal stand and duly levelled commencing the observation. The following are the peculiarities of this instrument: (1) the needles have two fine pivots or which are inserted into jewelled s; (2) in order to avoid parallax are two graduated circles, the arther from the eye than the and when reading the needle e is to be so placed that precisely the same reading shall be given th circles, the true position of eedle being thus obtained, (3) s a rubber made of bone or ivory ughened, the object of which is a prolongation of the socket on ck of the instrument, the friuch this rubbing causes enabling eedle to find its true position; avoid as much as possible all due to friction and adhesion, tire socked arrangement may be round. The axles of the needle us compelled to be in contact different set of particles. An way of varying the suspension se a magnetic deflecting arrange attached to the back of the atus. Suppose that a reading position of the needle so de- is now taken. Next reverse sition of the deflecting arrangement which is done by turnovable circle attached to this arrangement 180° round; let sition of the needle be again read. On the hypothesis that edle is equally deflected on opposite sides of it, true position se two observations, the mean reading will give the true The principle of the method of observing with this circle is ly the same as that already described for observations on with an ordinary melinometer.

Fox's Intensity Arrangement is merely a modification of that aced by Lloyd, and already described in § 7.[1]

(δ) *Differential Magnetometers and Self Recording Magnetographs.*

In addition to determinations at fixed intervals of time, it is t of much interest and importance to keep a continuous record the magnetic changes which take place at a few selected s. This is accomplished by means of differential magnetos. It is, however, necessary to continue to use absolute ments side by side with differential magnetometers, because tter (with the exception of the declination instrument) are fitted for recording changes of long period, such as the secular es of the horizontal and the vertical force. The reason of this resently be seen.

17. Early in the history of such instruments it was for hourly observations were exceedingly laborious, and attem made to construct a set of self recording magnetometers set of such instruments which were brought into systemat tion were those devised and constructed by the late Charles which have been at continuous work in the Greenwich Ob since 1848. In 1857 John Welch devised a fresh set of s ne instruments, and introduced them into the Kew Obse These, with certain slight modifications, have formed the instruments supplied to a large number of magnetic obse all over the globe.

18. As we cannot conveniently record changes of d differential instrument, changes of vertical force are n stead by a balance or vertical force magnetometer. We h in a differential system, whether adapted to eye observati continuous photographic registration, three instruments, the declination, the horizontal force, and the vertical for netometers or magnetographs as the case may be. T recently constructed instruments are adapted both for phot registration and for eye observation through a telescop advantage of eye observation is that we see what is tak at the very moment of its occurrence, whereas we only ob photographic record some time after the changes to which have actually happened.

We shall therefore describe (α) the three instrument of pattern α adapted to eye observations, (β) the three instrum adapted to continuous registration by photography, (γ) the of determining their scale coefficients, (δ) the [illegible] of de ing the temperature coefficient of the force m

19. *Kew Instruments: The Observations.* In instruments arranged in the relative position Lloyd so as magnetically to interfere with one

rangement by means h these instruments are con- o self recording, be very simple. In fig. 23 ga- flame burning behind a vertical slit and placed end- rder to render its light more intense. The light from nated slit passes through el being reflected mirror of the declination ma the same image of the

slit upon some sensitized paper in the central box. To speak more properly, two images are thrown, one reflected from the upper and movable half and the other from the fixed half of the mirror. The sensitive paper is wrapped round a horizontal cylinder (fig. 27), and the two images are therefore thrown upon different parts of

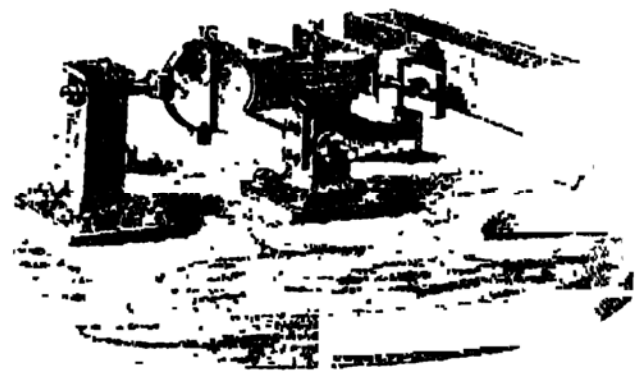

FIG. 26. Vertical Force Magnetometer.

this cylinder. But before reaching the cylinder these two images are by means of a hemicylindrical lens (shown in fig. 27) crushed up into two dots of light. The cylinder moves round regularly by clock-work once in twenty-four hours, and hence the course on the moving paper of the dot of light which comes from the fixed half-mirror will be a straight line, while that of the dot from the moving half mirror will be a curved line depending on the motions of the magnet. When the paper is developed these lines appear black.

The arrangement for the horizontal force instrument is precisely similar to that for the declinometer; for the vertical force it is somewhat different, the illuminated slit being horizontal and not vertical, while the mirror oscillates on a horizontal axis and not on a vertical one, the hemicylindrical lens too and the cylinder are vertical and not horizontal. It was found necessary to put the plane of motion of the vertical force magnet 15° out of the magnetic meridian for the following reason. The axes of the telescopes are respectively 30° inclined to the tubes which go from the magneto-

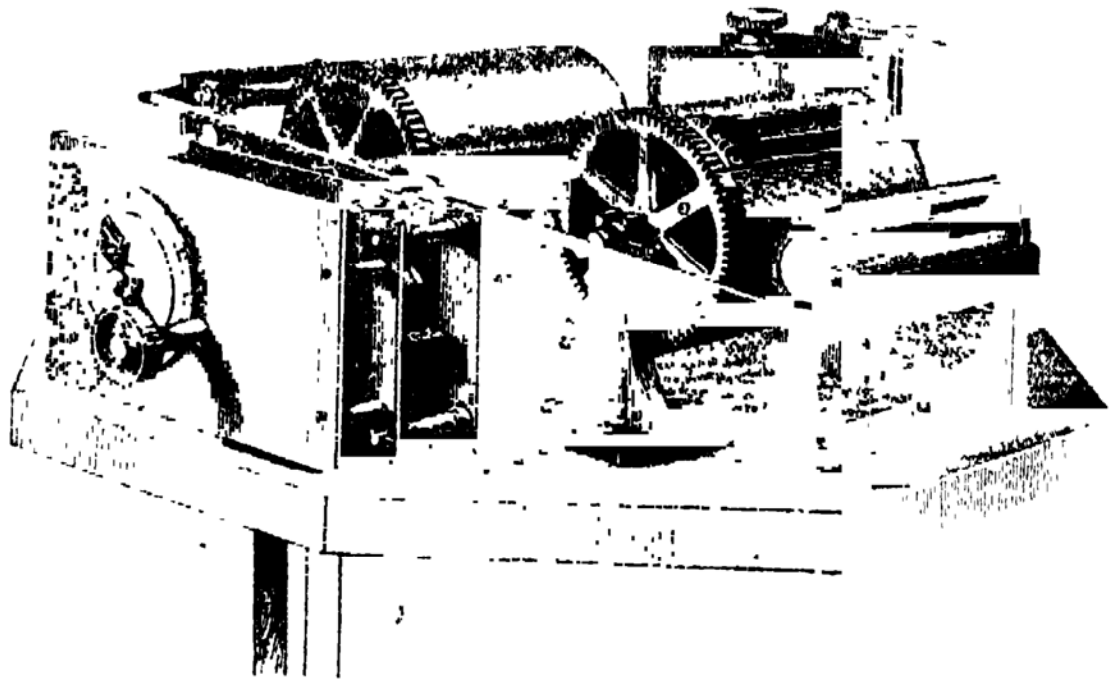

FIG. 27.—Magnetograph.

meters to the central box, and hence had the vertical force magnet swung in the magnetic meridian it would have been necessary to place the mirror inclined at the angle of 15° to the axis of motion of the magnet. This was tried, but it was found that in this position of the mirror the correction for temperature was so excessive that the instrument became a thermometer and not a magnetometer. The mirror was therefore put in a plane passing through the axis of motion of the needle, the needle being made to move in a plane inclined 15° to the magnetic meridian.

22. *Scale Coefficients of Differential Instruments.*—It is necessary to know the value of one division of the scale in the magnetometer or of one inch difference in the ordinate of the curve impressed on the photographic paper in the magnetograph. In the declination instrument it is only necessary to obtain the angular deviation corresponding to one division, and this may be done at once by a series of measurements. In the horizontal and vertical force instruments we wish to obtain the value of one division in parts of force. There is more than one method by which this can be accomplished, but that of John Allan Broun is probably the simplest, and it is, we believe, the one adopted at most of the various observatories possessing self-recording instruments. It is given in the *British Association Reports*, 1859.

23. *Temperature Coefficients of Differential Force Instruments.*—Broun has devoted a great deal of attention to the subject of these coefficients, and has come to the conclusion that the best and most unobjectionable method of determining them is to

e the instrumental readings on days when the tempera
high with the readings on days when the temperature is

By differential instruments the components of a force affect-
magnet are determined in three directions at right angles
h other. It does not, however, follow that this force is
y due to changes in the magnetism of the earth. We know
ertain forces connected with the sun affect the earth's mag-
, and on certain occasions at least these forces manifest them
as currents in the upper regions of the atmosphere and in
st of the earth. Now such currents will have a direct effect
he needle as well as an indirect effect through the changes
they may produce in the magnetism of the earth. The total
ce on the needle will therefore be made up of these two ele-
the one denoting the direct influence on the needle of the
ing force, and the other the indirect influence through the
produced in the earth's magnetism. No attempt has yet
ade to separate the action of these two elements.
Self-recording instruments after the Kew pattern have been
d to observatories at the following places:

atavia.	Mauritius.
oimbra (Portugal).	Kolaba (Bombay).
sbon.	Vienna.
Petersburg.	Zi Ka Wei (China).
orence.	San Fernando (Spain).
onyhurst.	Potsdam.
trecht (declination only).	Brussels.
elbourne.	Nice.

o, Montsouris (Paris), Greenwich, Wilhelmshaven (?), Cape
and Havana (?).
understand that Professor W. G. Adams is at present
d in making a comparison of simultaneous curves from vari-
tions of these lists.[1]

AGNETIC POLES OF THE EARTH—SECULAR VARIATION.

Magnetic Poles of the Earth. In the article MAGNETISM it
n shown that Dr Gilbert of Colchester had at a very early
grasped the important truth that the earth is a magnet, a
which was afterwards mathematically demonstrated by Gauss.
reserved for Halley, the contemporary of Newton, to show
he earth must be regarded as having two poles in the northern
vo poles also in the southern hemisphere, so that, unlike
ry magnets, its magnetic system has four poles altogether
proceeding further it will be desirable to state what it was
alley actually did and what are the conclusions to be derived
is investigations. It has been remarked by Professor Stokes
while in an ordinary bar magnet we may practically regard
le as having a physical reality and as being the cause of well
attractions and repulsions, we are not entitled *a priori* to
that a point of maximum force in a large spherical magnet
e earth must necessarily be the seat of attractions and repul
fter the same manner as the pole of an ordinary bar magnet.
o be determined by observation to what extent the earth
y preserves an analogy to an ordinary magnet. Now Halley's
sions were derived from the pointing of the declination
since in his day there were no observations possible on total
tic force. He argued that there are two points or poles in
rthern hemisphere to which the needle appears to be attracted,
the upper region of America and one above Siberia. So far
nclusion is hardly anything more than a formal one derived
he grouping together of observations. He asserted that these
be as they are known to be if we imagine two such poles or
force each exercising a causal influence on the magnetic
. And the justification of Halley's way of regarding the earth
d in the fact that when force observations came to be made
ch foci of force were actually found to exist. We do not,
er, mean to imply that these foci have causal properties
y similar to the poles of a bar magnet, for this is not the

rder to exhibit the process of reasoning which led Halley to
nclusion, let us first imagine that the earth has only a single
r force-focus in the northern hemisphere, and that this is
dent with its geographical pole; then, assuming that this
as a catsative influence on the needle's declination, we should
all needles to point everywhere due north. If, however, this
e not coincident with the north pole of the earth, let us draw
dian circle passing through the magnetic pole and complete
nd the earth so as to divide the earth into two halves. At all

points in this meridian circle the needle might be expected
due north, while in the one half of the earth so divided
point to the east and in the other half to the west of tru
In the next place let us imagine that the earth has two no
netic poles or foci of equal strength, both being at the same
while their difference in longitude is 180°, and let us draw
plete circle of meridian passing through these poles (fig. 2
us start from a point in this circle under one of these poles and pursue our journey eastwards along a circle of latitude. At first the needle will point due north. As we move eastwards the needle will point westwards to the pole we are leaving until we come to a region half way between the two poles, where it will be equally solicited by each, and will therefore again point due north. Let us call the space we have travelled over since we set out A. As we proceed the needle will now be under the predominant influence of the second pole to our right, and will therefore point to
until we arrive at the meridian under the second pole. Thi
space which we have travelled over let us call B. As we
we pass through a space C where the needle again points to
until being once more equally influenced by the two poles
point due north. After this we pass through a space D of
variation until we arrive once more at the point from w
started.

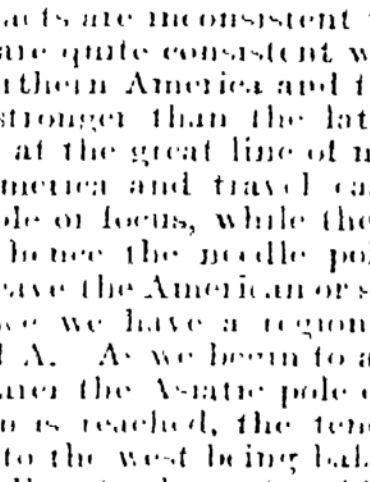

Fig. 28.

Thus there are now four spaces instead of two, and t
shown in fig. 28, where the centre of the circle represents th
geographical pole of the earth, and its circumference the
If pole 2 be inferior in power to pole 1 the spaces B and C
smaller in size than A and D.

27. This fact is an arrangement of things that agrees v
with the results of observation, if we add that the two poles
precisely 180° removed from one another in longitude.
represent lines of equal magnetic variation in 1882. There
lines extending throughout both hemispheres at all points
there is no variation, and also an oval-shaped district
northern hemisphere throughout all points in the circumfe
which we have no variation. These facts are inconsistent
hypothesis of a single pole, but they are quite consistent w
of two poles or foci of force, one in northern America and
in northern Asia, the former being stronger than the lat
order to see this let us take our stand at the great line of n
tion which passes through North America and travel ea
We are just south of the American pole or focus, while the
pole or focus is nearly 180° off, and hence the needle po
north. As we proceed eastwards we leave the American or
pole to the westward of us, and hence we have a region
variation which we have agreed to call A. As we begin to a
the eastern side of Europe we get nearer the Asiatic pole
and at length the line of no variation is reached, the ten
the American pole to pull the needle to the west being bal
the tendency of the Asiatic pole to pull it to the east. A
easterly variation predominates throughout a region B
length we come to a point in the western boundary of the ov
we may imagine ourselves to be directly south of the Asia
while the American pole is nearly 180° distant; once
needle points due north. As we still travel eastwards we
Asiatic pole, which is now the predominant one, to our
hence we have here a region C of westerly declination. A
we come to the eastern boundary of the oval, where the te
the Asiatic pole to pull the needle to the west is balance
tendency of the American or stronger pole (acting now tow
right) to pull it to the east, so that we have once more a
no variation. After this the American pole predominates,
have a large region D of easterly variation until we trav
once more to the point from which we started.

28. This train of argument receives, as we have alre
tioned, corroboration from the fact that in the map of total
power two foci of maximum force, one in northern Am
the other in northern Asia, that in America being the
This evidence was not, however, in existence at the time o
and his hypothesis of two poles does the greater credi
sagacity, inasmuch as he had to deduce it from a compa
small number of observations of declination and dip, those
being altogether wanting.

29. We have hitherto spoken of two poles or, more
foci of maximum force, the positions of which are of co
pointed out in fig. 29; but we have seen that the existenc

[1] We are indebted for the admirable charts given in figs. 29–32 to the
of the hydrographer Captain Sir Frederick Evans, who, in order to
allowed us to make use of the information he had embodied even be
officially published, and who likewise placed his plates at our disposal.

are indebted to Mr Gordon and to his publishers Messrs Sampson Low & Co
o have obtained them for us—for the sketches of the instruments for
determinations, with the exception of that of Kater's compass, for which
ndebted to Mr J. J. Hicks. For the sketch of the self-recording mag-
phs together and in detail we are indebted to the Kew committee and to
f. Whipple, director of the Kew Observatory

first conjectured from the behaviour of the line of
or declination. Now it will be noticed by looking at the
map (fig. 30) that all the lines of equal magnetic variation
converge to a point in the extreme north of the American
nt. This point is not, however, coincident with the chief
force, which lies decidedly to its south, but it is no doubt
nt with the point denoting a dip of 90°, the locality of
which may be inferred from the map of magnetic dip (fig.
it is likewise no doubt coincident with the position of a
horizontal force which may be inferred from the map of ho
force (fig. 33). Thus we have a point to the extreme
America which has the following properties:—(1) the varie
of declination converge to it; (2) the needle points vertical
wards at it; and (3) the horizontal force vanishes at it.

ecular Variation.—The earth then as a magnet must be
d to have two sets of centres of force. We shall next
to show that these centres cannot be regarded as constant
position and intensity.
ould be premised that, while there is no well-established

evidence to show that either the pole of verticity or the ce
force to the north of America has perceptibly changed it
ere is, on the other hand, very strong evid to show t
have a change of place on the part of the Siberian focus and
the part of its analogue in the southern hemisphere.
Table I. (p. 166), given by Gilpin (*Phil. Trans.*, 1806),[1]
the change in the position of the needle in Great Britai

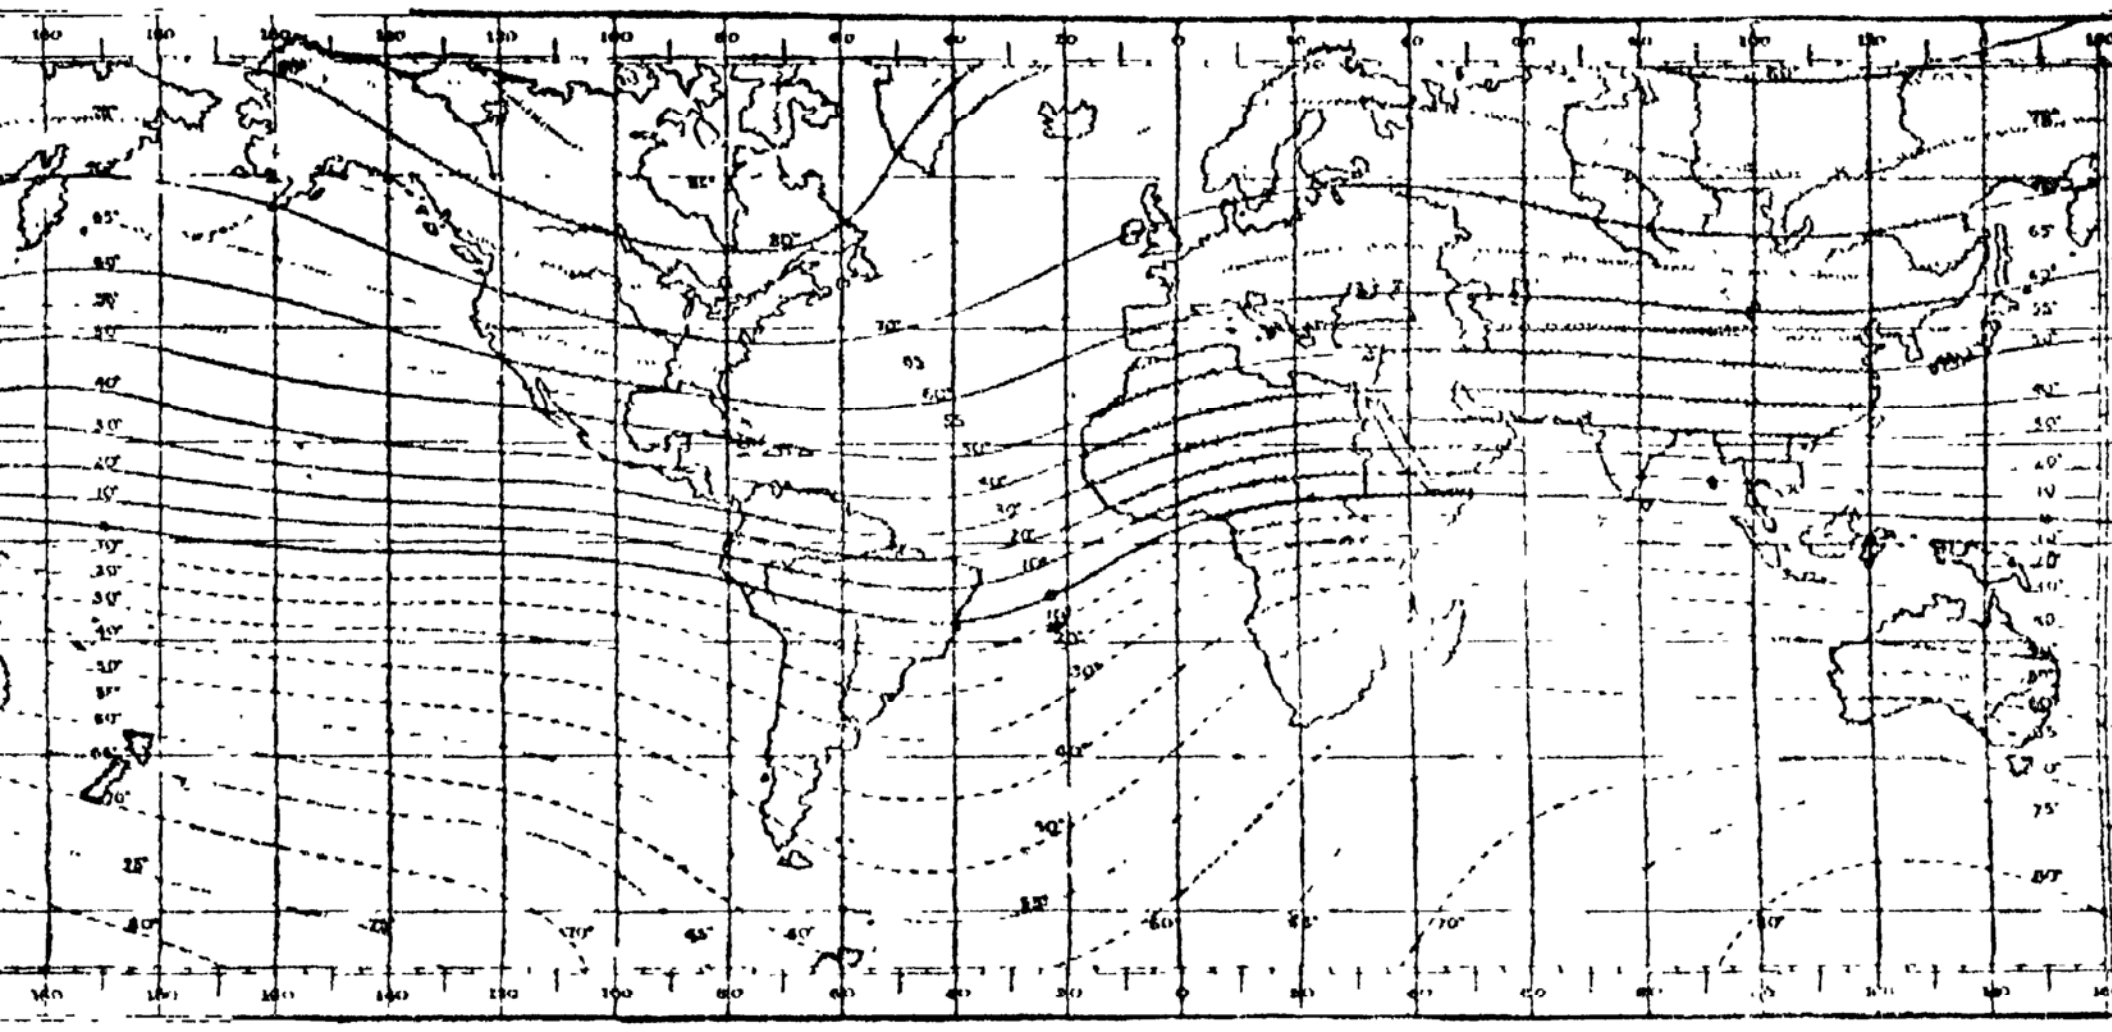

FIG. 31.—Lines of Equal Magnetic Dip, 1882

liest observations up to the beginning of the present

Between the dates recorded in this table the needle has been
g more and more to the west, which implies either a relative
in the power of the American as compared to the Siberian
r a motion of the Siberian focus from west to east. On the
position the lines to the eastward of the Siberian focus

for instance, the line of no variation depending on a balance
it and the American focus should be drawn in towards it,
should travel westwards; but if the latter supposition is
this focus has been moving eastwards while retaining its for
lines to the east of it would be found moving eastwards also.
is strong evidence that the latter is the case, and that
northern hemisphere there has been a long continued proc

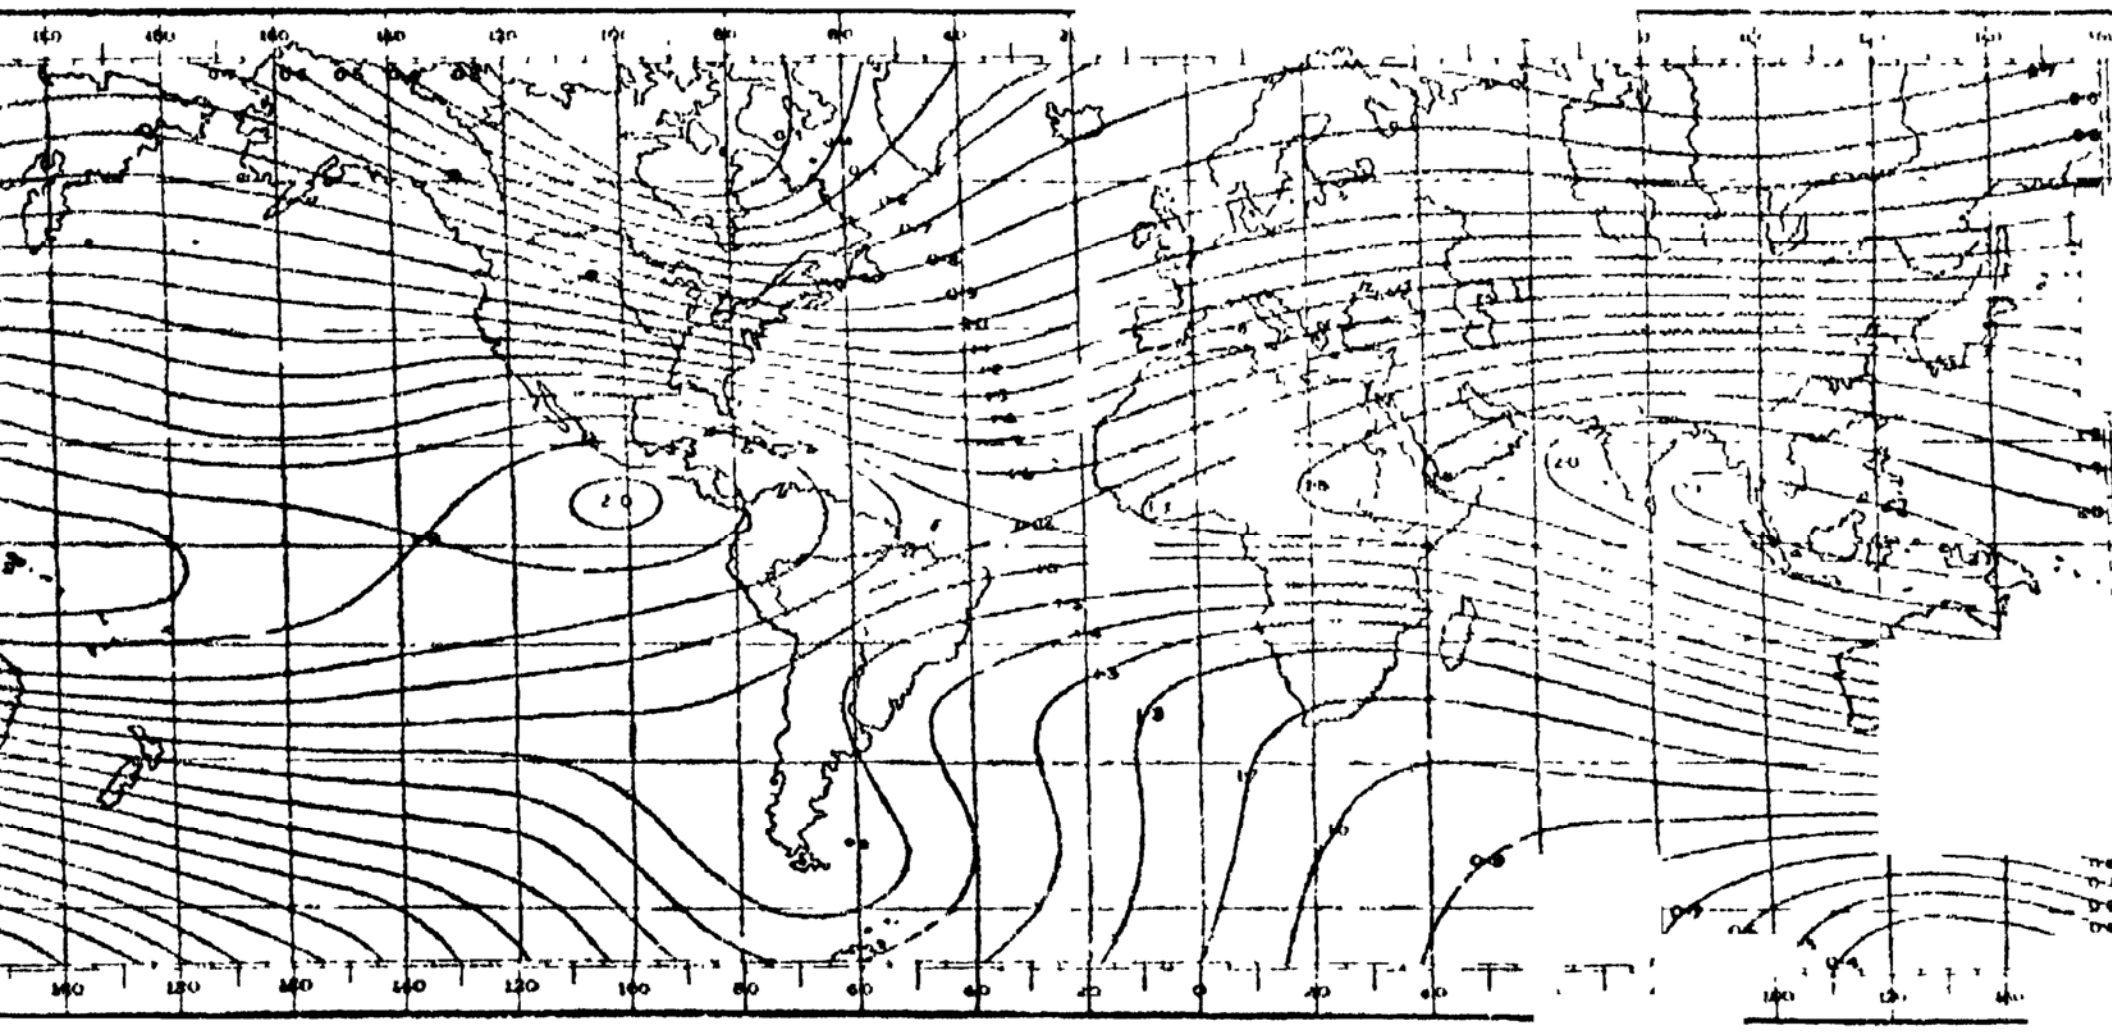

FIG. 32.—Lines of Equal Horizontal Force, 1882.

eastwards of the system of magnetic lines on both sides of
erian focus. In the southern hemisphere also we have proof
e analogous focus has been travelling, not from west to east,
m east to west.
There is some reason to believe that the eastward motion of
erian focus has been recently reversed, and that it is now
from east to west. Table II. shows the declination observed

at Bushey Heath (Herts) during 1817–20, and at Kew fro
to 1882.
It would appear from Table II. that the maximum w
declination was reached in 1818, and that the needle has su
date been travelling eastwards. A similar change has tak

[1] Taken from Walker's *Magnetism*

stations; and, although these changes are not strictly neous at the various stations, they have yet been sufficiently and near together in point of time to indicate that some change has probably taken place in the movement of one s magnetic foci of force.

33. Halley sought to explain the four-pole theory and to

e secular change by imagining a solid globe or *terella*,[1] con-
c with the earth but rotating independently of the external
and having a slightly different period of rotation, the shell
g two poles and the terella two others. While continuing to
e Halley's sagacity, we shall not now be disposed to allow such
stitution of the interior of the earth, but will rather be led to
o some external influence as the cause of the secular variation
ile we have strong evidence that the Siberian focus has changed
sition, we cannot assert that the American focus has been
ately stationary, or that neither focus has experienced any
ges of force. On these points we must be content to be guided
servation alone.

It has been supposed by some magnetician that it is possible
mpute with something like certainty the particulars of the
ns of the magnetic foci. Hansteen more especially (1811 19
uted both the geographical positions and probable periods of
ution of this dual system of foci of force round the terrestrial
Sir Frederick Evans has discussed in connexion with the ob-
ll the most recent observations,' and points out two objections
y such theory as that of Hansteen, viz., (1) that, while a mag
turning point has been reached in certain regions, there are
portions of the earth in which this change has not yet been
plished, and (2) that in certain districts of the earth very great
ges in force have taken place. "If we turn," he says, "to the
ent of South America and its adjacent seas, we shall find a
ution of the intensity of the earth's force now going on in a
kable degree. An examination of the [illegible]t observati
by the 'Challenger' officers at Valparaiso and Monte Video,
ared with those made by preceding observers, shows that
n half a century the whole force has respectively diminished
xth and one-seventh, at the Falkland Islands one ninth."
e whole, while there is strong evidence that the Siberian focus
ntil recently been travelling eastwards, and its analogue west
, and evidence less conclusive that recently a turning point in
notion has been reached, we are disposed to think with Sir
rick Evans that a formal theory like that of Hansteen does not
with recent observations. We shall revert to this subject
In Tables III. and IV. certain yearly values of declination,
nd horizontal force are given for various stations.

Inequalities in or connected with Terrestrial Magnetism depending on the Sun.

As there is a marked likeness between the ways in which the
ominates over the two great divisions of terrestrial phenomena,
rology and magnetism, let us endeavour to describe the
effect upon the latter by referring to its influence on the
r, the chief peculiarities of which are well known to all We
hat the temperature of the air at a given station is subject to
rnal fluctuation having its minimum value shortly before sun
nd its maximum early in the afternoon. We find likewise
he mean temperature for the day, as well as the amplitude of
iurnal oscillation, depends upon the season of the year, both
greatest about midsummer and least about midwinter. Now,
s were the only manifestation of solar influence upon this
ular element, it would be possible to predict the temperature
y hour of any day once the mean temperature, the diurnal
ion of temperature, and the modification of these for different
s of the year had been well ascertained. But this amount of
arity is very far from taking place, the march of temperature
frequently interrupted, cloaked, perhaps even reversed, by
dvent of peculiar weather. Thus we may have very cold
er in midsummer and very warm weather in midwinter, or
ay have a very cold afternoon and a very warm early morning,
hich means the ordinary conditions of temperature will be
letely reversed. In like manner weather interferes even to a
r extent with the diurnal oscillation of the atmospheric
ure, so that, in British latitudes at least, it is only possible to
o this correctly by means of a long series of observations.
eather, however, does not consist of a perfectly lawless inter-
re with periodical phenomena, but is subject to laws of its own,
of which we are beginning to discover. Sometimes weather
exalt or depress the diurnal fluctuation of temperature without
wise affecting its character; but sometimes too the turning-
s and the general appearance of this fluctuation are greatly
nced by peculiar weather.

Now it is believed that we have something of the kind in
fluctuations depending on the sun to which the elements of
strial magnetism are subject. Let us take the declination
e most easily studied of the three magnetic elements, and
ose that we are engaged in considering the traces denoting the
uations of declination as derived from a set of self-recording
netographs in Great Britain. Here we shall at once be able to
nize in an unmistakable manner the diurnal variation depend-
upon the position of the sun, in virtue of which a freely-

suspended magnetic needle reaches the easterly extreme of
about eight in the morning, and the westerly about two
afternoon. We shall likewise perceive that the range
diurnal fluctuation is greatest at midsummer and least
winter. In fine, the characteristics of this fluctuation, de
as they do upon the hour of the day and the season of t
are not very different from those exhibited in the diurnal
tion of atmospheric temperature. But, however thoron
may have ascertained the mean declination and its diurnal
tion, as well as the modifications of these depending on th
of the year, we shall nevertheless find it impossible to pre
exact position of a freely-suspended magnet at any mom
particular day. Here then too we have something which
called magnetic weather, and which interferes with the
progress of the systematic fluctuations of the magnet. M
weather has, like its meteorological analogue, a set o
own, some of which we are beginning to find out.
magnetic weather may exalt or depress the diurnal fluctu
declination without affecting its character, but it is imagi
at other times the turning points and general appearance
fluctuation may be greatly influenced by peculiar magnetic

38. There is, however, a kind of magnetic change whi
a- we know at present, is not analogous to anything in mete
and introduces an additional element of complexity in any
to analyse the fluctuations of terrestrial magnetism. We
known magnetic disturbances or storms which occur
only in places very widely apart. Under these circum
it becomes a question how we can best deal in a practical
with this complicated system of things.

We do not think that with our present knowledge an
system can be adopted than that first introduced by Sir
Sabine in his discussion of the results of the colonial
observatories. Suppose that we have hourly magnetic obse
at a station, then first of all we should arrange these into
groups each hour by itself. We should then reject as d
observations all those which differ by mo[illegible]ertain
from their respective normals of the [illegible]th and ho
normals being the hourly means in each month after the
of all the disturbed observations. This method enables u
exclusion of disturbance, to ascertain with much accuracy
form of the solar-diurnal variation of the magnetic elem
given place corresponding to every month of every year,
only that the observations are sufficiently numerous. On t
hand it will probably fail in accurately giving [illegible]e the variati
day to day of the [illegible] of the solar-diurnal fluctuations caus
advent of peculiar magnetic weather, inasmuch as the r
the extreme effects of such weather will probably be cut
the undisturbed observations and reckoned among the distu

For instance, it is known that the solar influence on te
magnetism varies from year to year, and it is suspected th
are also short period fluctuations of solar influence. It wo
however, be a safe proceeding to attempt to estimate num
the last mentioned element of fluctuation by taking the s
diurnal ranges of those observations at any station, rec
undisturbed, by the above process, and plotting them as s
ordinates of a curve, and then supposing that this curve wo
us a true graph[illegible]ors[illegible]entation of solar changes. I
rather p[illegible]y represent such changes with the top and
the [illegible]fluctuations cut off. But if the undisturbed
tion is in this respect we can hardly be wrong in suppo
there has been eliminated from the mean as far as possible, all
due to magnetic storms, and hence that they will afford us
better means of estimating small fluctuations, such, for ins
those due to [illegible]noon, than we could have had without th

Finally, with [illegible]gard to that portion of the observations
as disturbed, we are probably not certain that every such
tion represents a true disturbance, or that the absolute
occurrence of the various observations selected at a disturb
station will be the same as the [illegible]at another. Neverth
Edward Sabine has shown that at the Kew Observatory cer
of disturbance deduced from the whole body of observations
as disturbed are closely reproduced when this selection is
a narrower limit[illegible]ninety five days of prominent disturbar
alone taken. With these prefatory remarks we shall now
to discuss the diurnal inequality of terrestrial magnetism.

39. *Total Diurnal Inequality Defined.* It will be see
on that disturbed as well as undisturbed observations are s
a diurnal variation, but these two variations are different
name *diurnal inequality* is generally given to the compou
tion which is the joint resultant of the two. *Solar
variation* is that portion of the compound inequality wh
to undisturbed observations, while that which refers to
ances has received the name of *disturbance-diurnal varia
would appear that in the United Kingdom, and perhaps
out Europe, the total diurnal inequality is not very
different either in character or range from its most i
component the solar-diurnal variation, at least so fa

[1] See Walker's *Terrestrial and Cosmical Magnetism*, where the subject is well discussed.

[2] His lecture to the Royal Geographical Society, March 11, 1878

ation is concerned. When the diurnal oscillation of a freely-
ded magnet was first observed, the subject of magnetic
ances was not understood, and the early individual deter-
ons which have been handed down to us are not such as to
the expenditure of any very great labour upon them for
rpose of separating the disturbed from the undisturbed observ-
s. Inasmuch, however, as the total diurnal inequality of
ation (which is in reality the element given by these early
ation) does not greatly differ from the solar diurnal varia-
may with much justice and little risk of error give the
of these early observations in connection with that of the
diurnal variation of declination which is by far the best
and perhaps the most trustworthy of all the various magnetic
produced by solar influence.

Solar Diurnal Declination Curve.—Graham, an instrument
maker of London, found in 1722 that a freely suspended
magnetic needle subject to the ordinary oscillation of definite char-
The next observer was Canton, who in 1759 became acquainted
with four thousand observations which he communicated to the
Society on December 10, 1761, and from which he concludes
the range of the diurnal variation is greater in summer than in
Macdonald observed at Fort Marlborough in Sumatra
(*Phil. Trans.* 1820), and Duperrey in the tropics in 1822–
perhaps the first that might lead us to conclude that the
ude of the diurnal oscillations of the needle is less in the
than in middle latitudes, and that the motion of the needle
southern hemisphere is in the opposite direction to that in
it moves in the northern hemisphere at the same hour.

Solar Annual Inequality.—The existence of these early
ations had long been pointed prematurely to conjecture
ere must be a time somewhere near the equator when
no horizontal variation in declination. In 1847 Sabine com-
nicated to the Royal Society the results of five years' observations
Ireland, showing that at that station for the half of the year
ning at the vernal and reckoning at the autumnal equinox the
of the needle corresponded nearly to that in the northern
sphere, while for the other half it corresponded nearly to that in
the southern hemisphere. Sabine's views confirmed and extended
been used to reduce the annual inequality by discovering the
ntation of the various colonial magnetic observatories. More
y, the result of twelve years' observations at Trevandrum,
servatory established by the Rajah of Travancore, John
Broun gave in a very complete form the law of change
the diurnal variation of magnetic declination near the
, showing the extinction of the mean movement near the

Perhaps the best way of contributing what really takes place is
examine which is that adopted by Sabine.
the annual value of the solar diurnal variation is of what
calls the northerly type in place of middle latitude in the
n hemisphere, and of what may be called the southerly type
of middle latitude in the southern hemisphere. Now let
a northern station, and consider the mean form of its solar
variation for the six months beginning with the vernal
Here we shall have an oscillation of the northerly type
more greater than the annual range. For the other six months,
, we may imagine that the annual range is supplied
by the superposition upon it of a variation with a type similar
with. At the same station during the other six months, the
nual variations will be taken from the mean of the year, as if the
variation had been depressed by the superposition on it of a
on with a type the opposite of its own, that is to say, with a
ly type. At a station in the southern hemisphere, again,
an annual form of the solar diurnal oscillation is of the
ly type, we have during the six months beginning with the
approximately by the superposition of a variation of northerly
ype upon it during the other six months it is depressed by the super-
position of a southerly type. Thus when the sun is
of the equator we have superposed variation of the northerly
on both hemispheres with the effect of increasing the range
northern hemisphere and diminishing it in the southern;
the sun is south of the equator we may superpose a varia-
the southern type upon both hemispheres with the effect of
ishing the range in the northern and increasing it in the
n hemisphere.

the equator, as at Trevandrum where Broun made his
ions, we find the mean annual value of the solar diurnal
n to be extremely small, if not altogether evanescent.
the six months beginning with the vernal equinox the type
ly northerly, while for the remaining six months of the year
rely southerly in character. In fine, at this station the
rnal variation changes its character at the equinoxes, at
me we have, as already observed, an extinction of the mean
nt, not indeed in absence of all variation, but rather a

alker, *Terrestrial and Cosmical Magnetism*.
s the name used by Sabine, but its appropriateness may perhaps be
d.

variation having an undecided character, which for a few da
be of one type and then of the very opposite. There is mov
but no mean movement.

43. In the following table (V.) the solar-diurnal varia
given for Kew, Trevandrum, and Hobart Town. Of
places the first denotes a station in middle latitude (n
hemisphere), the second an equatorial station, and the
station in middle latitude (southern hemisphere).

this table a... te reckoned positive, d...
ds magnetic ...st negative. The scale is in minutes of arc.

Also in fig. 33 we have a graphical representation of the
diurnal variation for the whole year at these three station
which it will be seen that the range at Trevandrum is ext
small, and that the curve for Hobart Town is opposite in appe
to that at Kew.

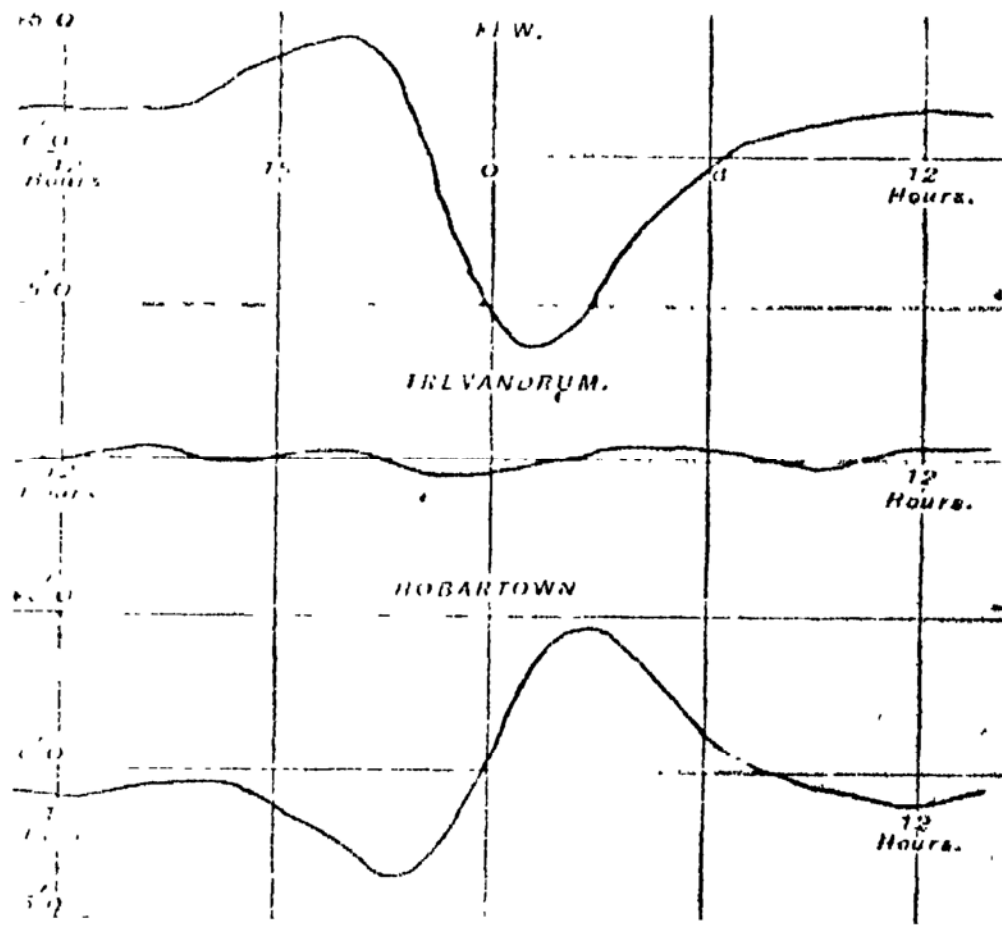

Fig. 33.

Finally, in fig. 34 we have a graphical representation of the
annual inequality or difference from the whole year's mean of t
half yearly means of Table V., the one half-year (that with
lines) commencing at the vernal and the other at the aut
equinox. It will be seen from this figure that the semi
inequality is of the same character in both hemispheres, the li
extending even to its minor peculiarities.

44. *Change from Month to Month.*—Charles Chambers, di
of the Kolaba Observatory, Bombay, remarks (*Trans. Roy.*
December 10, 1868) that "the regular progression from
to month in the diurnal variation is so distinctly shown i
Bombay observations as to lead, on a first inspection, t
supposition that the law of variation is identical throughou
year, the extent only (including a reversal of direction) varying
month to month. But in this respect a different exposition
character of the variation in different months shows tha
first thought would be inaccurate." He then proceeds to d

h the monthly val of the solar diurnal variation at
. Broun for Trevandrum observations discuss
the solar diurnal variation at the Trevandrum Observa
t would hardly be of service to reproduce here the result
discussions, but when such analyses become sufficiently

harbour near the Magnetic Pole. Figs. 33 and 34 exhibit
prominent feature of the solar diurnal variation of declina
he extra tropical regions of the northern hemisphere. If
ver stand over the centre of the needle and look towards
ed end, or that which points to the north, he will perceive
towards his right hand which will reach its
nd a deflexion towards his left hand which will reach its
about 2 P.M. But are these deflexions to the right and
l of geographical or of magnetical north? The question
answered by Sabine in his discussion of the results of hourly
ions of the magnetic declination at Port Kennedy (*Phil.
1863, p. 660*). This station is 72° 6′ 49″ W. Lat. and 94° 19′
, and here the marked end of the needle, while it points
the magnetic pole points in reality about 35° to the west of
Now the marked end of the needle when viewed at S.A.M.
Port Kennedy is seen to have moved to the geographical west
he magnetical east. It would thus seem that throughout
a-tropical regions of the northern hemisphere the S.A.M.
of the needle is always towards the magnetic east but not
owards the geographical east, while the deflexion at 2 P.M.
ays tend towards the magnetical west but not always
the geographical west. In time the oscillations have
refe the pe l and
north geographical pole. No observations o tained
made in the southern hemisphere.

16. *Long Period Inequalities at Declination Kew.*—It w
observed by Lamont that the yearly values of the diurnal
in the declination at Munich presented signs of a per
variation. In 1852 Sabine (*Phil. Trans.*, 1852, p. 103)
that this inequality corresponded in period with the
cies of black the surface of the s

The existence of black-spots or the dark of the sun w
known to the Chinese. In Europe they were but rarely
observed after the invention of the telescope, and it was
from their behaviour that the sun revolved about its axi
twenty-six days. Hofrath Schwabe of Dessau, from a long
forty year observations of the sun was the first to show
state of the sun's surface as to the spots was not uniform,
their frequency was subject to an inequality the average p
which was about eleven years. Other inequalities both
and shorter periods have been supposed to exist, but the
yearly period is the most prominent and is to be carefully
the sun spot catalogue of Schwabe is the best with respect
completeness, yet Professor Rudolf Wolf has endeavoured t
observations of sun spots made at different times and by
observers compare with each other, and by forming what
ing approximately the relative number of sun spots for ea
The list extends back into the 17th century, and is of gr
in confirming past all doubt the existence of the eleven yea
It will appear below that the sun is probably to be reg
viewed most light and heat at those times when sun
most frequent. The most accurate and now universally
method of estimating sun spots is to take the spotted area
millionths of the visible hemisphere.

To return from this digression, the correspondence betw
spots and declination range as detected by Sabine was of such
that years of large declination range accord with those of m
spots, and *vice versâ*. In the same year with Sabine (1
Rudolf Wolf and M. Gautier independently remarked the ex
cidence. Subsequent discussions have entirely confirmed
of the connexion, and in May 1872 William Ellis (*Phil.
1880, p. 419*) showed that the observations made at the G
Observatory during the years 1841–77 indicated a relation
nature between the diurnal range of horizontal force as well
of magnetic declination on the one hand and the amount of
frequency on the other. The general character of this con
between sun-spot frequency and declination range is s
graphically in fig. 39 below.

17. *Ratios of Range in Years of Maximum and Years
mum Sun-Spot Frequency.*—Broun (*Trans. Roy. Soc. of Ed
xxvi. p. 1*) has shown that the ratio of the diurnal range of de
in years of maximum to that in years of minimum
frequency for places widely apart on the surface of the earth
nearly alike. This will be seen from the following table:

TABLE VII. *Ratios of Declination Range in Years of M
and of Minimum Sun-Spot Frequency*

Place	Mean Ratio (1)	
Paris	1·71	Capocci and Arago.
Gottingen	1·74	Gauss.
Munich	1·66	Lamont.

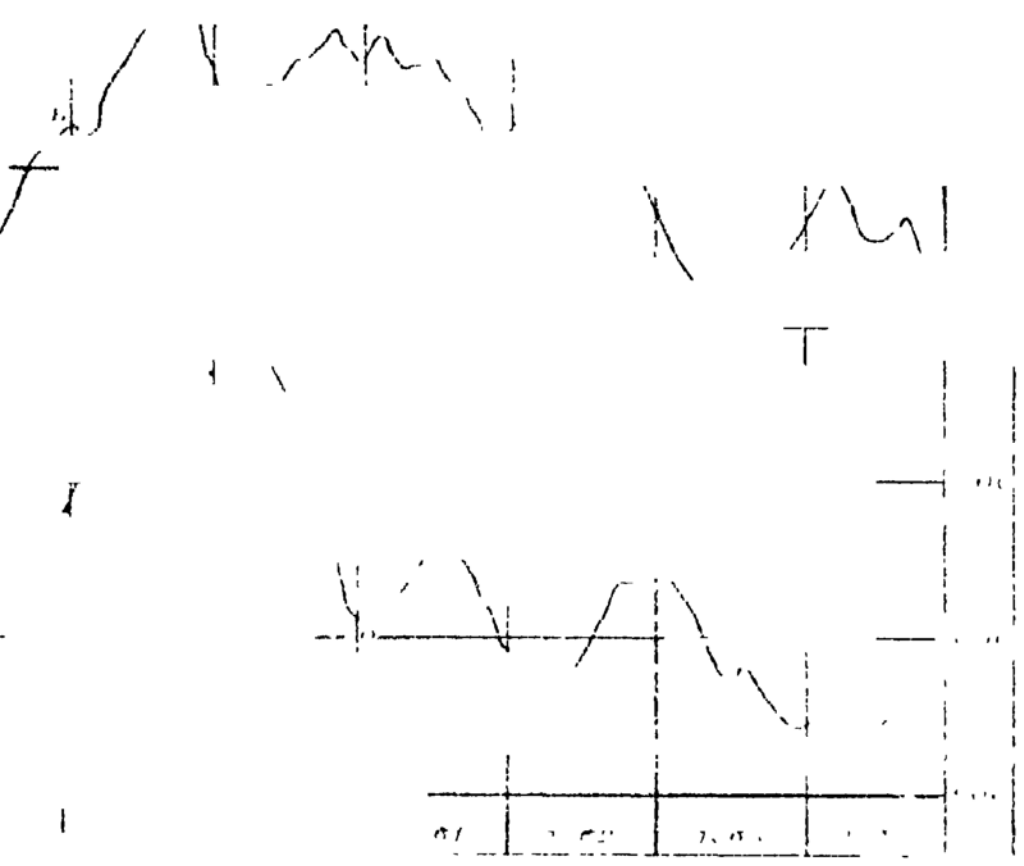
Hobart Town.		
Toronto	1·51	Youngchu Land and L
Trevandrum		

18. *Closeness of Correspondence. Lagging behind of
Stewart has shown (in addition to the declination r
Kew, Trevandrum and Pekin (*Proc. Roy. Soc.*, March 5
February 5, 1874; May 16, 1878) that the correspondence
the rate of the sun's surface and the diurnal range of de
extends to inequalities of short periods as well as to that
the period approximately eleven years, but that a portion
of the surface precedes in point of time that of the de
range. Dr. Lamont pointed out, in time, that the solar cau
the terrestrial effect which latter lags behind to an extent
sometimes considerable. The above conclusions have been cont
Lit. *ut supra*), and have likewise been extended by him
horizontal force. The close nature of the correspondence
and the lagging behind of the terrestrial magnetic effect, wi
from fig. 35.

There are indications that this lagging behind of the
effect is greater for sun-spot inequalities of long than for
short period, a method of behaviour quite similar to what
in meteorological phenomena.

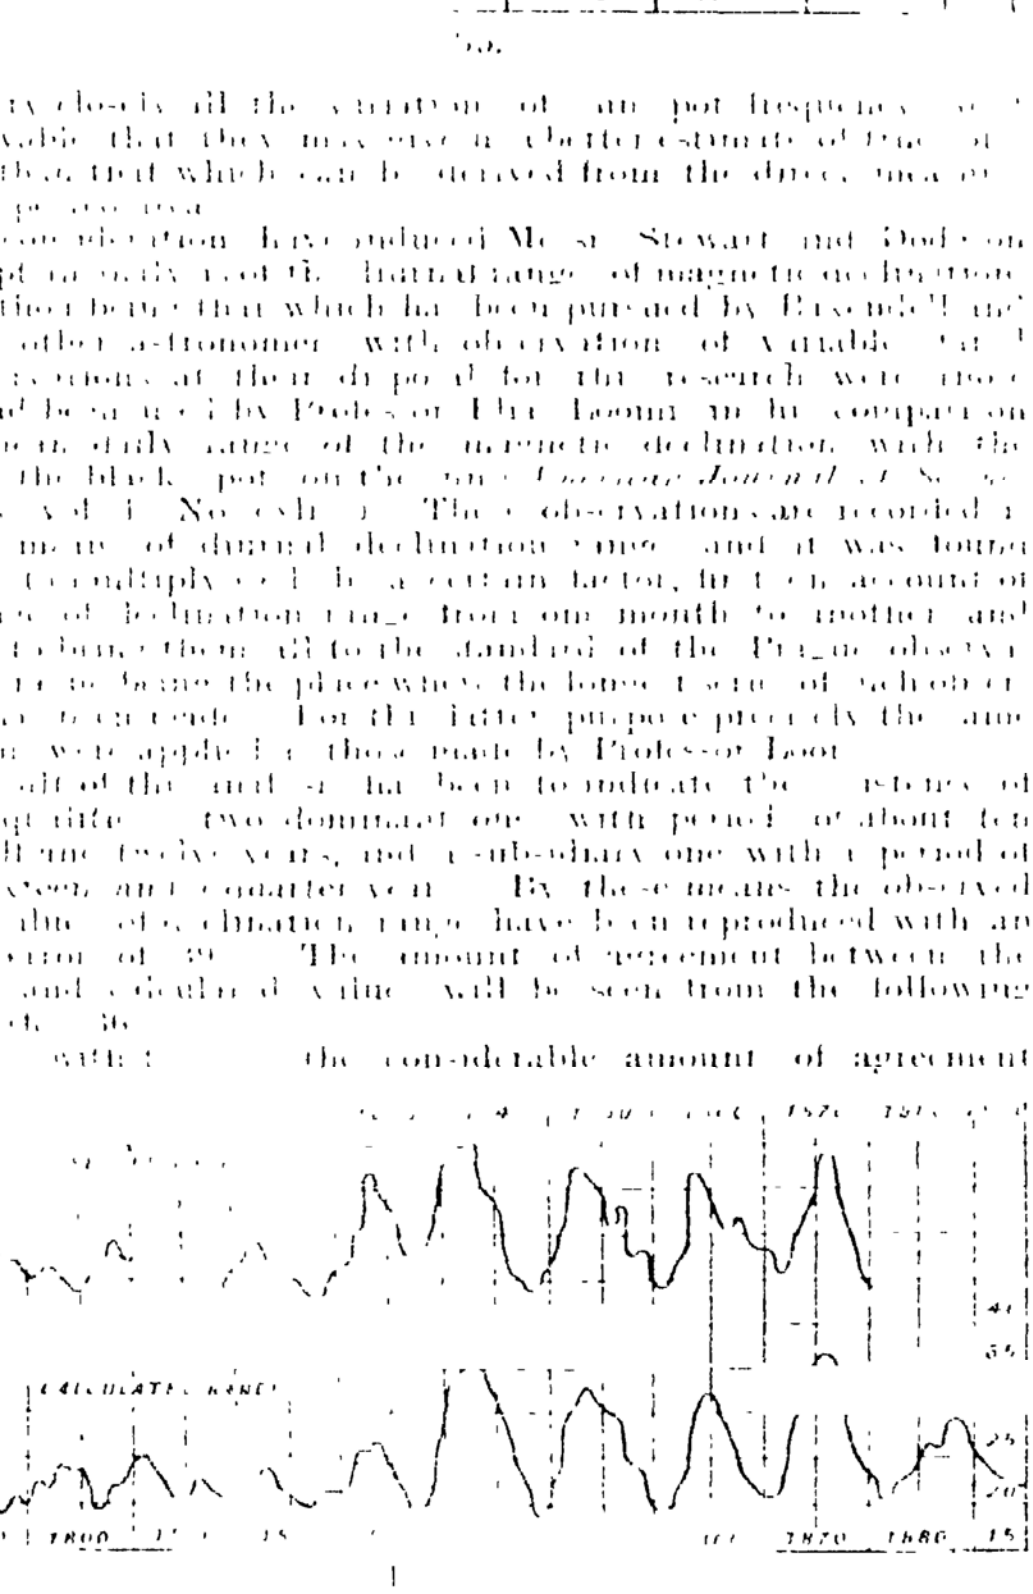
19. *Analysis of Long-Period Inequalities.*—We possess no

recently accurate for a discussion, or a complete account of
relating to solar periodicity before the time when Schwabe
his method the system of solar observations which was
the year 1 . We have, however, a much longer series
annual range of magnetic declination which we have access to



closely all the variations of our present
able that they may give a better estimate of true
than that which can be derived from the direct means
present

consideration have induced Messrs Stewart and Dodson
to carefully reduce the diurnal range of magnetic declination
this being that which has been pursued by Ellicott and
other astronomers with observations of variable
stations at their disposal for the research were more
be surpassed by Professor Elias Loomis in his comparison
yearly range of the magnetic declination with the
the black spots on the sun (*American Journal of Sc*
vol i November) The observations are recorded
means of diurnal declination ranges and it was found
to multiply each by a certain factor, in each account of
of declination range from one month to another and
to bring them all to the standard of the Prague observ
to be the place where the longest series of observ
extended For the latter purpose precisely the same
were applied as those made by Professor Loomis
all of the analysis has been to indicate the existence of
quite two dominant ones with periods of about ten
nine twelve years, and a subordinate one with a period of
seven and a quarter years By these means the observed
diurnal declination ranges have been reproduced with an
error of 3 The amount of agreement between the
and calculated values will be seen from the following
table 36



with the considerable amount of agreement
the results of observ
hardness, it would
obtainable is too short to render the analysis a very
one It will certainly not be necessary carrying back forty
years beyond its starting point, which was in 1784, and
be very hazardous to carry it forward any considerable length into the future It will be seen that cal
indicate a maximum of declination range about 1884, bu
pronounced a maximum as that of 1871 Here then we
prediction which observation will either fulfil or contradict
a practical test of the value of the analysis

51 The remark now made would seem at first sight t
that we are not yet furnished with sufficient yearly records
declination range or of accurate and not observations too
to unravel the long period solar inequality with such comp
as to carry out calculations more than a very short distan
the future with any chance of success and that we may
wait for another hundred years observations before we are
do so On reflection, however, it would seem that lon
inequalities may be caused by the superposition of those
period and that the results of the latter may lead to
the former It would relieve us if this were found to be t
for the observations at our disposal may be sufficient to e
completely a short period the position, amplitude
have in each the elements of a true periodicity

A remark made by the author of the above analysis wou
to indicate that a connection of the returns between long a
period does in all probability exist It is a well known f
the so called eleven yearly variation of declination range
certain time later and at other than mean Thus, for
they have been later for the last forty years but they we
about the earlier part of the present century Now it is cl
an inspection of the observations so far as to trace a corre
oscillations accompanied with an acceleration of the long
time between successive phases, what seems to small os

compared with the dependence of the same The res
long period curve of the sun's spot period, so to
the eleven yearly inequality

Now a phenomenon precisely in the connexi
longer period It we take inequalities in period of thre
month we find that such are often developed or
ten and badly developed or of small range, and that
ence of such accompanied with an alteration of the bas
a of average efficiency, while a small range is accompani
a deficiency of the same The result is a curve of the base
which the period is roughly speaking eleven years May
therefore imagine that the so called eleven yearly period, or,
more correctly, the ten and a half and twelve yearly perio
which the eleven yearly period may perhaps be analysed
more duly beat period for longer disturbance Is it no
more possible that a study of these longer periods may
information regarding the nature of the eleven yearly
whether for sun spots or declination ranges, which the sma
of actual observations is incompetent to afford

and Point Barrow it is the easterly disturbance which
the single progression, while, on the other hand, at Pekin
Nertchinsk, stations which are oppositely related to the
magnetic centre, it is the westerly disturbance which is
mined by Sabine and others that this peculiarity is due
to the fact that Kew and the associated stations may be re
on one side, and Pekin and Nertchinsk on the other, of the
the movable magnetic system.

Sabine has likewise remarked that the rapid progression
which is denoting easterly disturbances, exhibited
which take place not far from the one o'clock time. W
observations plotted all the left-hand curves accurately to Ke
but the curves readily, on account of small irregularities w
curve pendulum-like exhibit. It will be noticed that there
marked resemblance between the maximum at Kew, Toronto
at Nertchinsk, but that the maximum at Port Kennedy and
Barrow, which both occur nearly about the same time, fall a
accurately if not very greatly different from that of the
maximum. Indeed the time of maximum for Port Kenne
Point Barrow is not far from the time of minimum for th
station. Now it has been noticed by Sabine that Port K
and Point Barrow may be regarded as on one side of the M
magnetic centre of rotation, while Toronto and the as
associated stations are on the other side. It seems therefore pro
to connect this fact together with the latter, as the time of ma
Sabine has likewise remarked that the ... mounts
disturbance is much greater at Point Barrow than at
stations. Now from Barrow's observations that perturb
maximum. This and the phenomena above described
that somewhat corresponds to Asiatic perturb
somewhat, perhaps, of the Asiatic pole, and
the centre of minor activity. Sabine, who
appears to have very well appreciated the
these phenomena to the Asiatic pole. He

TABLE VIII

Easterly Range	Westerly Range	Westerly Range

tions of short period hitherto discussed are not necessarily accompanied by a permanent change of mean position of the needle. We have now to inquire whether there be any fluctuation of long period (besides the secular change discussed in §§ 30-33) tending

us at once to the annual variation, for one must look to the later made and more accurate observations in which all possible sources of error have been carefully eliminated. Broun has made an exhaustive experimental inquiry into the several sources of error which could possibly influence his declination needle at Trevandrum. His conclusion was that the variations of torsion of a well-made thread are not sufficient to produce a sensible effect upon the position of a powerful magnet. In fact Grubb's magnet, weighing 6000 grains, and Adie's, weighing 1100 grains, give almost identical results. We may extend the conclusions to other observatories where well-devised instruments have been established, and look with much confidence to such instruments registering correctly the secular as well as the annual change of declination that may be taking place at each locality.

65. The following table (XIII.), borrowed, with the exception of the Trevandrum and Bombay results, from E. Wallen's *Terrestrial Magnetism*, shows the annual variation of declination:

	Declination, Secular Change	Annual Change	Observations Year
Kew	21° 29′ W.	+ 9′·00	1858
Hobart Town	9° 36′ E.	+ 1° 23′·30 W.	1841-45
St. Helena	24° 25′ W.	+ 7′·00 W.	1841-49
The Cape	29° 1′ W.	+ 0° 2′·30 W.	1841-46
	1° 0′ W.	+ 1′·42 W.	1845-?
	0° 22′ E.	+ 1′·?	1841-?
	0° 31′ E.	+ 3′·16 E.	1857-6

PLATE XIV. *Showing the Mean Diurnal Curve for Month of the Year at Seven Stations.*

May	11·8	9				3·7	16·3
June	20·6	17·4	1	6·4	24·1	3·2	9·8
July	7·3	12·6	+ 8·4	3·9	5·6	3·9	1·4
August	20·7	1	5	+ 6·8	1·3	2	1·6
September	9·2	+ 17·1	19·8	13·2	4·1	10·3	+ 0·1
October	19·6	+ 6·0	1·8	1·8	+ 1·6	8·0	11·1	8
November	3·8	+ 9·6	3·3	+ 3·2	2·6	1·2	2·0	1
December	+ 9·6	+ 19·8	+ 2·3	+ 12·6	+ 3·3		4·3	1·8
January	+ 9·6	+ 4·2	3·0	+ 2·9·1	+ 2·2·9	7·1	+ 3·2	1·0
February	+ 34·2	+ 0·6	+ 18·0	6·3	+ 7·9	+ 3·5	2·6	+
March		5	1·0		16·2	1·9	1·2	

Here + indicates that the mean of pole of the needle is to the west and − that it is to the east of its mean position for the year.

66. To cancel the irregularities of the table let us take the means from April to September and from October to March, the former embracing the months around the June solstice and the latter those around the December solstice (Table XV.):

	Mean from April to September	Mean from October to March
Kew		+ 4·5
Toronto	+ 4·?	+ 17·1
St. Helena		+ 6·3
Cape of Good Hope		+ 3·9
Hobart Town	+ 18·7	+ 17·3
Trevandrum	+ 0·1	− 1·6
Bombay		6·?

It will be seen from the above that the means for Trevandrum and Bombay present opposite signs to those for the other stations. The whole amount for Trevandrum is no doubt very small, but Chambers does not regard the evidence for Bombay as conclusive, but on the whole it would appear that two observatories near one another present evidence of a similar behaviour in declination, and we are therefore disposed to regard it as a reality.

67. *Semi-annual Variation of Declination.* If we look at the numbers of Table XIV., we shall see that there are traces of turning points at the equinoxes. Let us, in order to exhibit this, compare together the sums for the six months grouped around the two equinoxes with those for the six months grouped around the two solstices, that is to say, compare the sums for February, March, April, August, September, October, with those for November, December, January, May, June, July; and we thus obtain the following table (XVI.):

	Sums around Equinoctial Months	
		101·2
		96·4
Hobart Town		0·?
Trevandrum		19·0
Bombay		6·2

68. *Diurnal Variation of the Horizontal and Vertical Components of Magnetic Force.* Although self-recording magnetographs have been established in many observatories throughout the world, owing to the peculiar difficulties of the task, and the labour of reduction, very little has been done towards investigating the solar diurnal variation of the horizontal and vertical components of the earth's magnetic force. Señor Capello of the Lisbon Observatory has, however, made progress with his reductions, but already published valuable information regarding the mean diurnal fluctuation of the two force elements at his observatory.

In his attempt to eliminate the disturbance of horizontal and vertical force by the method of Sir E. Sabine, Señor Capello experienced considerable difficulty, more particularly with the curves of the vertical force magnetograph. The instrumental bifilar has very often been found by him to change the zero of equilibrium after some perturbation. As in the case of the hourly variation of the horizontal and vertical forces, so in the case of the diurnal variation, Señor Capello found it necessary to reject from the discussion the days of great magnetic disturbance, and also those days which, though free from great disturbance, indicated a considerable amount of disturbance, estimated according to a general scale. In the reduction of many thousands of photo-

Year	Mean	Mean	Mean	Mean	Mean	Mean	Mean	Mean

Plate III. the declination range of 13′, the horizontal force a preponderance in summer and minimum in winter, a tendency towards two maxima and two minima in winter, and two maxima and one minimum in summer.

69. *Diurnal Inequalities of Horizontal Force at Different Periods of the Year.* Ellis has compared the hourly values of the horizontal force as well as that of the declination at Greenwich with the period of sun-spot frequency. He compares the years from 1847 to 1877, and he has deduced the following conclusions:

[1] See also Ellis, *Observations at Hong-Kong*, Introduction, p. 6, first to point out the relation between the state of the sun's surface and variation in the horizontal force.

e diurnal range of the magnetic element- of declination
rizontal force are subject to a periodical variation, the
of which is equal to that of the known eleven year sun
od.

e epochs of minimum and maximum of magnetic and sun
t are nearly coincident the magnetic epochs on the whole
g somewhat later than the corresponding sun spot epochs
ation- of duration in different periods appear to be similar
phenomena

e occasional more sudden outbreaks of magnetic and sun-
ces, extending sometimes over a period of several months,
o occur nearly simultaneously and progress collaterally

Disturbance Diurnal Inequalities and Force Components. We
ive the following conclusions on the results obtained by
on the observations at Toronto St Helena and
ment there are two categories namely, those disturbance
ency to increase and those which tend to diminish th
magnetism

Toronto the disturbance increasing both elements of force
ore or less progressively with maxima occurring for both
or 5 hours local time Again the disturbance decreasing
ment represented by
ma
e for both at about 11 or 12 hours local time

Kew the disturbance increase both elements represent
ly progression with maxima occurring for both about 5
l time On the other hand, the disturbance decrease in
rizontal force represents more of a double progression in
turning the vertical force seems of a simple progression the
to be the latter falling between the two maxima for the
and occurring at 11 hours local time

ere is not the same close correspondence between the
of the disturbances which tend to increase both elements
ect the presence of those which tend to decrease both
at St Helena there is for the other stations a
ble difference between the numbers for St Helena and those of
or Kew is there a difference between the numbers for Toronto and
Kew

he fact that the disturbance diurnal variations of the two
ments at Kew are very like each other while neither of
very like the corresponding declination variation is
confirmation from a visual inspection of the Kew curves

ure, it is probable that similarity of appearance in the
uctuations of the three elements denotes a simplicity in the
force, Stewart has discussed all such peaks and hollows
extending over the first two years of their production, and
the result which is embodied in the following table

TABLE XVIII *Hourly Ratios and Frequency of the Ke
and Hollows, the Vertical Force Disturbance being t
Unity*[1]

Hour	Declination	Hor Force	Number of Observations	Ho	Declination	Hor Force	Nu Obse
0 1	2·11	2·06	7	12 13	1·16	2·63	
1 2	1·94	2·16	7	13 14	2·00	2·04	
2 3	1·86	1·99	11	14 15	2·10	2·14	
3 4	1·81	2·05	7	15 16	2·05	2·11	
4 5	1·55	1·75	4	16 17	3·18	2·16	
5 6	1·57	1·51	1	17 18	3·80	2·11	
6 7			0	18 19	2·91	2·18	
7 8	1·83	1·91	2	19 20	·97	2·25	
8 9	1·69	2·70	4	20 21	1·11	2·21	
				21 22			
10 11	1·33			22 23			
11 12	1·10			23 24			

71 It will be seen from this table that the ratio between
maxima peaks and hollows of the two components of the force
nearly constant, the horizontal force disturbance being about
that of the vertical force, so far as can be seen on the curve i
It will also be seen that there is a very marked diurnal
the ratio which the declination peak or hollow bears to the
vertical force, this ratio being greatest about 7 A.M. Also
here we have almost peaks and hollows, while in the even
early morning hours there is so great an absence of these phe
that the ratios are doubtful

75 A preliminary comparison between the peaks and
at Lisbon and at Kew has been made by Capello and
(*Proc. Roy. Soc.*, January 28, 1864) with the following conc
(1) The Kew peaks and hollows are simultaneously proc
Lisbon in all the elements, but to a smaller extent than at
(2) The direction is the same at both stations for the dec
and horizontal force peaks and hollows, but it is reversed in
of the vertical force, so that a sudden small increase of verti
at Kew corresponds to a diminution of the same at Lisbon
It would be manifestly impossible to discuss with any ac
the nature and origin of these peculiar changes until mor
ive observations of them have been made. As the p
hollow force is probably of a simple nature, a further know
its character may be of much importance to the theory of te
magnetism.

It is interesting to remark that we have in peak and hol
the close relation between the variations of the two forces
that we find in the larger disturbances

It is believed too that during violent disturbances a
change of type is produced in the peak and hollow force, a
especially this remarkable in the great disturbance in Aug
September 1859, where the declination would seem to mar
opposite direction from the two components of the force.
seen that the same peculiarity characterized on this occa
larger and more apparent magnetic changes. We shall af
refer to a circumstance which may perhaps throw light u
peculiarity (§ 93), meanwhile we conclude by again remark
during comparative magnetic calms the peak and hollow for
signs of remaining constant in type, and that it is the
great importance that the directors of observatories possess
recording magnetographs should take united action to obse
force

76 *Other Inequalities of the Disturbance-Diurnal Variati
Force Components.* Sabine has shown that disturbances of
components present a distribution over the various month
very similar on the whole to that which is exhibited
turbances of declination. He has likewise shown that distu
of the force components present a distribution over vario
similar to that exhibited by disturbances of declination
we may probably conclude that disturbances of the force com
are smallest at those portions of the earth's surface where
ances of the declination are smallest, and largest at those
where such disturbances are largest.

77 *Annual and Semiannual Variation of Horizontal F
Rep.* Broun (*Trans. Roy. Soc. Edin.* for 1861) has discus
results obtained by Sabine at his magnetical stations, and ha
that differential and absolute observations agree in telling
the horizontal force is smallest at the equinoxes and gre
the solstices Whipple has recently obtained the same res
the Kew observations

We have deduced the following table (XIX.) from the
absolute determinations that have been made at sundry pla
at the annual and semiannual variations of declination, ho
force, and dip are exhibited, "increase" denoting a push
west, and "decrease" a push to the east. The method of o
these has already been indicated in §§ 66, 67.

[1] We ought to mention that, with the exception of the one occasio
alluded to, a peak of one element always corresponds to a peak of an
ment, and a hollow of one element to a hollow of another

	Effect on Declination		Effect on Horizontal Force.		Effect on Dip

discussing the results of the table we shall assume that acts, and in all probability acts indirectly, upon the system of the earth. This point will afterwards be examined. Meanwhile, assuming this indirect action of the assuming, to fix our thought, that it is in close alliance convection system of the earth's atmosphere, we can readily that such solar action would act most strongly on the magnetic poles at the solstices, and that in the June solstice or poles in the northern hemisphere and in the December those in the southern hemisphere would be most affected. trong action on this kind upon either pole may be assumed to decrease the general magnetism of the earth, or that portion of it which is most readily affected by external that is to say, the induction system. Again, if the solar influence is connected with the convection current of he can readily imagine that the influence in the northern ere where there is much land should exceed that in the hemisphere where there is much water.

these views be reasonable, we might expect two things to the earth's induction system should be strongest at the than at the equinoxes, and (2) it should be more especially the June solstice, when the forces in the northern hemis-

We must bear in mind, however, that a vast increase at a time applied to its particles most susceptible of may not be instantaneously propagated throughout but that time may enter as an element of the question, case, inasmuch as the action of the sun at the June solstice northern hemisphere, a station near the south pole may not take of the magnetic effects of this action.

hypothesis of this nature would appear to be consistent results of Table XIX.

first place, if the earth should become stronger as a magnet in both of its magnetic systems this would show itself by ase of horizontal force at least in all such stations as those absolute observations are made. An influence which the horizontal force at these various stations is therefore regarded, and was regarded by Broun as one meaning gth of one or both of the magnetic systems of the earth. of one or of both will presently appear. We may therefore from our observations that one or both of the earth's mag stems are strongest at the solstices.

next place we may imagine that the changes of declination which the table exhibits as occurring at the solstices are changes which would be wrought in these elements by an of power in the earth. For we see very well that an of horizontal force at the various stations may be regarded ing an increase of the earth's magnetic power. We cannot, see with equal facility what changes would be produced in nation and dip by an increase in power of one or both of netic systems, but we may well imagine that such change elements as are found to accompany an increase of horizon are those that denote an increase of the earth's power.

have thus ascertained the probable nature of those changes of e elements which denote an increase of power. Now it will ed from the table that the effect at the June as compared at at the December solstice is of the opposite nature to the the equinoxes as compared with the solstices, that is to earth is more powerfully affected in June than in December, well-established exception to this being Hobart Town in the h. But, assuming that time is an element in the develop this preponderating influence acting in the north, it is easy hy Hobart Town should not exhibit its full effect.

pains to determine from the observations themselves which magnetic systems it is that exhibits the observations would of course point to the induction system, but it is e to determine this from the observations themselves.

51, when discussing the disturbance diurnal variation of ion, it was found that Toronto and Kew may be regarded as side of the Siberian pole, while Peking, Nertchinsk, and are on the other. Now, if it be this pole that is influenced oscillations under discussion, we might expect that the influ declination at Toronto and Kew should be the opposite of Trevandrum and Bombay. We find by the table that this ase, and we are thus inclined to attribute these changes to erian instead of the American pole. It would thus appear that the observations of Table XIX bear out the provisional hypothesis which we have ventured to introduce. It is quite able that the above remarks may not stand the test of more inquiry, but they are here introduced rather as denoting a of looking at the subject which ought we think to be pursued embodying conclusions of a final nature.

80. *Effect of the State of the Sun's Surface upon the Magnetism of the Earth.*—We have now to consider whether state of the sun's surface permanently influences the magnetism the earth. It will at once be seen that any such action will ently manifest itself as an oscillation in the secular change. We however, carefully guard ourselves against prematurely concluding that it implies a variation in the amount of true secular change. There may be two distinct things: true secular change due cause, and action depending on sun-spots due to another. from the nature of the case, as necessarily mixed up together the yearly changes which we examine, it does not, however, follow there is any real identity between them. We shall now consider example of the method to be pursued in the attempt to detect influence of this nature. Let us turn to Table III., and take the nation yearly values at Toronto from 1856 to 1871. Subtracting value for 1856 from that for 1871, we find that the westerly declination had increased in fifteen years 51′·6, that is to say, at the rate of 3′·44 per annum. Again, the average declination for sixteen years 1856·71 is 2° 20′·8, corresponding to the end of the commencement of the year 1861. Taking the average value for this epoch, and also the average yearly increase above given, we proceed to construct the following table XX., in which calculated and observed values at Toronto are compared together.

1856	1 56·50	1 55·00	+1 30
1857	2 0·50	1 55·11	+2 06
1858	2 4·50	2 1·58	+2 6
1859	2 7·40	2 5·19	+2 05
1860	2 10·60	2 8·76	+1 51
1861	2 11·40	2 12·20	−0 20
1862	2 15·70	2 15·61	+0 06
1863	2 19·10	2 19·08	+0 02
1864	2 21·90	2 22·52	−0 62
1865	2 24·80	2 23·96	+0 84
1866	2 25·60	2 29·40	−1 80
1867	2 29·80	2 32·84	−3 04
1868	2 35·50	2 36·98	−1 48
1869	2 37·10	2 39·77	−2 67
1870	2 41·90	2 43·16	−1 26
1871	2 47·90	2 46·69	+1 21

may be gathered from this table that years which correspond to minimum sun-spots have on the whole a negative or lower positive sign than those which correspond to maximum sun-spots, and hence we may conclude that at Toronto tendency of many sun-spots is to increase the westerly declination.

81. Performing a similar operation for all those cases in which we have a sufficiently extensive series of observations to work upon, we obtain the following table:

TABLE XXI.—*Effect of Numerous Sun-Spots on the Magnetic Elements.*

Station	Declination	Horizontal Force	
Kew	Increase	Inappreciable	Inc
Toronto	Increase.	Increase	Inc
Hobart Town	Increase (?).	Uncertain.	Inc
Cape of Good Hope			
Trevandrum			

82. We have good grounds for supposing that the sun is powerful when there are numerous spots on its surface, and that the above table represents a state of things which we may expect to be caused in one way or another by increased solar power. The most natural hypothesis is to imagine that an increase acts in producing an increase of disturbances, and that from stations at which the disturbances tend on the whole to affect the elements in a definite direction there will be left behind a permanent effect in this direction. A comparison of Table XXI. with XII. will, however, show that this explanation is not valid. For instance at Toronto and Kew disturbances tend rather to

increase the westerly declination, while the effect of numerous spots is to increase it. Again, at the Cape the tendency of disturbances is to increase the westerly declination, while that of the sun-spots is to decrease it. At Trevandrum it would appear that the effect of disturbances will be to increase the westerly declination, while that of sun-spots is to decrease it. It is believed that at Kew and Toronto the supposed disturbance will act on the diurnal inequality in character with the sun-spot effect. On the whole, therefore, there is no definite relation between the two.

If we take Hobart Town, the Cape, and Trevandrum in the order, we find from Table XIV. that these stations seem to indicate that the magnetic state of the earth's most powerful hemisphere is one of maximum for sun-spots. Kew and Toronto, however, in declination and dip are not concerned appear to go the other way. If, however, we suppose that during the period of maximum sun-spots the American pole is well as the earth is affected, and that in such a position of long continuance as that the former is more influenced than the latter, we shall be able to bring out results with the hypothesis of increased solar action. It must be borne in mind that time must be an important element in the consideration of the effect of the American pole, and that, although its influence may not be apparent at Toronto and Kew, which are relatively near the pole, it would not be apparent at the other stations of Table XXI. We shall recur to this subject when discussing the secular changes.

Solar Phenomena connected with the Sun and with Terrestrial Magnetism.

Loomis's "Uniformity and Connexion between Solar Changes and Magnetic Disturbances." Loomis's "Increase Journal of ... [illegible]

He has tabulated the extent of sun-spots for the six days preceding and following each of the great magnetic disturbances at Greenwich, and has compared these values with that for the very day of the disturbance. In the manner he has treated all the days of the magnetic disturbance at Greenwich for a period of twenty years, with the exception of those cases in which very few or no sun-spots were made. The cases of disturbance thus treated amount to one hundred and thirty-five, and the following result has been obtained.

TABLE XXII. *Effect of Spotted Solar Surface.*

Day before Storm					Storm	Days after Storm				
6	5	4	3	2	1	1	2	3	4	5
47·9	50·1	51·4	[illegible]	48·4	9	49·0	45·1	40·3	45·6	45·2

From this result Loomis draws the following conclusions: "1. Disturbances of the earth's magnetism are accompanied by similar disturbances of the sun's surface on the very day of the magnetic storm. (2) The great disturbance of the sun's surface which accompanies terrestrial magnetic storms is generally heralded by smaller disturbances three or four days previous, succeeded by a comparative calm which immediately precedes the magnetic storm."

There is one instance on record of a sudden solar change which was practically simultaneous with a magnetic disturbance. On September 1, 1859, a little before noon, R. C. Carrington was viewing by means of a telescope a large sun-spot when, to use his own words:

> "the area of the [illegible] of which had previously been somewhat diminished, became covered with two patches of intensely bright light which broke out before I could fetch the time by the chronometer, and, scarcely crediting my own eyesight, I supposed that some optical effect had been produced by the brightness of the sun-spot. Running to the door of the equatorial room, I directed Hodgson, who happened to be sitting there, to watch the sun-spot carefully, and to call me if any change should occur, while I hastened to the position micrometer to obtain more exact measures of the two unexpected objects. On my return with the micrometer, Hodgson, who had seen the whole appearance, confirmed my impression that the two bodies had both moved rapidly forwards in company before they disappeared. Not more than five minutes could have elapsed between the first observation and my return to the room, and I was surprised to find that the sun-spot had entirely disappeared. In this short interval of time, which was taken for the time of disappearance, the whole area of the sun-spot, which had been covered with a multitude of minute spots, had travelled forwards in the direction of its own proper motion, and had become a single mass of light, of an oval figure, and of a uniform brightness throughout. Its boundary was well defined, and free from penumbra. Its area was about 10 millionths of the sun's visible hemisphere, or nearly equal to the area of the great sun-spot of November 9, 1847. Its light was estimated by Hodgson and myself to be fully equal to that of the photosphere in contact with it, and therefore much more than sufficient to fill up the deficiency of light due to the dark spots. Its motion was also determined by measures taken with the micrometer, and proved to be at the rate of 35·4 miles per second, or 1° 16′ 30″ per day. The two bodies preserved their distance unaltered during the whole time of observation. Their observed motion was in parallels to the solar equator, and in direct advance of the motion of the spots. Their positions were as follows:
>
> | | Sun's Centre | Distance | Position |
> |---|---|---|---|
> | | h. m. s. | | |
> | First body | 11 18 19 | 23·8 | 44·5 |
> | Second body | 11 18 19 | 23·8 | 44·5 |
> | First body | 11 22 30 | 23·8 | 44·5 |
> | Second body | 11 22 30 | 23·8 | 44·5 |
>
> "Before I could complete the micrometrical measures, the first body had entirely disappeared, and the second was fast following it.

e nearly twenty-six days. This assumes that the meridian
hat power is fixed on the solar surface. It does not, however,
npossible to imagine that such a meridian may have a proper
of its own, and indeed the planetary hypotheses of the origin
spots would rather lead to this conclusion. But if this be
e we shall be unable to deduce from recurrent magnetic dis-
es the true value of the period of solar rotation.

Repetitions of Magnetic Changes.—J. E. Capello, of the Lisbon observatory

nights (Walker's *Magnetism*, p. 80). We would make t
gestions before dismissing the subject.

(1) It is imaginable that these changes are caused by
influence acting vertically on some susceptible region of th
then, inasmuch as they occur at the evening or early nigh
this region must be considerably to the west.

(2) The region must also have a proper motion of its
Capello's remarks. Is it possible that this proper motio
the whole from west to east, a motion which we know is
by meteorological weather, and in which it is imagined th
magnetical weather as defined by us likewise participates?

88. *Comparison of Declination Curves at Stations n*
other.—Messrs. Sidgreaves and Stewart (*Proc. Roy. Soc.*, Octob
have compared together certain curves of the Kew and Sto
declination magnetographs. These magnetographs are of
pattern and it was found that on ordinary occasions the de
traces at both stations were precisely alike. This was c
by placing the curves the one over the other, when they wo
to coincide even in their most minute features. In time
turbance, however, it was found that the motions exhibite
Stonyhurst curves were greater than those at Kew, and th
of Stonyhurst over Kew depended not so much on the
size of the disturbance as on its abruptness.

This feature of the comparison is exhibited in the f
table (XXV.), in which the excess of Stonyhurst over Kew
divisions is compared with the abruptness of the disturba
element being measured by the change occurring in that o

Excess (under 5)	Abrupt	Abrupt nes	Exc cep 2	Abrupt	
		12	1		
		26	1		
		9	1		
		5	1		
0	31	4	1		21
1	29	5	1		21
1	12				
4	5				

It is very desirable that further comparisons of this natur
be made.

89. *Auroral Displays.*—The auroræ are very frequent not co
near the magnetic poles, while in middle latitudes they a
variable accompaniments of all considerable magnetic dis
the equator they hardly ever occur.

There is a considerable variety in the forms of auro
displays, and it is possible that there may be more th
variety in the cause or causes which give rise to them.

Loomis (*Smithsonian Report* for 1866) describes th
varieties: (1) a horizontal light like the morning twilight
of day; (2) an arch of light which frequently extends
across the heavens from east to west, and cuts the magnetic

right angles, in the polar region have each to be have
at once, the lender luminous beam or column with
and often of a bright belt, of the corona, the centre of
invariably near the magnetic south but not always
coincident with it, and of wave- or flashes of light
auroræ exhibit the same annual variation of magnetic dis
and are most frequent about the equinoxes effect first
by Mairan. Kreutz in his *Meteorologie* gives the follow

92. While the results now given leave little doubt as to t
of a connexion of some sort subsisting between sun spots
one hand and mag-
netic disturbances
and auroræ on the
other, yet it is
doubtful to obtain
evidence as to the
closeness of the
connexion between
aurora and sun
spots similar to
that which was
exhibited in § 82,
and which showed
the close connexion
as to amount of time
between sun spots
and disturbances.
Loomis has with
this view treated
auroræ in precisely the same way in which he treated distur
and has obtained the following table:-

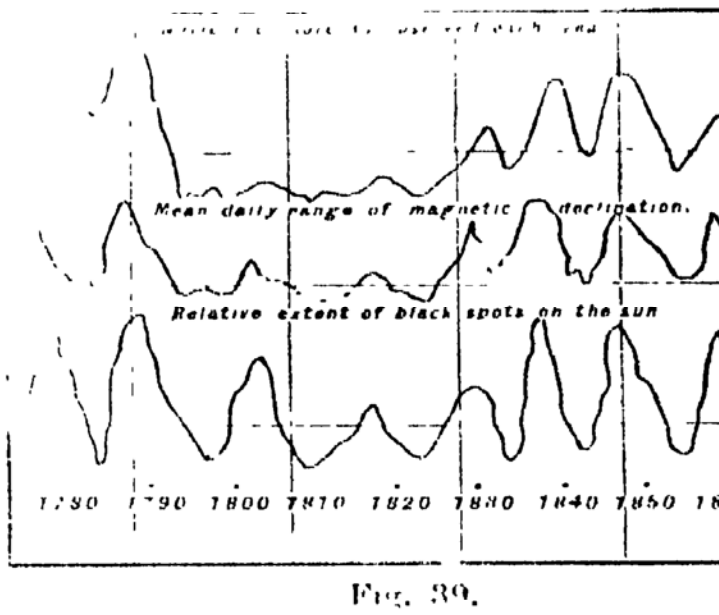

Fig. 39.

TABLE XXIX. *Extent of Spotted Solar Surface*

4	1
3	2
2	3
1	4

...of Days.

From which he concludes that "auroral observations in the
latitudes of America are generally accompanied by a ma
disturbance of the sun's surface on the very day of the auror

93. *Earth Currents.* These are electrical currents whic
place in the crust of the earth, and were first dete
W. H. Barlow (*Phil. Trans.*, 1849). At a later period the
and studied by C. V. Walker
Trans., 1862). They are now continuously recorded by photo
at the Royal Observatory, Greenwich. Earth currents are p
larly strong during magnetic disturbances. Sir George A
graphically compared together certain magnetic disturba
recorded by the Greenwich self-recording magnetographs a
simultaneous earth currents recorded by appropriate galvano
(*Phil. Trans.*, 1868), and find it almost impossible to avoid t
clusion that the magnetic disturbances are produced by ter
galvanic currents below the magnets. The like ness between
system of graphical representations is unquestionably very
ing. But, while there is no doubt an intimate connexion b
earth currents and magnetic disturbances, there is one
sideration which should make us pause before assigning the
as the complete and efficient cause of the latter. It
indicated by Lloyd:-

"When we examine the curves in which Mr Barlow has represented th
of the galvanometric deflections caused by the earth currents we observe
peculiarity of that course, continually interrupted by rapid reciprocatin
ments in which the needle oscillates from one side to the other of
alternately. These movements are similar to those of the magnetome
which we are familiar, but they are much more rapid and bear a large
tion to the regular changes. I have selected for calculation th
version made during the six hours commencing at 3 P.M. on May 29, 1
being a period of comparative disturbance. The sum of the change
division-scale needle during that period, on the Derby and Rugby
corresponded to 571 divisions of the instrument, the mean daily range
entire week being 114 divisions and the ratio 50. The sum
changes of the Greenwich declinometer during the same period was
minutes, the mean daily range being 14·1 minutes. In like manner th
the changes of the horizontal force was 0158 and the mean daily ran
The ratios according to the sum for the two magnetic elements, and it
remarkable that one tenth of the corresponding ratio in the case of the
magnetical change. We learn therefore that the rapid changes of t
currents are much greater in proportion to the regular daily changes
corresponding movements of the magnetometers."

We shall return to this subject in a subsequent part of this

94. *Incandescence as Terrestrial Magnetism caused by the M*
Kreil in 1841 was the first to point out that the moon has
influence on the position of the declination needle, and
afterwards the same fact was independently discovered b
Allan Broun. The more recent observations of Sabine
Broun, but especially those of the latter, have thrown mu
upon the nature of this action. As the lunar influence
generally large, it is necessary to free the observations fr
results of other inequalities, and this has been done by
observers above mentioned. The results given in Table
have been obtained by Sabine (see Walker's *Magnetism*).

95. Thus (1) the mean effect of the moon upon the
tion needle is to cause in each lunar day a double oscillati
Sabine has shown that the lunar influence upon the other m
elements is of a similar type. (2) The turning points f
hemispheres are in all cases not far removed from the luna

table + indicates that the north end of the magnet the east and is to the west of its mean position

18. (3) In the northern station we have a maximum deflexion about the hours 0 and 12 and a minimum easterly about the hours 6 and 18, while in the southern stations on is the reverse of this. (4) The oscillations would appear ost decided at those stations, such as Toronto and Hobart hat are far removed from the equator.

unual Variation of Lunar Effect. Broun has recently with much success the peculiarities of the lunar influence at um, and has obtained some very unexpected results. His lt was that the nature of the lunar influence upon the de n needle at Trevandrum depends upon the time of the year, the southern type of lunar action predominates at Trevan ring the winter and the northern type during the summer. If we take the mean of the whole year, then probably hern type will be found to predominate.

ean Lunar-Diurnal Variation during the Day and during Nt.—Broun has shown that the action of the moon on the on needle at Trevandrum is greater in every month of the ring the day than during the night. The following table) gives the day and night ranges for the various months ir ratios.

0·82	0·47	0·49	0·41	0·24	0·36	0·40	0·29	0·31	0·23	0·41	0·69
0·24	0·26	0·23	0·22	0·11	0·11	0·22	0·18	0·21	0·21	0·20	0·24
3·6	1·8	2·1	1·8	1·6	3·2	1·9	2·1	1·5	1·1	0·1	1·0

uld appear from Broun's observations that there is a e of type as well as a difference of range.

unar Diurnal Variation with Reference to the Moon's .—Both Sabine and Broun have shown that the variation er for perigee than for apogee. Broun has found that the tio of the apogee effect to the perigee effect is as 1 to 1·21. He remarks that "the ratio of the moon's mean distance earth in the half orbit about apogee is to that in the half out perigee nearly as 1·07 is to 1, as the cube of 1·07 is rly, we see that the mean ranges of the curves for the two s are in the approximate ratios of the inverse cubes of the distance from the earth, as in the theory of the tides.

unar Diurnal Variation with Reference to the State of s Surface.—Kreil in a memoir presented to the Imperial y of Science in 1852 considers that the observations at and Milan tend to show the existence of a solar period in variations. Sabine (*Phil. Trans.*, 1856) has discussed the observations and also (*Phil. Trans.*, 1857) the Hobart Town ions with the view of deciding this important point, and has the conclusion that there is no systematic difference in the ration corresponding to the decennial period of the solar variation, but merely such casual fluctuations as might onably expected, considering the shortness of the period ney represent.

ve made a preliminary discussion of Broun's Trevandrum ions with the view of throwing a little more light on this. For this purpose we have taken the ranges of the lunar variations recorded by him for each month of each year. e in the first place grouped these ranges together into representing quarterly results, and have then compared these quarterly results for years of small and for years of great sun spot frequency,—assuming the years 1854 56 and represent the former, and the years 1857 62 to repre latter. We have thus obtained the following result:

TABLE XXXII. *Relation between Lunar-Diurnal-Ran Declination at Trevandrum and Sun Spot Frequenc*

	Great Sun-Spot Frequency.	Small Freq
February, March, April	0·501	0
May, June, July	·464	
August, September, October	·501	
November, December, January	·641	

It would appear from this table that such ranges are gr year of maximum than at year of minimum sun spot fr Nevertheless the proof is not conclusive inasmuch as with such lunar ranges we may have remnants of solar dist the tendency of which might possibly be to increase the ranges. Now such disturbances are more frequent at maximum sun-spots, and it might therefore be contend this tendency would be to increase the apparent lunar such times above the range corresponding to year of m sun-spots. On the whole we are not disposed to think evidence already adduced is sufficient to decide this as a matter of fact either in the one direction or in the othe

100. *Variation in the Diurnal Range of Declination upon the Age of the Moon.* Chambers (*Annals of Trivandrum*, 1876) and Stewart (*Proc. Roy. Soc.*, 1877) have found that the range of declination is greatest about th of new and full moon, a result recently confirmed by C. C of Bombay. The following are the results recorded by derived from 19½ lunations at the Kew Observatory.

101. *Earth Currents caused by Lunar Influence.* Mr A J. S. Adams (*Nature*, March 3, 1881) has made use of a t wire the ends of which were connected with the earth, th Cardiff and the other at London. He observed the current wire every quarter of an hour from March 28 to April 2 He believes that such are earth currents, and that they lunar diurnal variation. There are during the lunar day a to this observer, four electrical maxima, two positive and tw tive, each maximum being bisected from the next by a point of no current. His results likewise exhibit a regular tion of la of the earth current variations behind th to the extent of nearly three but these require confirmation from further observations.

THE EFFECT OF SOLAR VARIABILITY ON THE METEOROL OF THE EARTH.

102. We may learn from the preceding paragraphs t sun exerts a more powerful influence upon the magne the earth at times of maximum than at times of minimu spots. It remains now to find whether a similar v obtains in the phenomena of terrestrial meteorology. I purpose we may divide the meteorological elements into divisions of pressure, rainfall, wind, and temperature, inqu what manner the are affected by solar inequalities.

103. *Pressure.* In 1871 Blanchet (*Memoirs of the Lit Society of Manchester*, 1871–72), from an analysis of eleve of the Radcliffe observations, Oxford, came to the conclu ars of maximum sun spots the maximum barometric occurred under north west wind and the minimum under west, while in years of minimum sun spots the maxim minimum pressure took place respectively under north an east winds. He came in error to the conclusion that, be difference in distribution of the convection currents of th the forces which give rise to the movements of the air appear to be greater in years of maximum than in minimum sun spots.

104. A study of the isobaric lines would appear to be method of obtaining information upon this important point well known that during summer the interior of large c have a peculiarly low and the surrounding ocean a pe high atmospheric pressure, while a different r reverse obtains during the winter months. May this be due to solar action, and we might therefore infer that w sun is peculiarly powerful the peculiar meteorological distribution found to be increased in prominence, while this will be di at times of comparatively weak solar influence.

The distribution of pressure has been traced with much ex by Indian meteorologists, including Messrs Archibald, H

Charles and Frederick Chambers, Eliot, and Hill and the
g conclusions is the result of their labours We may assume
Indo-Malayan region bri for the mean of the year a
re pressure probably below the general average of the

vations recorded during thirty years at the Cape of Goo
and came to the conclusion that the same cause which lea
excess of mean annual temperature at the Cape leads equ
operation of sun spot Dr W Koppen in 1873 discussed
lation to the connexion between sun spots and terrestrial temp
and found that in the tropics the maximum temperatur
follows a year before the minimum of sun-spots, while in t
beyond the tropics it occurs two years after the minimu
regularity and magnitude of the temperature wave are most
marked in the tropics.
112 The evidence now given appears at first sight to be
nistic to that derived from the other elements both of ma
and meteorology and to lead us to conclude that the sun
most when there are fewest spots on its surface. This co
will not, however be strengthened if we examine the subj
greater minuteness.

[5] *Brit Assoc Reports*, 1872.
[6] A Poëy *Sur les Rapports entre les Taches Solaires et les Ouragans de
de l'Atlantique Nord, et de l'Ocean Indien Sud.*

ifically we may regard the earth as an engine, of which is the furnace, the equatorial regions the boiler, and the gions the condenser. Now this engine may be supposed to the following manner. Hot air and vapour are carried e upper regions of the atmosphere from the equator to the means of the anti trade winds, while in return the cold is carried along the surface of the earth from the poles to ator, forming what is known as the trade winds. When sun's heat is most powerful both trades and anti trades- e most powerful likewise. But we live in the trades rather the anti trades in the surface currents, and not in the urrents of the earth's atmosphere. When, therefore, the ost powerful is it not possible that we might have a part strong and cold polar current blowing about us? The same ould happen in the case of a furnace fire: the stronger the more powerful the hot draught up the chimney, the more also the cold draught from without along the floor of the It might thus follow that a man standing in the furnace- ar the door might be chilled rather than heated when the itself was roaring loudest. In fact temperature is a phe no- due to many causes. Thus a low temperature may be due deficiency in solar power, (2) to a clouded sky, (3) to cold to cold winds, (5) to cold water and ice, (6) to cold pro evaporation, (7) to cold produced by radiation into space ord has recently shown that at certain Indian stations ean temperature occurs when there is an unusually large and a great amount of clouds, a result in accordance with lusions previously enunciated by Professor Piazzi Smyth. of maximum and minimum temperature must not there too closely associated with a maximum and minimum of wer.

Considerations of have induced Stewart to (*Nature*, June 16, 1881) that the true connexion between s and terrestrial temperature is more likely to be discovered dy of short period inequalities of sun spots than by that of en-year period in which there is time enough to change the etric state of the atmosphere and the whole convection of the earth. He has accordingly discussed at some length innent sun spot inequalities of short period (about twenty- rs), and endeavoured to see in what way they affect terres- mperature. From this it appears that a rapid increase of s is followed in a day or two by an increase of the diurnal ture range at Toronto. Now an increase of diurnal tempera- ge most probably denotes an increase of solar energy, and has led to associate an increase of solar heat with a large ment of spots. This, however, is a point which requires nvestigation.

General Conclusion.—On whole we may conclude that eorological motions and pre of the rth are probably tive at times of maximum sun-spots, and that they agr gnetical phenomena in representi g the ra- most power uch occasions, although the evidence derived from meteor- not so conclusive as that derived from magnetism.

ETICAL VIEWS REGARDING THE CONNEXION BETWEEN THE TE OF THE SUN AND TERRESTRIAL MAGNETISM

Principles of Discussion. In the following discussion we ly to advance a working hypothesis, with the view of sug- further inquiries into the subject of terrestrial magnetism. s therefore desirable that we should limit ourselves to such or possible causes as are known to exist and to operate on h. These various agents or causes will be described, and endeavour to show that converging lines of evidence point al cases to certain of these as being most likely to produc rticular type of effect which is exhibited in terrestrial sm. This course will in our view most readily suggest inquiries with the view of confirming or disproving the points of this working hypothesis. Believing that the tion of any unknown cause can only be justified when auses have been found insufficient to account for the pheno- question, we have not advocated any direct magnetic action un upon the earth. We have refrained from this for two —first, because from what we now know of the sun it to us unlikely that it should exercise an influence of this pon the earth, since a body at a high temperature possess- y strong magnetic properties is unknown to us; and, , we shall see further on that such an influence will not the best-understood magnetic changes, nor is there in our any magnetic phenomenon for the explanation of which it absolutely necessary to resort to this hypothesis. In fine, presuming to deny the possibility of unknown influences nature, it does not appear to us that the time has yet arrived e are called upon to resort to such as necessary aids to the y of further truth.

Nature of Solar Variations.—It is quite certain that there ability in the visible appearance of the sun's disk, which sometimes a comparatively large amount of spotted area while on other occasions it is entirely free from spots. No been remarked by Thomson that were the sun an incandesce its surface would become cool in a few minutes. The act property which our luminary possesses of pouring out conti a vast amount of radiant energy must unquestionably depe machinery of great power by means of which fresh hot are rapidly brought from the interior to the surface, whi particles which have given out their light and heat are hurried downwards to be recruited from the great store heat in the sun's centre. In fine, a gigantic system of co currents of this nature forms the essential condition witho the sun would not be able to continue shining as it does.

The mottled appearance of the sun's disk as seen through scope denotes no doubt the existence of a vast system of as and descending currents, the hot matter rising from be neat denoted by the brighter portions and the cold matter des from above by the darker portions of the structure. On occasions and in certain regions of the sun the scale of these ments is greatly increased, and we have a huge uprush o and a corresponding down-rush of black matter. In fine, t known sun spot with its bright faculous appendages. W sun-spots are very frequent we should therefore expect the co system of the sun to be particularly powerful, and the great and size of the red flames on the higher portions of the co system observed around the sun's limb on such occasions us in this supposition. And if the convection system of be particularly powerful when there are most spots on its it would seem to follow that the radiation from our luminary on such occasions be particularly powerful also. The spec leads us to the same conclusion. It would appear from th vations of Lockyer and others that at times of maximum s certain definite regions of the sun when examined spectros pres appearances of a very high temperat

We are unable to confirm these conclusions by direct obse of the sun's heating power. Actinometrical determinatio not yet been made with su ent accuracy and pe this point experimentally. We have, he direct nature derived from terrestrial magnetism and met all tending to make us think that the sun is most powerfu times of maximum sun spots. We have seen that on such the solar influence upon the magnetism of the earth is pe powerful in more than one way, and that its influence on logy is then peculiarly powerful also, although we are not s of this latter fact as of the former.

We may therefore take it to be most probable that the most powerful at times of maximum sun-spots, and proce this basis to propound the two following questions: in place, what is the the solar influence upon te magnetism? and, secondly, why is this influence so much mo perceived than certain forms of solar influe pon meteo

117. *Diurnal Magnetic Variations. Hypotheses regarding* The various speculations on the cause of these phenomen ranged over the whole field of likely explanations. (1) It supposed that the sun acts directly as a magnet upon the ma of the earth. (2) It has been imagined that convection established by the sun's heating influence in the upper re the atmosphere are to be regarded as conductors moving acr of magnetic force, and are thus the vehicle of electric which act upon the magnet. (3) Faraday, reasoning f discovery that oxy paramagnetic ld become weak power when heated, and stronger wh cold, supposed sun by heating certain portions of the atmosphere rende less magnetic while others, not subjected to any heating i are rendered more magnetic. The action is equivalent t placement by means of the sun of the magnetic matter of th and involves a displacement of the lines of force. Here solar action is associated with the great mass of the atm (4) It has been supposed by Christie and by De la Rive heat of the sun produces in the atmosphere and in the earth electric currents which produce the daily magnetic varia ti is not easy to perceive how we could have thermo-electric in the upper regions of the atmosphere but there is no objection to the generation of such currents in the crust of th Thus the first hypothesis has no reference to the atmo phe ever, the second deals with the upper atmosphere in con tact with the great body of the atmosphere, while the fourt have ventured to modify it, has reference to the crust of th

118. *Discussion of these Hypotheses.*—Dr Lloyd and Chambers[1] have both shown that direct solar magnetic ac not account for the peculiarities of the diurnal magnetic va Again (§ 48) we have strong evidence that changes in the the daily magnetic variation lag behind corresponding solar in point of time. Now this kind of behaviour is inconsist direct magnetic action, and points rather to an indirect effect caused by the radiant energy of the sun.

[1] *Proc. Royal Irish Academy*, February 22, 1858, *Phil. Trans.*, 18

Let us therefore dismiss the hypothesis of direct action and that of Faraday. We know both from observations of the ion and horizontal force (*Proc. Roy. Soc.*, March 22, 1877, *Phil. Trans.*, 1880, p. 341) that the action of the sun in pro diurnal variations of the declination is one and a half times erful at epochs of maximum as it is at epochs of minimum t frequency. It is hardly credible that there should be great differe in heating effect he great bulk of the atmosphere. Moreover there seems to have never d such a difference nor is there any marked corresponding ity of diurnal temperature range. Meteorological evidence garding the diurnal var due to the upply the sun of the great of oxygen which constitutes gnetic portion of the earth phere. Again, as there is ondensation of hot ocean va southern hemisphere during ne and in the southern hemisphere during the December there ought according to this theory to be a well marked variation of the magnetic meet the earth, the northern hemi be one at the one time differently affected from the southern ne no trace of such phenomenon, the annual and semi variation which we have already described (§§ 64–67) being confined to land and none of them very large.

Precisely the same objections apply with even greater force earth by other ... It seems impossible to allow that any effect on the earth caused by the sun can be one and time a great at epoch of maximum and at epochs minimum spot frequency.

We are thus driven by the method of exhaustion to look ... on of the earth's atmosphere probable ... solar influence in producing diurnal magnetic chang...

It need hardly be said that the only conceivable magnetic cause of operations in such regions must be an electric current ... know from our study of the matter that there are such ... in these regions. ... continuous near the pole and occasional ... latitude. A good deal has been said about the difficulty ...ining a daily set of current to be generated in regions of ...perfect conductivity; but we shall see by and by (§ 134) ...re is good ground for imagining that their conductivity may ...e greater than has hitherto been supposed.

Analogies between Meteorological and Magnetical Systems of the Earth. We have in the first place a zone of maximum ter... temperature, the middle line of which is nearly coincident ... with the geographical but likewise with the magnetical

Again, there are probably in the northern hemisphere ...es of greatest cold, which possibly do not greatly differ in ... from those spots which we have called magnetic.

About the southern hemisphere we have no information ... Furthermore, we believe that the hot air is carried from the zone ...est heat to the place or places of greatest cold by means, no ... of the return trade which blow in the upper atmosphere.

The hot air diverges at this zone, one part blowing northe... in the northern and another southwards in the southern ...here. Now this zone, from which the anti trades divide, ...annual motion of its own, being found farthest north at the ...stice and farthest south at that of December. Probably too ...thern system is strongest in June and the southern system ...ember. If we now turn to the solar diurnal variation of ... declination, we find here also a northern and a southern (§ 11), the type of the one being antagonistic to that of the ... We find also that the northern system is strongest in June ... southern system in December.

... it seems probable from what we have now said that the ... , strictly speaking, have reference not to the geographical ... and poles but to the zone of maximum and the poles of ...e temperature. Now, turning once more to the diurnal ...on of the declination needle, it seems probable that the ...ance last we must be interpreted as having a reference ...the geographical but to the magnetical pole (§ 15).

... analogies must be taken for what they are worth. Our ...n into discussing them has reference to the previous discussion, ...hich we expect that the magnetic influence of the sun is ...ly due to currents in the upper region of the atmosphere—...se of which we were content to leave in abeyance. Now ...nalogies we are led to suggest that this cause whatever ...y perhaps be found to be related to the convection system ...earth on the one hand and to the magnetic system on the ...

Analogies between Meteorological and Magnetical Weather. — ...marks are borne out by the further analogy which appears ...st between what we have called meteorological and mag... weather. Let us take the solar-diurnal variation of declina... Not only is the variation similar in form to the diurnal ...n of atmospheric temperature (§ ...), but the ranges of the ...ve a similar annual variation. And, as the element of ...ological weather affects the orderly march of the temperature ...must be element... etical weather affects the orderly ...f the declination range.

Furthermore, just as temperature-range weather progress... west to east (§ 52), so declination range weather would seem ...gress in the same direction as the other (§ 52) although at a ...rate. It will doubtless require a more extended investiga... make us quite sure of this latter point; nevertheless we ... perceive the validity of the objection that is sometimes made ... hypothesis of progress in magnetic weather on the groun... magnetic influences are known to affect all portions of th... simultaneously. It will, we think, be perceived that in th... statement no supposition whatever is made with respect to t... of propagation of a magnetic influence through the earth, th... be instantaneous or it may not. It is supposed that we ha... a travelling cause of excitement, say a travelling cause of e... in the upper regions of the atmosphere which progresses from ... east and always ... its greatest marked effect above those ... where it passes just as the sun itself in passing from east ... produces a magnetic effect the various phases of which trav... east to west with the sun which causes them. We think too t... hypothesis of travelling causes of magnetic change is streng... by the fact observed by Capello and described in § 97.

124. If, however, the objection made to this hypothesis ... the fact disclosed by Broun (§ 80) that changes of horizont... appear to take place simultaneously at distant parts of the ...urface, then we think that analogy should lead us not to d... possibility of a travelling magnetic excitement, but rather to ... the possibility of there being some meteorological influence ... like the magnetical one above mentioned, may be found ... place simultaneously at different parts of the earth's surface. Broun (*Proc. Roy. Soc.*, May 11, 1876) has given us prel... evidence for supposing that there are simultaneous barometri... tions. For instance, there was a barometric maximum at ... Town, Peking, the Cape, St Helena, Makerstoun, Su... Madras, Simla, Ekaterinburg, and Bogoslovsk about the ... March or first day of April 1845. There appears to have ... simultaneous increase of the horizontal force of the earth at ...stations much about the same time, and there also appears ... been a short period maximum of spots on the solar surface. ... has likewise registered simultaneous barometric variations a... pore, Madras, and Simla, for the first three months of 1845 ... these it would seem that simultaneous barometric maxi... possibly coincident with rapidly increasing sun-spot areas.

Again is it not absolutely certain that if there is a sudden ... of solar power this must mean an increase of heat comm... to the earth, although it may be difficult or even impos... tain experimental evidence of such a fact? All these a... ts which require further investigation.

125. *Further Remarks on the Solar-Diurnal Variation of Declination.* In § 24 we have asked how far the action of t... diurnal force upon a freely suspended magnet is due to ... acting directly upon the magnet and how far to a change p... in the magnetism of the earth. Some light appears to be ... on this point by the behaviour of the needle at places ... magnetic pole where the dipping needle is nearly vertic... opposite sides of this locality the declination needle points ... side directions. Now suppose that we have a set of such ... placed all round this region. It seems a legitimate genera... from the observations described by Sabine (§ 45) to conclu... if we place ourselves above the centre of any of these ne... S A M., and look towards its marked pole, we shall find it ... case deflected towards the right, while if we look towards t... pole at 2 P.M. we shall find it deflected to the left. No... imagine that at 8 A.M. there are above these magnets (in th... atmospheric regions) electrical currents of which the ho... components form a set of positive currents flowing from the... all sides, then by the known laws of such currents the mark... of all these needles will be deflected towards the right. A... P.M. the resolved portions of such currents should be ... towards the pole, then the marked poles of all these needles ... deflected towards the left. It thus appears that this ... magnetic behaviour might easily be explained by a hypo... distribution of currents. And in fact in such regions we h... dubitable evidence of the existence of currents in the upper ... of the atmosphere. On the other hand this behaviour co... easily be explained by the hypothesis of some definite ter... magnetic system set up by the solar influence in the earth ... such a case we should imagine that similar poles of all the ... ought to be deflected towards the pole of this temporary ... which is not the case.

126. Another point for consideration is the possible con... of the solar-diurnal variation. For we may imagine (1) t... sun acts in such a manner as to produce a diurnal variation ... may also act like the moon (§ 91) and produce a semidiurna... tion; (3) these possible actions may be accompanied by ... currents in the upper regions of the atmosphere and in the ... the earth; (4) it is possible that the sun's rays may affe... variations or some of them in the way in which Broun fou... the lunar variation at Trevandrum was affected by the s...

d by him that the lunar action was considerably increased
e sun was above the horizon of the place.

We have pointed out (§ 119) that, while there is a marked
in many respects between the diurnal variation of declina
l that of atmospheric temperature, we have yet no long
netuation of the diurnal range of temperature at all com
in magnitude to the magnetic fluctuations. It does not,
, seem difficult to account for this difference if we imagine
magnetic fluctuations take their origin in the upper atmos
regions, while the temperature fluctuations are due to the
gions of the earth's atmosphere. For, as the sun increases
t from times of minimum to times of maximum more pot
ey, we may imagine that a continuously increasing amount
ous vapour will be taken into the earth's atmosphere.
the experiments of Tyndall and others induce us to think
air would under such circumstances become more and more
or certain rays of the sun, and thus continuously elect
portion of the sun's heat would be able to penetrate into
er atmospheric regions. This latter influence would there
rate to cloak perhaps to a considerable extent, the effect of
's increasing power; and this may very well be the reason
temperature range at the earth's surface does not exhibit
e eleven yearly inequality as the declination range.

There seems, however, reason to believe that if we go from
short period inequalities there is a much greater similarity
range of the magnetical and the meteorological changes.
The explanation seems to be that in the short-period changes
has not time to alter sensibly the constitution of the atmo
and hence the proportional increase of effect experienced in
per atmospheric regions is more nearly the same as that
ced near the surface of the earth.

Magnetic Disturbance.—There is strong evidence that the
portant disturbances break out very nearly simultaneously
ly different parts of the earth, and that they even affect both
heres at the same time. Very little, however, is known
e *modus operandi* of the forces concerned in producing such
nances. For instance, it is not known whether a disturbance
ently affects the magnetic state of the earth, *e.g.*, whether
he magnetic elements before a disturbance become sensibly
t in value from what they were after the disturbance has ceased.
On the other hand we know (1) that disturbances break
the very day when there are rapid changes taking place
sun's surface (§ 83), (2) that [illegible] ly begin by
tarily increasing the horizontal force, but that the
changes, so that during most disturbances the horizontal
diminished (§ 86); (3) that large disturbances take place
rticularly about the equinoxes, when, we have reason to
the horizontal force of the earth is at a minimum (§ 77).
not possibly conclude from these habits of action that at
f disturbance the earth is magnetically in a delicate state of
rium, perhaps having more magnetism than its surroundings
strictly warrant, and being therefore inclined to part with
nd that a sudden increase of solar activity tending, as such
probably do, at first to exalt the magnetism of the earth,
eless destroys its magnetic balance and gives it ultimately
ortunity of parting with some of its magnetism? This can
regarded as a speculation, inasmuch as we do not know
r or not a disturbance produces any permanent influence
e magnetism of the earth.

Auroras and Earth Currents.—There is no doubt that these
ena denote electric currents in the upper regions of the
here and in the most conducting crust of the earth. The
dispute is with respect to the origin of such currents.
re inclined to regard auroras as peculiar manifestations of
herical electricity in high latitudes, while others imagine that
splays are rather of the nature of induced currents generated
ll but abrupt changes taking place in the magnetism of the
The advocates of the first view do not deny that currents
place somehow in the upper atmospheric regions will have their
ons modified, to some extent at least, by the inducing influence
netic changes. Nor will the advocates of the induction hypo
e disposed to deny the possibility or even the certainty that
s due to atmospherical electricity and not dissimilar to some
aurora take place in some region of the atmosphere. But the
ty regard auroras rather as the cause than as the effect of mag
anges, whereas the advocates of induction regard such displays
as the effect than as the cause of changes somehow produced
nagnetism of the earth. And here it is desirable to remark
e advocates of the induction hypothesis take for granted the
ism of the earth and the changes thereof as phenomena for
they do not profess to account, whereas unless we go to some
ely unknown cause (and this is against our present pro
e) we must look to atmospherical electricity as likely to throw
on the origin of terrestrial magnetism. We cannot therefore
e with regarding atmospherical electricity as an agent which
ve played an important part in the development of the
magnetical condition of the earth, but we are yet of opinion
that, under the present state of things, the theory which be
atmospheric electricity must largely be supplemented by the
tion hypothesis if it is to explain the peculiarities in type
of the phenomena which observation brings before us.

131. Professor Tait in his essay on thunderstorms attribu
kind of aurora to atmospherical electricity. Such an auro
believes, the manifestation of almost continuous discharg
those given by a Holtz machine in a vacuum tube. The
condensation of vapour going on very slowly in very large
es. The electricity is due to previous contact of particle
and vapour. The result is that the air particles in the nay
time acquire a definite difference of potential from those of ve
so that, when the latter aggregate, a nimbus region well charge
sult, and this discha[illegible] to the oppositely elect[illegible]

132. Again, Professor Stokes, without attempting to ac
the origin of atmospherical electricity, has produced an hy
with the view of explaining the intimate connexion w
between auroral displays, earth currents, and magnetic cha
the one hand and outbursts of sun-spots on the othe
clears that two somewhat distant atmospheric regions A an
charged, let us say, with positive and negative electricity
tively. A induces in the ground below it a charge of negat
charge of positive electricity. At first things are held in thi
A cannot discharge either through the upper atmospheric
to B or through the lower regions to the ground beneath
B in a portion precisely similar. Presently, however, in
of the radiative power of the air produced. Such an
would probably imply not merely an increase in general a
but a particular increase in such a time rays as are absorbed
upper regions of the earth's atmosphere. The layer of air
between A and B will therefore speedily absorb such ra
perature will rise, and as is known to be the case for ga
electrical conductivity of the stratum will be in
charge will therefore ultimately take place in the upper
between A and B; this will relieve the charge of negat
positive in the ground immediately beneath A and B an
charges will therefore rush together through the ground, pr
an earth current. This earth current will be in the oppos
tion from the atmospheric current, and the two will com
represent, virtually at least, if not absolutely, a closed circu
will of course affect the earth's magnetism and produce a di

133. This hypothesis certainly affords a good explanatio
promptness with which disturbances follow increased solar
[illegible] to resort to some unkn
cult to think of any other possible explanation of the fact
an explanation appears too to receive corroboration from
(§ 97) [illegible] lunar influenc[illegible] rth's magnetism a
at Trevandrum is greater during [illegible] day than during the
greater possibly too at times of maximum than at time of m
sun-spots. We are therefore dispo[illegible] in
the way in which increased solar activity produces ge
turbance are the best that have been brought forward.

134. This does not, however, decide the disputed point
these elevated currents are due to atmospheric electricity
lar to induction. The argument against the possibility of
currents in these regions is derived from experiments with
tubes, such as those recorded by Messrs. De la Rue and Muller
would seem to indicate that enormous differences of potenti
be required to produce electrical currents in elevated region
the atmosphere is very rare.

Indeed, on account of these experiments, the measure
the old observers, who sometimes assigned a height of mo
100 miles to the aurora, have been called in question, and
been supposed against direct observation that these phenome
always occur in regions [illegible] elevated. It would ap
that such reasons were influential in determining Professo
to regard the aurora as produced by atmospherical electricit
as we know from ordinary lightning, presents us with
differences of potential [illegible] but it is to be remarked that he
fully guarded himself against the possibility of laboratory
ments with vacuum tubes not being strictly analogous to th
takes place in the upper atmospheric regions. Now it would
that recent experiments by Hittorf throw some doubt u
strictness of this analogy. The high difference of potential
to force the current through vacuum tubes is, according
observer, due in great part if not entirely to the pass
from the terminal to the residual air of the tube, so that th
tial requisite to pass a current through a tube of double l
not sensibly greater than that required for a tube of single
The whole subject is one which demands further investi
meanwhile we are not disposed to accept the [illegible] auro
tion currents taking place in the upper atmospheric region

135. Let us now consider whether the form and type of t
currents observed during disturbances favour the presence
tion to any sensible extent. The remarks of Dr Lloyd
quoted (§ 93), which are confirmed by the [illegible] observ
seem to be decisive in this respect. These may be interp

owing manner In a magnetic disturbance we have fre- a general displacement of the various elements the hori ce, for instance, now on the curve which represents this considerable displacement a large number of comparatively t very abrupt changes are superimposed These latter es are invariably accompanied by quick strong alter from positive to negative of the earth currents, while the low motion, although it may be of large range, hardly to have any galvanic equivalent or no The would appear the induction hypothesis, according to which small but magnetic changes should give rise to strong earth currents ly positive and negative without reference to the position magnet above or below the horizon at the time

Another fact bearing upon the hypothesis mentioned From the it would appear that on ordinary occasions the ording the process of the declination needle at Kew and r traces as nearly as possible identical but on occasions of ge the range at Stonyhurst is greater than that at Kew by ut not apparently in dependence in any way on the magnitude of turbance at the time of disturbance The introduction of the of abruptness would appear to be in favour of the mix n of earth currents with the phenomena n

surface Airy has not been able to detect any resemblance between the diurnal progress of the magnet and that earth currents It seems, however possible that the peaks dotted lines 7 7 may form an important integral ne daily magnetic movement and there even appears to be dence that the annual progress of the earth currents bears resemblance to that of the peaks and hollows than it does progress of the monthly curve which is usually held to the diurnal variation But this is a question which can ided by more prolonged investigations

To conclude, there can be no doubt that at times of great ab disturbance we have currents in the upper atmosphere and in the crust of the earth which, so far as we can see, her be due to atmospherical electricity or to induction, or tance of both The proportion of the mixture can only be by further inquiry and by the multiplication of stations mospherical electricity and earth currents may be observed t to be mentioned that the experience of the Kew observers thus extends, is unfavourable to the hypothesis of a on between aurora and atmospheric electricity.

Lunar Solar and Lunar-Solar From the fact observed by 8 that the moon's magnetic influence varies nearly as inversely proportional to the cube of the moon's distance earth it is impossible to refrain from associating it either ectly or indirectly with something having the type of tidal action, what way this influence operates we cannot tell. Is it that the earth current observed by Adams (§ 101) are n current generated in the conducting crust of the earth magnetic change caused by the moon, inasmuch as these were found by him to be strongest in one direction about t hours 3 and 15 when the lunar diurnal magnetic effect me most rapidly in one direction (§ 95), while they were be strongest in an opposite direction about the 9 hours , when the lunar-diurnal magnetic effect is changing most in an opposite direction?

We might perhaps expect from the analogy of the tides that should possess a semidiurnal magnetic effect similar in type of the moon Now Sir George Airy in his analysis of the ments observed at Greenwich (*Phil Trans*, 1870) during Hampton magnetograph has detected in such currents a semi- inequality having maximum in one direction at solar hours , while it has maxima in the opposite direction at solar hours The reference to solar hours in this inequality is thus similar to that which the inequality observed by Adams lunar hour

If there be induced currents of this nature in the crust of h we might reasonably suppose that there will be correspond- ents in the upper regions of the earth's atmosphere, and in ce with the suggestion made by Professor Stokes (§ 132) t perhaps suppose that these currents will be strongest when r atmospheric regions are heated by the sun and thereby l better conductors It is not possible to suppose that the of daylight upon the lunar magnetic effect discovered by § 97 may be due to this cause, and may it not also induce cognize the possibility of a maximum lunar influence (§ 99) of maximum sun-spots when there is reason to believe that diation is most powerful?

Secular Variation —Sabine and Walker are agreed in g this variation as cosmical in its origin and they are ly of opinion that it is caused by some change in the con- f the sun. It seems difficult if not impossible to attribute ything else, since the terella of Halley cannot be now as having a physical existence. Again it is more than it is probable—that there are solar variations of much longer period than eleven years On the other hand the given in § 81, tending to show that an access of sun-spots pr change in the magnetic state of the earth consistent with t thesis that the magnetizing power of the sun has th augmented, requires to be confirmed by more observatio even then it is certain that this magnetic change produc considerable change in spotted area is extremely small. W therefore regard the very large secular magnetic change as non-cumulative magnetic influence of some long continu variation, nor does it seem possible to attribute the cl solar influence at all unless we regard this influence as pr results of a cumulative nature

It is possible however, to regard solar influence as prod cumulative effect in one of two ways, or by a combination For Time is necessarily an element in any influence acti the hard iron system of the earth -presuming the earth to such a system. There are in fact indications in the result that a system of this kind is perhaps connected with the A pole yet, even allowing the influence of time, it seems dif account for the peculiarities of the secular variation by a thesis of this nature But (2) any long continued variation power would no doubt act cumulatively in producing an in diminution of the large pear-fields round the poles of the ea the course of time this cumulative change in the extent position of these might perceptibly alter the distribution convection currents of the earth—and these, according to th herein indicated, might in their turn perceptibly alter the magnetic system

113. *Concluding Remarks.* If we agree to look for an exp of terrestrial magnetism and its change to strictly terrest causes, we may derive some assistance in our search from s siderations connected with symmetry as enable us, for exa once to perceive that when two perfectly similar things are together we cannot have electrical separation, because the reason why the one should be positively and the other ne electrified Suppose then that an observer stands at the and looks towards the north, and then turns his back t north and looks towards the south. In the first position regard the northern system of meteorological processes and in and in the second the southern. Now if symmetry obtain lutely in these systems that is to say, if the observer, wh regarded the northern or the southern system of things, either case precisely similar phenomena at his right hand his left then we should see no reason why the earth shou magnet, or why one hemisphere should be the seat of magn the one kind rather than of the other If then we regard m logical processes and motions as being in some way the terrestrial magnetism, we must direct our attention to that element which causes a want of perfect symmetry such as described in meteorological phenomena. This element ca be anything else than the rotation of the earth, which is f to right to an observer facing the north, but from right to l observer facing the south.

114. Now if we look upon the terrestrial meteorologica modified by the earth's rotation as having produced some cho past the magnetic state of the earth, it seems most na regard the system which formerly produced this magnetic being likewise that which at present maintains it in its ef and which also accounts for the various magnetic change take place It would seem therefore that terrestrial met and terrestrial magnetism are probably cognate subjects, a they ought to be studied together in the well-founded hope phenomena of the one will help us to explain those of the

Furthermore, if these meteorological processes derivi one sided character from the earth's rotation—are to be as accounting not only for the origin but for the mainte the earth's magnetic system, we can hardly fail to imag these processes must derive part of the energy which they from that of the earth's rotation. Tidal energy we know is from this source; but we must likewise regard part of th displayed in convection currents whether in the air or in t as derived no doubt from the same source. And we may allow that in the phenomena of tidal action, as well as in convection currents of the air and ocean, there may be, no a transmutation of actual energy directly through friction n but likewise a transmutation of it, ultimately perhaps in but first through the intermediate agency of electrical which serve to maintain the magnetic state of the earth produce magnetic changes.

Now if this be the case, if there be a large and complicated of tidal and convection currents all tending to change the energy of the earth ultimately into heat, whether directly friction or indirectly through the medium of electricity, it impossible with the present state of our knowledge to calcul the smallest pretensions to accuracy at what rate this transm is taking place, and hence at what rate the velocity of th rotation is being slowly diminished.

METHODISM

I Wesleyan Methodism

history of Wesleyan Methodism embrace (1) the Methodism of Oxford, which was strictly An lic dly rubrical, though it was also more than rubrical evangelical Methodism of the Wesleys after th ion (in 1738), of which the Wesleyan doctrin ion and sanctification were the minute to and ion, while preaching and the class meeting were th motive and organizing forces a movement wh Wesley's death had developed into a form contain least in embryo all the elements of a distinct organization although in it neral d ctrin iberate claims it purported to be only an unattach l l society and (3) Wesleyan Methodism in th of Wesley, which, by steps at first rapid and aft r though leisurely, distinct and consistently unfold dependent position and his own ultimate attainment as a church

Oxford Methodism The beginning in November 1729 John Wesley, returning to Oxford from Lincolnshire, where he had been serving his father a curate, found that his brother Charles, then at Christ Church, had gathered a number students to join him in observing weekly communion. John Wesley's reconsecration to God, his infant association. Then first dated the custom of the weekly communion was the immediate fruit of the Greek Testament with which they paired rubrical observance of fated hours for private devotion visitation of the sick, of the poor and of prisoners, instruction of neglected children. They never themselves adopted any common denomination but of the list of derisive names they received from without that "Methodists" prevailed, sobriquet the fitness of which, indeed, as descriptive of one mechanical and unspiritual feature of Wesley's character (which he impressed also on his followers), was undeniable.

The first Oxford Methodism was very churchly. Between 1733 and 1735, however, a new phase was developed. Its adherents became increasingly patristic in their theories and tendencies, and Wesley came much under the influence of William Law. In regard to this period of his history, Wesley himself says that he

> "set the bow too far by making antiquity the ultimate rule, as subordinate, rule with Scripture by clinging to the writings, by extending antiquity so far by which in practices to have been universal in the Church, but by so, by not considering that the [illegible] provincial could bind only that province and the [illegible] general only those provinces which represented them. But of those decrees were adapted to particular times and, consequently when the circumstances ceased, must bind even those provinces."

It was in 1736, during his residence in Georgia whither he had gone as a missionary of the Propagation Society, that he learnt those lessons. Notwithstanding his asceticism and his rubrical punctilios the foundations of his High Churchmanship were gradually giving way. When returned to England he had already accepted the doctrine of "salvation by faith," although he had not yet learned that view of the nature of faith which he was for years to teach for half a century. He had, however, written in the journal of his homeward voyage he tells us that, "in the ends of the earth,' that he "who went to America to convert others was never himself converted to God." In this result his Oxford Methodism came to an end.

The original Methodism of Oxford never at any one time seems to have numbered as many as thirty adherents. There was a set called "Methodists," but there was no organization, no common bond of special doctrine or discipline; there were habits and usages mutually expected upon, but there was no official authority, only personal influence. The general features of the fraternity, if such a unity it may be called, seem to suggest closer affinities with the "Tractarian" school in its earlier stages than with anything else in modern history, and the personal ascendency of John Wesley may remind us in some measure of the influence exercised a century later by Dr Newman. There was no more any germ of permanent organization in the Oxford Methodism of 1735 than in the patristic and "Tractarian" school of Oxford of 1833.

Methodism after Wesley's Conversion. John Wesley landed at Deal, on his return from Georgia, on February 1, 1738. His journals on the homeward voyage, says Miss Wedgewood,[1] "chronicle for us that deep dissatisfaction which is felt whenever an earnest nature wakes to the incompleteness of a traditional religion; and his whole life, compared with his two years in Georgia, makes it evident that he passed at this time into a new spiritual region." . . . . . "By Peter Bohler," in the hand of God," he writes in his journal, "I was, on March 4, fully convinced of the want of that faith whereby alone we are saved." This "conviction" was followed on March 24 in the same year (1738) by his "conversion."

Like most good men of that age in England, Wesley before he came under the influence of his Moravian friends had regarded faith as a union of intellectual belief and voluntary self-submission the belief of the creeds, submission to the laws of Christ and to the rules and services of the church, acted out day by day and hour by hour, in all the prescribed means and services of the church and in the general duties of life. From this conception of faith the element of the supernatural was wanting, but equally that of personal trust for salvation on the merits of Christ. The work of Bohler was to convince Wesley that such faith as this, even though there might be more or less of divine influence unconsciously mingled with its attainment and exercise, was essentially nothing else than an intellectual and moral act or habit, a human operation and result altogether different from the supernatural spiritual faith of a Christian. This conviction led him a few days afterwards to stand up at the house of the Rev. Mr Hutton, College Street, Westminster, and declare that five days before he had not been a Christian. When Bohler warned not thus to despise the benefits of sacraments and grace, he rejoined, "When we renounce everything and fly to faith and get into Christ, then and not till then, have reason to believe that we are Christians." It is true that for several years after this he remained High-Church

[1] One evidence of this is to be found in the early and wide influence of the various members of the Oxford Methodist company after their brief association at the university came to an end, in which way the Wesleys went: we know also the separate path which their friend Whitefield made for himself. John Clayton, the High Churchman, settled at Manchester, renounced the Wesleys and began their evangelical movement, and remained an unbending Churchman to the end. Benjamin Ingham became a great evangelist in Yorkshire, founded societies, and, with his societies or churches, took the decisive step of leaving the Church of England and entering the position of avowed Dissent. The saintly Gambold, a poet as well as a theologian and preacher, became a Moravian bishop. James Hervey was in after life a famous evangelical clergyman, but of "Low" and Calvinistic views. These were the chief of the Methodists of Oxford.

[2] *John Wesley and the Evangelical Reaction of the 18th C*

[3] A disciple of Zinzendorf, then in England on his way to A

his principles and opinions, but nevertheless his was dead at its roots.

xperience also made Wesley an evangelist. He rgotten gospel to preach, the gospel by which e to be converted, as he had been, and to be made reatures." And this result, this new birth, was ndent on any churchly form or ordinance, on any prerogative or service, or on any sacramental grace ence. To raise up, accordingly, by his preaching sonal influence, a body of converted men, who themselves become witnesses of the same truth by had been saved, was henceforth to be Wesley's . This was the explanation under which he great preacher, this also made him an organizer ving with success into classes and societies. In the the preaching power; in the class-room was the and personal influence. The vital link between ist and the class-meeting was the doctrine and e of "conversion." Thus Wesleyan Methodism d, not from Wesley the ritualist, but from Wesley ecluse.

y's doctrine offended the clergy. His popularity eacher alarmed them. The churches were soon inst him. He attended the religious meeting hurch of England basis which had existed in and elsewhere for fifty years, so far as there were to him, the Moravian meetings, and meetings in s of private friends, but these were quite nt for the zeal and energy of himself and his who had been "converted" a few days before. Accordingly in 1739, he followed the example Whitefield, and preached in the open air to immense. In the same year also he yielded to the urgency followers and to the pressure of circumstances, coming possessed of an old building called "the y," in Moorfields, transformed it into a meeting. Here large congregations came together to hear hers. About the same time, in Bristol and the ning colliery district of Kingswood, he found himged, not a little against his will, to become the premises for the purpose of public preaching and meetings. Here was the beginning of that vast of preaching houses and meeting rooms, all of them ly fifty years settled on Wesley himself, which, aving in any way belonged to the Church of , became, through Wesley, the possession of the st Connexion.

eligious societies through which the Wesleys, after nversion, exercised at first their spiritual influence part, as has been intimated, Moravian, that in ame of which the rules were drawn up by Wesley in 1738 (May 1), being the chief of these, and societies in connexion with the Church of England, e out of those which sprang up in the last years Stuarts, as if to compensate for the decay of sm within the church. In 1739, however, a strong of antinomian quietism gained entrance among the ns of England (Bohler himself having left for in the place of 1738), and Wesley, after vainly ing for a time against this corruption, found it ry formally to separate from them, and to establish y of his own, for which a place of meeting was provided at the Foundery. This was the first nder the direct control of Wesley, and herein was al and vital beginning of the Wesleyan Methodist , that is, of Wesleyan Methodism. Hence the ns celebrated their centenary in 1839. It was not, r, till 1743 that Wesley published the Rules of his

By that time not a few other local societies had ded to that at the Foundry, the three chief centres being London, Bristol, and Newcastle. Hence Wesley called his Society, when he published the "Rules" in 1743, the "United Societies." His brother's name was joined with his own at the foot of these Rules, in their second edition, dated May 1, 1743, and so remained in all later editions while Charles Wesley lived. Those Rules are still e rules of Wesleyan Methodism. Since Wesley's death they have not been altered. During his life only one change was made of any importance. In 1743 the offerings given weekly in the classes were for the poor, there being at that time no Conference and no itinerant preachers except the two brothers; after a few years the rules prescribed that the weekly contributions were to go "towards the support of the gospel." The Society is described as "a company of men having the form, and seeking the power, of godliness, united in order to pray together, to receive the word of exhortation, and to watch over one another in love, that they may help each other to work out their salvation." "The only condition previously required of those who desire admission into these societies" is "a desire to flee from the wrath to come, and to be saved from their sins." The customary contribution was a minimum of a penny a week or a shilling a quarter.

In 1739 these societies were not divided into "classes." But in 1742 this further step in organization was taken, and the change is recognized in the rules of 1743. Leaders were appointed to these classes, and became an order of spiritual helpers and subpastors, not ordained like lay elders in the Presbyterian churches, but, like them, filling up the interval between the pastors that "labour in the word and doctrine" and the members generally, and furnishing the main elements of a council which, in after years, grew up to be the disciplinary authority in every "society." In every society there was from the beginning a "steward" to take and give account of moneys received and expended. After a few years there were two distinct stewards, one being specially appointed to take care of the poor and the "poor's money," the other being, in general, the "society steward." And, finally,—though hardly, perhaps, during Wesley's lifetime,—in the larger societies there came to be two stewards of each description. The leaders and stewards together constituted "the leaders' meeting," of which, however the complete circle of functions grew into use and into recognition only by degrees. The Rules of the Society, which are strict and searching, relate to worship, to conduct, and to the religious life, but do not once mention or refer to the Church of England, the parish church, or the parish clergy. The only authority at first was the personal authority of the two brothers, exercised either directly or by their official delegates. After years had passed away the leaders' meeting came to have an important jurisdiction and authority, but its rights and powers were neither defined nor recognized until after Wesley's death. From first to last there is no trace or colour of any Anglican character in the organization. Moravians or Dissenters might have entered the fellowship, and before long many did enter it who had either been Dissenters or, at any rate, had seldom or never entered a church. What would to-day be called the "unsectarian" character of his society was, indeed, in Wesley's view, one of its chief glories. All the time, however, this "unsectarian" society was only another "sect" in process of formation. Wesley for many years before his death had seen that, unless the rulers of the church should come to adopt in regard to his society a policy of liberal recognition, this might be the outcome of his life work. And it would seem as if in his private confidences with himself he had come in the end at times to acquiesce in this result.

Still more decisive, however, was the third step in the

pment of Wesley's "Society." The clergy not only ed the Wesleys from their pulpits, but often repelled and their converts from the Lord's Supper. This rst done on a large scale, and with a systematic ess and persistency, at Bristol in 1740. Under circumstances the brothers took the decisive step of istering the sacrament to their societies themselves, r own meeting rooms, both at Bristol and at Kings. This practice having thus been established at Bristol, not likely that the original society at the Foundery rest content without the like privilege, especially as f the clergy in London acted in the same manner e at Bristol. There were therefore at the Foundery eparate administrations. Here then, in 1740, were f we include Kingswood, three—separate local es, formed, it is true, and both served and governed ained clergymen of the Church of England, but not ing to that church or in any respect within its ment. As thereafter during Wesley's life one of others, or some cooperative or friendly clergyman, most always present in London and in Bristol for ministration of the sacraments, these communions, once begun, were afterwards steadily maintained, the Supper being, as a rule, administered weekly. on Sundays and on week days full provision was for all the spiritual wants of these "societies," apart her from the services of the Church of England. ly link by which the societies were connected with hurch—and this was a link of sentiment, not an one was that the ministers who served them umbered among its "priests."

741 Wesley entered upon his course of calling out achers, who itinerated under his directions. To the es founded and sustained with the aid of these ers, who were entirely and absolutely under Wesley's al control, the two brothers, in their extensive ys, administered the sacraments as they were able. lpers only ranked as laymen, many of them, indeed, men of humble attainments and of unpolished ways. e ordinary reception of the sacraments the societies oral were dependent on the parish clergy, who, how ot seldom repelled them from the Lord's table. So r the ordinary opportunities of public worship they had no resource but the parish church. The simple in their preaching-room was, as Wesley himself l, defective, as a service of public worship, in some unt particulars; besides which, the visits of the nts were usually, at least at first, few and far n. Wesley accordingly was urgent in his advices junctions that his societies generally should keep to arish churches; but long before his death, especially tinerant preachers improved in quality and increased ber, there was a growing desire among the societies their own full Sunday services, and to have the ents administered by their own preachers. The oment of these preachers into ministers, and of the es into fully organized churches, was, if not the ble, at any rate the natural, result of the steps Wesley took in order to carry on the work that was nally opening up before him.

44 Wesley held his first Conference. The early Conferences iefly useful for the settlement of points of doctrine and e and for the examination and accrediting of fellow- rs. They met yearly. Conferences were a necessity for and became increasingly so as his work continued to grow m. It was inevitable also that the powers of the Conference, h for many years the Conference itself only existed as it sufferance, and only exercised any authority by the per- of its creator and head, should continually increase. The as that in 1784 Wesley could no longer delay the legal tion of the Conference, and that he was compelled, if he rovide for the perpetuation of his work, to take measures for vesting in trustees, for the use of "the people called ists," under the jurisdiction of the Conference as to the ment of ministers and preachers, all the preaching places property of the Connexion. The legal Conference was d consisting of one hundred itinerant preachers named by and power was given to the "legal hundred" continually first to fill up the vacancies in their own number, to a expel preachers, and to station them from year to year, no being allowed to remain more than three years in one stati

By this measure Wesley's work was consolidated into a religious organization, having a legally corporate chara large property rights. And yet Wesley would not allow t organization to be styled a "church." It was only a "— the "United Society"—the Society of "the people called [illegible] the "Methodist Society." And of its members were not probated Dissenters were by him reckoned as b to the Church of England, although a large and increa portion of them seldom or never attended the services church. The explanation of this apparent inconsistency Wesley admitted none to be Dissenters except such as w the eye of the law those who, "for conscience sake, re join in the service of the church or partake of the sa administered therein" and that he interpreted "the Ch England" to mean, as he wrote to his brother Charles, believers in England, except Papists and Dissenters, who b word of God and the sacraments administered among them

But Wesley was to carry his Society to a yet higher development and one which made it still more difficult to [illegible] its character from that of a distinct and separate In 1738 Wesley had been three times a High Churchman some time even after he had entered upon his course of t and independent evangelism he continued to hold, in the High Church view. But in 1746 he abandoned once his ecclesiastical High Churchmanship, although he never either a political or a Jurisdictarian Low Churchman, standard and manner of the 18th century. He relate journal under date January 29, 1746 how his views were tioned by reading Lord Chancellor King's account primitive church. From that time forward he consistently tained that the "uninterrupted succession was a fable w man ever did or could prove." One of the things taught Lord King's book was that the office of bishop was origin and the same with that of presbyter, and the practical which Wesley drew was that he himself was a "Scriptural pos," and that he had as much right as any primitive or mo bishop to ordain ministers, as his representatives and help should administer the sacraments, invested of himself, societies which had placed themselves under his spiritual The right, as he conceived it to be, he held in abeyance fo forty years, but at length he was constrained to exercise by so doing, in effect led the way toward making his S distinct and independent church.

In 1784 the American colonies having won their indepe it became necessary to organize a separate Methodism for where Methodist societies had existed for many years gave formal ordination and letters of ordination to Dr Coke, a presbyter of the Church of England, a superintende bishop for America, where Coke ordained Francis As presbyter and superintendent (or bishop) and Coke and together ordained the American preachers as presbyters. that ordination date the ecclesiastical commencement of A Episcopal Methodism, in which the bishops are only chie the presbyters whom they superintend, superior in [illegible] bu same order. The Episcopal Methodism of America repres day the largest aggregate of Protestant communicants and pers of the same ecclesiastical name to be found in any on in the world.

The following year (1785) Wesley ordained ministers f land. These ministers were quite outside of the est Presbyterianism of the day, with its lukewarm "moder while the Scotch sect which had seceded from the state would hold no terms with Arminians like Wesley and he fo Hence Wesley was compelled to make special provision administration of the sacraments in Scotland. He t ordained some of his ablest and most dignified preach created them formally in his correspondence the s title of "Reverend," and appointed them to administer th ments north of the Tweed.

At length, in 1788, Wesley obtained a number of preach Tyerman says seventy, to assist him in administering the sa to the societies in England; and of these he ordained one der Mather) to be superintendent or bishop, his brother being now dead, and Dr Coke sometimes absent for long pe America. The number of societies which demanded to h sacraments administered to them in their own places of continually increased, and their claims were often too st be resisted, especially when the parish priest was either

societies came to be the universal rule. By this ion the preachers assumed the powers of pastors, rdance, however, only and always with the desire oice of their flocks. No formal service or act of ion was brought into use till forty years after- All preachers on probation for the ministry, he completion of their probation, were "received l connexion" with the Conference, this reception im investment with all pastoral prerogative. Modern lism has developed more fully and conspicuously toral idea.

ooner was the sacramental controversy settled than ther question as to the position and rights of th me to the front in great force. A comparatively arty, led by Alexander Kilham, imported into the ion ideas of a republican complexion, and demanded e members in their individual capacity should be zed as the direct basis of all power, that they should lect the leaders and stewards, that all distinction ference between minister and laymen should be way (elected laymen being sent as delegates from nits in equal number with the ministers), that they y should possess no official authority or pastoral ative, but should merely carry into effect the ns of majorities in the different meetings. In the of a very violent controversy which created pamphlets oadsheets, chiefly anonymous, from Kilham's pen, ting his views and containing gross imputations on nisters generally, and in particular on some not but distinctly indicated, were disseminated through ieties. The writer was tried at the Conference of condemned for the publication of injurious and fiable charges against his brethren, and by a majority vote expelled from the Conference. In the following a he founded the "New Connexion," the earliest of ganized secessions from Wesleyan Methodism.

s much more moderate than Kilham prevailed in nnexion at large. At the Leeds Conference of 1797 is was laid of that system of balance between the atives of the ministers and the rights of the laity has been maintained in it principles ever since, hich, in reality, has governed the recent provisions 78) for the admission of lay representatives into the ence not less than the former development of an Methodism. The admission of members into iety had, up to 1797, been entirely in the hands of nerant preachers, that is, the "assistant," hence o be styled the "superintendent," and his "helper." w regulations, without interfering with the power inisters to admit members on trial, declared that eaders' meeting shall have a right to declare any on trial improper to be received into society, and uch declaration the superintendent shall not admit erson into society"; also that "no person shall be d from the society for immorality till such immorality ved at a leaders' meeting."[1] For the appointment urch officers (leaders and stewards) the following ions were made, the second based on recognized the first on general but not invariable practice:

"1. No person shall be appointed a leader or steward removed from his office, but in conjunction with the leader ng, the nomination to be in the superintendent, and the tion or disapprobation in the leaders' meeting.

"2. The former rule concerning local preachers is confi viz., that no man shall receive a plan as a local preacher, the approbation of a local preachers' meeting."

The Conference at the same time made several pro for carrying out the process, which had been going some years, of denuding itself of direct responsibi regard to the disbursement of the Connexional The principle was established that such matters wer administered by the district committees acting in -pondence with the quarterly meetings of the circui was also provided that circuits were not to be without the consent of the respective quarterly me and, finally, it was resolved that, in the case of a rule made by the Conference for the Connexion, it within a circuit might be suspended for a year quarterly meeting, if it disapproved of the rule. ever, the Conference, after twelve months' interv adhered to the new rule, it was to be binding on the Connexion.

The powers of district committees, as defined by Conference, were confirmed and enhanced, power being given to call special meetings of the committee convened when necessary to settle the affairs of a di circuit. In the same Conference all the principa of Methodism, in regard both to the ministry and laity, were collected and (in a sense) codified, ma The new regulations adopted that same year, a whole, under the title "Large Minutes," was accep binding by the Conference, each minister being re to sign his acceptance individually. This compos itself based on one which had been prepared by W is still accepted by every Wesleyan minister on his tion as containing the rule and principles to wh subscribe. During the sitting of the critical Con at Leeds an assembly of delegates from bodies of t throughout the kingdom was simultaneously held form of the regulations enacted by the Conference a considerable extent, determined by the nature an of the representations made by this body of trustees was one request, however, which the Conference di declined to grant, namely, that lay delegates Conference. The Conference replied that they co admit any but regular travelling preachers into the and preserve the system of Methodism entire, partic the "itinerant plan." It was not many years wards that anything was heard again as to this ma

By the settlement now declared the outli Methodism as an organized church were fairly com Many details have since been filled in, and many c have been made in secondary arrangements, b principle of development have remained unchanged Connexion after 1797 had a long unbroken pe peaceful progress. The effect of the "Kilhamite tion," indeed, was after 1797 not greatly felt by the body. The number of Methodists in the United Ki in 1796, the year of Kilham's expulsion, was 95,3 1797 it was 99,519; in 1798 the New Connexion first Conference, and reported 5037 members, the of the parent body being 101,682. Nor was it t that the New Connexion reached 6000.

During the period of quiet growth and development followed 1797 the influence of one superior mind (J Bunting, 1779-1858) was to prevail with increasing swa was to be the period of the gradual development of lay co-o in the administration of the various departments of Con extension and enterprise, a development which prepared for the important legislation of 1852 and following years, the ultimate settlement of the respective provinces and

iod may be deemed as extending from the revolutionary
1791 97 to the epoch of political and municipal reform
, 1828 35, which coincides with a second period of politico-
tical agitation in Wesleyan Methodism
97 the Conference, as already mentioned, had refused to
ected laymen or lay delegates any place either in the
ce or in district committees. Within a few years after
owever, the practice grew up for the circuit stewards to
ne district committee ring the transaction of financial
, and in 1815 this was recognized in the Minutes of
ce as an established rule, and it was enacted that no
increase of the income of the minister should be sanctioned
Conference until approved by a majority of the district
ee during the attendance of the circuit stewards. Since
ption of this rule the lay element in the district committees
ably increased and developed. Another characteristic and
nt feature in the organization of Wesleyan Methodism,
rew into distinct form and prominence during the period
er review, was that of the administration of all the Con-
l departments (except such as were regarded as properly
, by means of mixed departmental committees, appointed at
ecessive Conference. These committees made recommenda
the Conference in regard to such new legislation as they
d, if desirable and to the appointment of the members of com-
and, for each department, a large committee of review, of
he members of the ordinary committee of management
he nucleus, came to be held each year immediately before
ference. In the committees the number of ministers and
en were equal. On the principle, between 1811 and 1835,

to the development of the position and claims of the
In 1818 the usage of the Conference was conformed to what
g been the ordinary unofficial custom and the preachers
be styled in the *Wesleyan Methodist Magazine* and in
ficial publications "Reverend," a fact which may
but which in reality was of important significance.
34, after the idea had been long entertained and the project
n repeatedly discussed, it was determined to establish a
al institution for the training of ministerial candidates.
e now four colleges, with two hundred and fifty students
the practice of ordination by imposition of hands was

ual ince, however, as these in the general organization
elopment of the Connexion, and especially in the status
ofessional training of the ministers, could not be made in
body without offence being given to some, whose tendencies
disallow any official distinction between the ministry and
y, and who also objected to the use of the organ. This
g element was strong in the West Riding of Yorkshire, and
on the placing of an organ in Brunswick Chapel, Leeds,
trustees with the consent of the Conference, a violent
n broke out. The consequence was a disruption, the first
of, under the title "Protestant Methodists." But this
ended, some years later, in a more considerable
t, the Connexion was in 1828 entering on a period of agita
the current of political affairs was approaching the rapids of
he Reform Act marked the centre and the point of maximum
ent. A body like Wesleyan Methodism could not but feel
ence the excitement of this movement. It is true that Wesleyan
never been political, that few of its members
ed electors, and that the ministers and the better
of the "Societies" were strongly Conservative in their general
Nevertheless the democratic element of the community shared in the
movement of the time, and the Conservative tone of the
ts and of the mass of the society to do duty was not in full har-
with the popular spirit of the people generally. Accordingly
ments of disturbance, which only partially exploded in the
stant Methodist secessions, continued to make themselves
different parts of the Connexion, during the following years
ical controversy. The decision of the Conference in 1834 to
a college for the training of ministerial candidates gave
offence to the malcontents. Such an occasion was all that
ting for the various discontents of the Connexion to gather
d. The demands made by these agitators proceeded on a basis
ratic ecclesiasticism such as it is very difficult to apply suc-
to a system of associated churches. The result was a third
n, based on the same general ground of ecclesiastical prin-
s the two preceding, which was organized in 1836, and with
new secession was known first as the "Wesleyan Methodist A
tion"; but for a number of years past it has been merged i
larger body of seceders designated "The Methodist Free Chu
Its leader at the first was the Rev. Dr Warren, who left it, h
not many months after it was formed, and took orders in the
of England.[1]

The controversies of 1835–36 left their mark on the leg
and official documents of the Connexion. The principles
remained intact, some further guards only being added to
any danger of hasty or irresponsible action on the part o
intendents, and at the same time "minor district meetings
organized in order to facilitate appeals. One error was, h
committed by the Conference. In 1797 no provision had be
for bringing the circuit, through its quarterly meeting, int
relations with the Conference. In 1836 a right of direct m
to the Conference was given to the circuit quarterly meeting
was so fenced round with conditions and limitations as to
practically inoperative, and at the same time provocative
picion and irritation.

The effect of the secession of 1836 on the general progres
Connexion was not great. The number of members repo
1835 in Great Britain and Ireland was 371,251 (there
decrease in England of 951), in 1836 381,369, in 1837 384,7
the next ten years the advance of the Connexion in number
general prosperity was apparently unprecedented. The Ce
Fund of 1839 40 amounted to £221,000. In the midst, h
of all the outward prosperity of Methodism partly perhaps
sequence of it very perilous elements were at work. The
tionary ideas of the Chartist period (1840-48) and of Con
politics (1848 49) reacted on Wesleyan Methodism as the
ideas of 1791 and of 1851 had done at those epochs. The
of old controversies- ecclesiastical, quasi political, and pe
still smouldered, and at length burst into fresh flame. Fr
a strong spirit of opposition to the leaders of the Connexi
especially to Dr Bunting, was fanned by the circulation of
mous "fly leaves" of a very scurrilous character. At th
time the policy of the Conference and of the ministers in t
cuits had proceeded more than was wise on the old line
general administration relied too much on the footing of
confidence on the part of the people and on the power o
prerogative in the hands of the minister. The memorial
1836 was indicative of the too exclusive spirit of pastoral
ment which had prevailed. The wisdom of Dr Bunting
five and twenty years led the way in gradually liberalizing
polity and the policy of Methodism, and adapting them
changing conditions of the times. But this wisdom seems
found its limits before 1849, when the internal dissensions
their climax. In that year James Everett, the chief autho
fly sheets, and two other ministers, Samuel Dunn and
Griffith, who had identified themselves with him, were e

till after the Conference of 1850. The union of the "M
Free Churches," in which was incorporated the "W
Association" (of 1836), was formed by the seceders. The
Connexion" also received some thousands of the seceders
ranks. But by far the greatest part of those who left wo
neither of these bodies.

Between 1850 and 1855 the Connexion in Great Brit
Ireland lost 100,000 members, and not till 1856 did it
recover. In that year the numbers were returned as
showing a small increase over the preceding year. Since th
and unity have prevailed unbroken.

The convulsion of 1849 52 taught the Connexion, and
under the Conference, lessons of the highest importance.
the quarterly meeting was so defined as to make it the gre
sentative meeting of the circuit, including stewards, leade
preachers, and trustees. The right of memorial to the Co
was given to it in the widest and freest sense. These
bodies invite ministers to the circuits, or decline so to d
mine and pay their "allowances," as salaries to ministers
called in the Connexion, and review all the interests of the
spiritual or financial. They had also conferred upon them
the right to appoint a circuit jury of appeal from the ver
findings of a leaders' meeting in certain cases of discipline

nished by the Wesleyan Missionary Society. The last st return showed 1769 members, 126 members on trial, 27 m 1 minister on trial, and 3 supernumerary or retired ministe British Conference has a right of veto as to certain points lation in the case of affiliated Conferences.

Australasian Methodism was for more than twenty yea an affiliated Conference, dating from 1851. Since 1876, t the Australasian Conference has been independent. The Conference meets once in three years, having under it our Conferences—one for New South Wales and Queensland, and Victoria and Tasmania, a third for South Australia, and a for New Zealand. These Conferences—the general and the a are all mixed and representative after the same general pa the British Conference. They have also under their charge part of their Connexion, the Wesleyan missions in Tonga which were begun by the parent body before the original a yearly Conference for Australasia was organized. The nu 1881 were for the Methodism of Australia 28,310 membe 363 ministers, and for the South Sea missions 35,111 memb 16 missionaries of Europe in blood and a very large nu native ministers and assistant ministers.

Canadian Methodism was also affiliated till 1873, when it an independent Connexion. It includes six provincial ann ferences and one General Conference which meets every thr The General Conference is mixed and representative, the Conferences are purely ministerial. Canadian Methodism a powerful position in the Dominion. It numbers as nearly be ascertained about 110,000 members and is strongest in Canada. It possesses a university—the Victoria Unive Upper Canada.

The Doctrines of Methodism.—In doctrine all br of Methodism are substantially identical. W doctrines are contained in fifty three sermons kn the "four volumes" and in his *Notes on the New Tes* The Conference has, however, published two cate one for younger the other for older children, of w new and carefully revised edition has lately been comp In general, Wesleyan theology is to be described a system of evangelical Arminianism. In par Wesleyan divines insist on the doctrines of origi general redemption, repentance, justification by fa witness of the Spirit, and Christian perfection,—t has been customary for Methodists to say, the doctr a "present, free, and full salvation." By the wit the Spirit is meant a consciousness of the Divine through the atonement of Jesus Christ. Wesleyan often been represented as holding the Calvinistic d of "assurance." The word, however, is not a W phrase, and assurance, so far as it may be said to be by Methodists, signifies, not any certainty of final sa but merely a "sense of sin forgiven."[2]

II. American Episcopal Methodism.

The beginnings of American Methodism are trace the year 1766, when a few pious emigrants from introduced Methodism into New York. On recei appeal in 1768 from the New York Methodists, wh engaged in building a preaching house, Wesley laid t of America before the Conference at Leeds; in 17 two preachers, Boardman and Pilmoor, volunteered to the colonies. Boardman went to New York, P to Philadelphia. In 1771 two other Methodist itin Francis Asbury—the most famous name in Am Methodism—and Richard Wright, went out to A In 1773 Thomas Rankin, a preacher of experience

[3] For the history and constitution of Wesleyan Methodism the follo may be consulted:—Wesley Works, especially his *Journal*; Southey Tyerman's *Wesley*; Rigg's *Living Wesley*, and *Character and Life of Jo* Jackson's *Life of Charles Wesley*; *Minutes of Conference*, Vol. I., 17 George Smith, *History of Wesleyan Methodism*, 3 vols.; Dr Abel Steven *of Methodism*, 4 vols.; Pierce *Polity of Methodism*, Dr Williams' *Ch and Polity of Wesleyan Methodism*, Rigg, *Connexional Economy*; *Minutes*, 1877 to 1881.

ley, held the first Conference in Philadelphia, when were 10 itinerant preachers and 1160 members. he breaking out of the War of Independence the Methodist preachers were unpopular, and all but Asbury went back to England. At the end of the owever, in 1784, Wesley sent out Dr Coke, and an Methodism was organized as an independent with Dr Coke and Francis Asbury as its presbyters. The history of American Methodism since that is too vast and complicated for any attempt to be o summarize it here. Methodism is more properly l in its character a n American church than any in the States. In Massachusetts and some other New England States it is less powerful than Con ough in, which fell from there much of its ancient supremacy, in the city of New York it is less powerful re by reason, and indeed, occupies a position less ly influential than might have been expected. But adelphia it is very powerful; so also in Baltimore Cincinnati. If not "home" in New York city it is here in the States, and generally throughout the and mid western States it is the prevalent form d than any other church.

The Methodist Episcopal Church Episcopacy is other Episcopal churches. The bishops are superintendents, presidents over the whole territory of Methodism in rotation, holding over the annual Conferences. These Conferences are ministerial. But the General Conference, which meets once years, and which is the Conference of legislation is lical, mixed and representative. The first General Conference in 1792 the initial delegated or representative Conference the first mixed or ministerial and lay General Conference. There were still but few districts assembling in the al Methodism of America, and now there are but few. The maintain the unity of the Connexion in the interval between al Conferences by their visitation and by their co-partnership with the Episcopal clergy. ministers also called presbyters supplement the action and superintendency of the bishops. e the over districts, holding all the circuit quarterly meetings, holding the district meetings at which such meetings have arged.

The Episcopal Methodism is distributed into five distinct churches, which, however differ from each other in no ry important particulars of discipline, government. The American Methodist Episcopal Church South separate organization in 1845 by reason of the slavery ry. The coloured churches, of which there are three, pendently from local causes. The following are the latest

	Ministers	Members
The Episcopal Methodist Church	1,112	1,091
The Episcopal Zion Church		
Methodist Episcopal Church		

Methodist Episcopal Church alone there are one hundred Conferences presided by twelve bishops. The church has ions, the heads of which some of distinguished ability. Its foreign missionary scene of the most recent and excited. The missionaries are in India, China, an. The Methodist Church South also has some influential ties, particularly that at Nashville, and has missions, in Japan and Mexico.

es these Methodist Episcopal churches, with their total of 00 church members, there are two other churches which do me the name at all, but are yet essentially Methodist in and discipline, not varying in any important particulars Episcopal Methodism of America. Of these one is called ed Brethren, with 15,000 members, the other the Evan- Association, with 113,000 members.[1]

Episcopal Americo-Methodism. The bodies included under l are chiefly secessions from the original stock of American sm, founded on principles of democratic church government, s to those of the English Methodist secessions. The only considerable body, however, is the Methodist Protestant with 125,000 members. The minor bodies, four in number altogether less than 60,000 members, the principal be American Wesleyan Church, with 25,000 members.

III. Other Methodist Bodies in Britain.

The bodies still to be noticed, while differing points of church government, agree as to doctri in general as to the means of grace and as to inner s fellowship with the parent "Connexion." Th maintain class meetings and love feasts, have l meetings and quarterly meetings, and largely emplo preachers.

The Methodist New Connexion was founded in 1797 Alexander Kilham, who died in 1798. Its general princi indicated above. Its statistics for 1881 were as follow ministers and 27,770 members including the 6 on missions bers 3882 on trial, and 74,744 Sunday scholars."

United Methodist Free Churches. This organization in its form must be identified with the Wesleyan Methodist As of 1836. That body first absorbed into itself, in great "Protestant Methodists" of 1828. It was afterwards gr created, and its organization in some points modified, when number of the seceders from the parent Connexion in 1850 it rank. The main body of its Conference does not consist, of the New Connexion, of an equal number of circuit minis elected circuit lay delegates; but of circuit delegates, ministerial or lay elected without any respect to office, m or other. Its circuits are independent of the contro Conference. The Connexional bond, accordingly, in this de tion is weak, and the itinerancy is not universal or uniform rule or its operation. The amalgamation between the W Methodist Association and the "Wesleyan Methodist Ref of 1850 took place in 1857. At that time the combined numbered 11,000. At present (1881-82) they number 72, cluding 7772 members on the mission stations, besides 7824 The number of ministers is 392, with 10 retired or "supernu merary." The number of Sunday scholars is 190,957.[3]

Primitive Methodism. In this earnest and hard-working nation the ministers, of whom some are women, are very "the servants of all." The Conference is composed, in add twelve permanent members, of four members appointed by ceding Conference, and of delegates from district meeting principle of proportion is that there should be two laymen member of "travelling preacher," and the "travelling pr have no pastoral prerogative whatever. The Conference is s and the Connexional bond is strong. This body was fou Hugh Bourne and William Clowes, local preachers w separated from the Wesleyan Connexion, the former in 1 latter in 1810, because of their violation of Conference reg as to camp meetings and other questions of order. The Co had, in 1807, pronounced its judgment against camp m which had been introduced into the country from America, Bourne and Clowes were determined to hold such m founded thus by zealous and "irregular" lay preachers, tive "Methodism, as the resulting new body called itself, h in its organization, its spirit, and its customs strong trac ancestry. It has been a very successful body, aiming simply evangelistic work, and is now numerous and powerful, nu among its ministers, not only many useful preachers, but marked originality and power and also of superior cul There has for many years past, if not from the beginning very friendly feeling between the old Wesleyan Connexion Primitive Methodists. Its latest statistics (1881-2) sho "travelling preachers" 185,312 members, and 388,350 scholars.[4]

Bible Christians. The Primitive Methodists sprang up midland counties, the Bible Christians in Cornwall. Thes resemble the "Primitives" in their character and spirit. founder was a Cornish local preacher called O'Bryan. He Connexion is often known as the Bryanites, and Cornish e have propagated this denomination widely in the colonie Conference is composed of ten superintendents of distr president and secretary of the preceding Conference, lay d one from each district meeting, and as many of the t preachers as are allowed by their respective district mee attend. In general it may be said that the ministerial members of the Conference are about equal in number. The for 1881-82 showed in England (chiefly the west and south

d in the Channel Islands 136 itinerant preachers, 21,209 s (besides 690 on trial), and 36,335 Sunday scholars. In the number of members was 6652, and in Australia and aland 3671.'

Wesleyan Reform Union is an aggregate of local Methodist churches, loosely held together by a Conference, and is he results of the great Methodist disruption of 1851-52. urns for 1881-82 showed 18 ministers and 7728 members.

enical Methodist Conference.—This Conference was held in ad Chapel, London, in September 1881. Representatives esent from all the Methodist bodies throughout the world, as estimated that these represented not less than 5,000,000 bers and 20,000,000 of population. Whilst in church tion these bodies differed, as has been shown above, in and in respect of their purely spiritual discipline and f grace, they were all agreed in principal matters. The ce was entirely practical in character. The object was to zeal and union among the constituent bodies as to all points of Christian sympathy and activity, at home and and especially as to home mission work, general philan Christian education, and a Christian use of the press. There representatives present from the Methodist bodies in all the world.[2]

Calvinistic Methodists.—Between the Methodism of Wales t of England there was never any other than incidental on. Indeed, although the name of the Welsh movement rowed from the English, not only was Welsh Methodism dependent in its origin, but in reality it s beginning, as an eal movement, was earlier than that of English Methodism. Vesleyan Methodism, furthermore, Welsh Methodism was out distinguished by the fact that it was Calvinistic in its . For some years Whitefield's name was placed by the of Welsh Methodism at the head of their movement, but nexion was not at any time much more than nominal, eld being, indeed, too often and too long together in to exercise any real presidency over the Methodism of the ality.

uction, however, must be made between Welsh Methodism rangelistic movement and as an organization. In its later tinctly organized form, its main elements date from 1811, he actual unity and the final consolidation of the organization om so recent a period as 1864. At that date we find the tic Methodism of North and of South Wales for the first ited in a common organization and government, and brought he supreme control of one "General Assembly."

spiritual awakening from which Welsh Calvinistic Methodived its earliest inspiration and impulse began in 1735 and most contemporaneously and quite independently, in three t counties of South Wales. Howell Harris, a gentleman of sition, born and bred at Trevecca in the parish of Talgarth, of Brecon, is the most prominent name connected with early Methodism. His first strong religious convictions and im ate from 1735. He was sent to Oxford in the autumn of that "cure him of his fanaticism," but remained only one term. return to Wales he began to exhort and preach in private and in such buildings as he could obtain the use of, being then oughout his life a simple layman. Of learning or theology but little; but he was an extemporary preacher of prodigious nce, and often of overwhelming power and pathos. While was thus preaching in the county of Brecon, Daniel Rowad been spiritually awakened at Llangeitho in Cardiganshire, men knowing nothing whatever of each other. Rowlands ordained clergyman, of some arning and of great ce. He was a pulpit orator, and refully prepared his l discourses. In Pembrokeshire, in, in that same year 3, Howell Davies began to preach the same doctrine in the pirit as the other two preachers, and ith effects scarcely, if less remarkable. The work thus gun in three distinct within the space of one year was strict connexion with tablished Church, and so continued to be throughout the tury. These single-minded preachers pursued their work es knowing nothing of the parallel work which Whitefield st begun in England. In 1738, however, Whitefield, in st of England, heard of Howell Harris, and in that year revivalists met in Cardiff. In 1739 Howell Harris had to extend his preaching tours far and wide, visiting not outh but North Wales, and, wherever he went, founding s societies in connexion with the Church of England, of a er resembling those called De Woodward's societies, which g been in existence throughout England, the chief difference hat the Welsh societies were "evangelical," Calvinistic, vivalist. It was in the same year that Wesley founded iety in England. In 1742 the clergymen connected with the Welsh movement were ten in number, and there were ing in concert with these forty lay "exhorters," as the called. In that year the first "association" of Welsh Calv Methodists was held at Waterford or Watford, in Glamorga Whitefield consented to preside, and joined his preach that of the Welsh evangelists. The first Calvinistic Me Conference was held at Waterford, under Whitefield's pres on January 5, 1743, eighteen months earlier than Wesley Conference. For a short time the Calvinistic Methodism of was linked to that of England. After 1748, however, Wh ceased to act as in any sense the official head of the Calv Methodists of England, and their organization, always loos gradually dissolved.

There was no Wesley in Welsh Methodism, and accordingly was no organic unity among the societies. Her Welsh M ism. Each local society was under the care of an "exhorte named layman. A number of these local societies were c together into a district, over which an "overseer" had chi also was usually an unpaid layman, though exercising n the function of a pastoral pastor. Sometimes, however, as case of Rowlands, he was a paid clergyman. The s attended their parish churches and there received the sacra The meetings or preachings held in the societies were called "house-to-house purposes."

In 1751 Howell Harris ceased to itinerate and retired to Tr From this time his leadership in the Methodist movement se have come to an end, and the movement languished for many after. Not till 1762 is any "revival" chronicled. In 1763 lands was obliged to quit his curacy at Llangeitho and bec Established Church. His people built him a chapel. He thu 1763, became a Dissenting minister, and, retaining his fa much of his power to the end of his course, he died in 1790.

Fifty years had now passed since the first victories of Methodism had been established by Howell Harris, and the ment, instead of having grown to strength and maturity, ap to have spent its force, almost in all directions, at least as any outward signs. But the Rev. Thomas of Bala was to be one of the chief means of reviving it. H the earlier Methodists, was a churchman, he had taken his at Oxford and served a curacy in Somersetshire. The door Established Church having been closed against him becaus style of preaching, he joined the Welsh Methodists in 17 his first sphere of marked influence was in North Wa he took a leading part in a great revival of which Bala From this pe may be dated the spring of Calvinistic Methodism, from which its later rise Charles zealously and successfully promoted the establishm "circulating schools" and of Sabbath schools. He was, the soul of the great Christian educating movement in Wale began in the last decade of the 18th century; and it was t his earnest zeal in seeking to provide Bibles for his Welsh especially the Sunday schools, that the British and Foreig Society was established. Though Methodism came the effectually rooted in the soil of Principality, was 1811 that the Welsh Calvinists took that step in the direc ecclesiastical independence which English Wesleyans ha sixteen years before by calling their preachers to the official of pastors and ordaining them to administer the sacraments.

From 1790 till almost the present time the work of g moulding the constitution of Welsh Calvinistic Methodi proceeded. The 'rules regarding the proper mode of con the quarterly association' were drawn up by Charles and upon in 1790. In 1801 the *Order and Form of Church Gov and Rules of Discipline* were published. In 1811, as h shown, ministerial ordination was initiated. In 1823 t *fession of Faith* was promulgated. And in 1864, as h already mentioned, the first "General Assembly" was h the two associations of North and South Wales respectiv united into one body. The constitution is now a modifie byterianism, each church managing its own affairs su successive appeal to the monthly meeting of the county quarterly association of the province, while the latter be refer the decision to the annual General Assembly.

The Welsh Methodists (or Welsh Presbyterians, as t now often called) have two theological colleges, one at B the other at Trevecca. They have also a foreign missionary with missions in Brittany, among their congeners of th race, and in Bengal.

In recent years this church has made great progress. In number of members was 58,678, in 1870 it was 92,735, and the returns showed 1171 churches, 118,979 communicants, Sunday scholars. The number of ministers is not officiall but is estimated at 600. The North and South Wales ass are now also known as synods.[3]

HODIUS, the apostle of the Slavs, was a native
salonica, and was born about the year 825. His
lity is unknown, but most probably he was a
ed Slav; the family of which he was a member
to have been one of considerable social distinction,
himself had already attained high official rank in
vernment of Macedonia before he determined to
n his secular career and embrace the monastic life.
unger brother Constantine (better known as Cyril,
ne he adopted at Rome shortly before his death)
o distinguished himself as a secular "philosopher"
stantinople before he withdrew to the cloister and
nde. Constantine about 860 had been sent by the
r Michael III. to the Khazars, in response to their
for a Christian teacher, but had not remained long
them; after his return to within the limits of the
, his brother and he laboured for the instruction of
avonic or Slavonicized population, especially by
of translations of the Scripture lessons and the
al book used in Christian worship. About the
3, at the invitation of Rastislav, king of "Great
a," who desired the Christianization of his subjects,
the same time that they should be independent of
mans, the two brothers went to his capital (its site
own), and, besides establishing a seminary for the
on of priests, successfully occupied themselves in
ng in the vernacular and in diffusing their religious
ne. After four years they seem to have received
epted an invitation to Rome from Pope Nicholas
had just been engaged in his still extant corre-
nce with the newly converted Bulgarian king, his
ecurred before their arrival, but they were kindly
l by his successor Hadrian II. Constantine died
e, but Methodius, after satisfying the pope of his
oxy and obedience, went back to his labours in
via" as archbishop of Pannonia. His province
s to have been, roughly speaking, co-extensive with
ins of the Raab, Drave, and Save, and thus to have
d parts of what had previously belonged to the pro
of Salzburg and Passau. In 871 complaints on this
were made at Rome, nominally on behalf of the
hop of Salzburg, but really in the interests of
rman king and his Germanizing ally Swatopluk,
av's successor; they were not, however, immediately
ful. In 879, however, Methodius was again sum-
to Rome by Pope John VIII., after having declined
up the practice of celebrating mass in the Slavonic
; but, owing to the peculiar delicacy of the relations
e with Constantinople, and with the young church
lgaria, the pope, contrary to all expectation, ulti-
decided in favour of a Slavonic liturgy, and sent
hius (880) back to his diocese with a suffragan
, and with a letter of recommendation to Swatopluk.
uffragan, a German named Wiching, unfortunately
quite the reverse of helpful to his metropolitan,
rough his agency, especially after the death of John
in 882, the closing years of the life of Methodius
mbittered by continual ecclesiastical disputes, in the
of which he is said to have laid Swatopluk and his
rters under the ban, and the realm under interdict.
ate of the death of Methodius is variously given;
ost trustworthy tradition says that it took place on
6, 885. He was buried at Welehrad (probably
eissenberg). The Greek Church commemorates St
on February 14 and St. Methodius on May 11; in
oman Church both are commemorated on March 9.

Schafarik's *Slawische Alterthümer*, where the original
ties are fully referred to. The subject of the present notice
probably not to be identified with the Methodius, a painter
nk, who, according to a well-known legend, converted Boris
aria by means of a picture of Christ's second coming.

METHYL, a chemical term which until lately wa
in two radically different senses, namely, as desig
either the atom-group CH_3, which in numberless ch
formula figures as a "radical" (compare CHEMISTR
v. p. 552), or a gaseous substance of the same compo
which, however, nowadays is generally called "dim
to distinguish it from the radical. A gas of the co
tion and the specific gravity ($C_2H_6 \div H_2 = 15$) corresp
to C_nH_n can be produced in two principal ways,-
by the decomposition of zinc-ethyl by water (Frankl

$$Zn(C_2H_5)_2 + 2OH \,.\, H = Zn(OH)_2 + C_2H_5H\ ;$$

and, secondly, by the electrolysis of acetate of
solution (Kolbe), we have virtually

$$2CH_3 \,.\, COOH = (CH_3)_2 + 2CO_2 \;\Big|\; {}^{+H_2\,.}_{-}$$
$$\qquad\qquad\qquad\qquad\quad {}^{+\text{pole.}}\qquad\quad {}^{-\text{pole.}}$$

These two gases used to be distinguished as two di
substances, Frankland's being looked upon as hyd
ethyl, $C_2H_5 \,.\, H$, Kolbe's as "real methyl" (CH_3)
until Schorlemmer proved their identity by showin
both, when treated with chlorine, yield the same id
chloride of ethyl, $C_2H_5 \,.\, Cl$. This confirmed th
generally adopted notion that the radical ethyl i
nothing but methylo-methyl, $H_3C - CH_2$*, so th
filling up of the gap* by an H must necessarily p
"hydride of ethyl" and "dimethyl" in one. The
methyl" which chemists used to dream of, and which
treated with chlorine, would yield two CH_3Cl's an
to $HH + ClCl = HCl + HCl$, does not, and according
present knowledge cannot, exist. A quasi apology f
"marsh gas," CH_4, the principal component of t
mixture which bubbles up from any marshy pond w
mud is stirred up with a stick. It is always pr
when vegetable matter decays in the presence of
and in the relative or absolute absence of air.
everybody knows as "fire damp" is nothing but a
sarily explosive) mixture of air with impure mar
produced in the constantly progressing metamorpl
the coal deposits; in certain districts streams of ma
are issuing forth from cracks in the earth; the "hol
of Baku is such a marsh-gas spring, which, havin
caught fire by accident, continues burning to th
Perfectly pure marsh gas can only be obtained fro
methyl, $Zn(CH_3)_2$, by its decomposition with wate
supra); a nearly pure preparation is procurable by
a mixture of acetate of potash or soda and caustic a
dull redness:-

$$\underset{\text{Acetate.}}{CH_3 \,.\, COONa} + NaOH = \underset{\text{Carbonate.}}{Na_2CO_3} + CH_3H\,.$$

Marsh gas can be prepared synthetically by the
of bisulphide of carbon vapour and sulphuretted hy
(both producible from their elements) on red-hot
$CS_2 + 2H_2S + 8Cu = 4Cu_2S + CH_4$ (Berthelot). A r
of marsh gas and chlorine, when exposed to direct su
explodes with formation of hydrochloric acid an
coal. In diffuse daylight only part of the hydr
eliminated and "replaced" by its equivalent in cl
which in general leads to the formation of four
$CH_3Cl = CH_4 + Cl_2 = HCl$, chloride of methyl; C
chloride of methylene; $CHCl_3$, chloroform; CCl_4
chloride of carbon. Of these several chlorometha
they are called, the first here interests us more th
of the rest, because from it any other methyl co
can be produced by the substitution of the proper
radical for the Cl of the CH_3Cl. Thus, for insta
can convert it into methyl-alcohol by treating the
with aqueous caustic potash at 100° C. (Berthelot)
is a most important synthesis, because it is this
alcohol that, in practice, always serves as the
point in the preparation of other methyl compound

Methyl-Alcohol.—This substance, in ordinary p

r made synthetically, but simply extracted from
pirit, a commercial substance which is produced
ially in the dry distillation of wood. The wood-
s contained in the aqueous portion of the tar pro
n this operation, along with acetic acid. To recover
he tar-water is neutralized with lime and distilled,
he acetate remains, while the spirit distils over,
with a deal of water, which, however, is easily
d, as far as necessary, by redistillation and rejection
less volatile parts. The "crude" wood-spirit, as
otained, is not unlike in its general properties to
y spirit of wine, from which, however, it is easily
uished by its abominable smell. The ordinary
cial article, besides a variable percentage of water,
s from 35 to 80 per cent. of methyl alcohol; the
nsists chiefly of acetone, but besides includes
yl-acetal, $C_3H_4(OCH_3)_2$, acetate of methyl, and
us other minor components. In Great Britain
uantities of wood spirit are used for the making
pylated spirit, a mixture of ordinary spirit of wine
ne-ninth of its volume of wood-spirit, which is
to be sold duty free for the preparation of
es, and for other industrial purposes. In former
here as elsewhere, wood spirit itself used to be
ed as a cheap substitute for spiritus vini; but this
nger so, since the aniline-colour industry has created
demand for pure methyl alcohol. Hence in some
ntal works the wood spirit, instead of being sent
such, is being worked up for its components, by the
ng sequence of operations:—(1) dehydration by
(2) heating, under an inverted condenser, with
soda, to convert the acetate into hydrate of methyl;
truction of the bad smells by mild oxidation; (4)
tion in a kind of Coffey's still, whereby it is split
approximately pure alcohol, acetone, and "tails."

ew industry led to the invention of the following technical
for the determination, in a given spirit, of the percentages
ethyl-alcohol and of acetone.

lcohol is determined by saturating 5 c.c. of the spirit with
e acid (volatilization of alcohol and iodide of methyl being
by means of a cold-water bath and an inverted condenser),
product poured into water. Iodide of methyl separates
heavy oil, which is measured as it is. According to direct
c.c. of pure methyl-alcohol yields 7·45 c.c. of crude iodide
Kramer and Grodzky).

e determination of the acetone the following reagents are
(Kramer):—(1) a solution of iodine, prepared by dissolv-
·254 grammes of iodine, by means of (say) 500 grammes
of potassium, in water, and diluting to 1 litre; (2) a
of caustic soda containing twice (NaOH) grammes per litre;
ol-free ether. Ten c.c. of the soda are placed in a gra-
ylinder and mixed intimately, first with 1 c.c. of the spirit,
h 5 c.c. of the iodine solution. Iodoform separates out (if
is present) in minute yellow crystal plates; this product is
out" by means of 10 c.c. of ether, and determined by
ing an aliquot part of the ethereal layer in a tared watch-
dryness and weighing the residue. C_3H_6O yields CHI_3;
part of iodoform indicates 0·28 parts of acetone.

formula of methyl-alcohol and its true chemical
er were correctly ascertained by Dumas and Péligot
y as 1834; yet pure methyl-alcohol may be said to
een an unknown substance until 1852, when Wöhler
us to prepare it, by first extracting the CH of the
H in the wood-spirit as oxalate of methyl, and then
posing the (purified) oxalate with water.

most convenient raw material to use nowadays is the
cial "pure" alcohol; if wood-spirit is employed it had
rst be purified by distillation over caustic soda (*vide supra*).
mation of the oxalate then is best effected (according to
er Watt) as follows:—500 grammes of oxalic acid crystals
ed with 200 c.c. of oil of vitriol; then 500 c.c. of the
e added, the whole kept for a time at 80° C., and then
to stand cold for twenty-four hours.
arge crop of oxalate crystals—partly $(CH_3)_2C_2O_4$, partly
C_2O_4—is separated from the liquor by pressure and subse-
quent drying over vitriol, and then decomposed by distillat
water.

The aqueous alcohol thus obtained is dehydrated by t
known methods used in the preparation of ordinary absolute

According to Kramer, a purer preparation than Wo
obtained by extracting the methyl as formiate instead of as
which is easily effected by digesting the wood-spirit with
acid of 1·22 specific gravity, and purifying the formic e
fractional distillation. This ether boils at 32°, the oxalate
C., hence a proper combination of the two methods sh
infinitely superior to either. What now follows must, in ge
understood to refer to Wohler's preparation.

Pure methyl-alcohol is a colourless liquid simila
general properties, in its behaviour to other che
inert liquids, and in its action as a solvent to o
absolute alcohol, from which, however, it differs
entire absence from it of all spirituous odour.
paration which smells of wood-spirit may be con
at once as impure. According to H. Kopp, its
gravity is 0·8142 at 0° C. and 0·7997 at 16·4.
volume at t° be V, then (from 0° to 61°)

$$V = 1 + 0{\cdot}001187\,t + 1{\cdot}361 \times 10^{-6}\,t^2 + 8{\cdot}711 \times 10^{-9}\,t^3$$

The boiling point is 64·6 to 65·2. The tension cur
determined by Regnault and by Landolt; but the
of the two observers do not agree except (approxi
at P = 760 mm. Methyl alcohol has quite a charac
tendency to "bump" badly on distillation, which, ho
can be prevented by addition of a small fragment
sodium, which produces a feeble but sufficient cu
hydrogen. Its specific heat is 0·713; latent heat of
264; combustion heat, 5307 per unit weight (Fav
Silbermann). The refractive index for the D (s
ray is 1·3379 + ·0013 for 10 + 5° C. (Dale and Gla

Methyl-alcohol mixes with water in all proportio
contraction.

Since Wohler's discovery a table for the specific gra
aqueous methyl alcohols has been constructed experimen
A. Dupré, but unfortunately his alcohol boiled at 58·7, a
sequently must have been something different from what g
goes by this name.

In its chemical reactions methyl alcohol, $CH_3.$
very similar to ordinary (ethyl) alcohol, $C_2H_5.O$
consequently, in the same sense as the latter, analo
water, H.OH. Thus, for instance, metallic sodi
potassium dissolve in ether alcohol with evolut
hydrogen and formation of ethylates or methylates
alkali metals. Example:

$$CH_3OH + Na = CH_3.ONa + H.$$

The two methylates crystallize from the solutio
crystal alcohol, which can be driven off in an atm
of hydrogen by heat, without decomposition of th
themselves. Water at once decomposes them into
alkali and alcohol, $CH_3.ONa + H.OH = NaOH + C$
Yet the reverse reaction takes place when the al
treated with a large excess of caustic soda.

The action of acids on methyl alcohol is in
quite analogous to that on, for instance, caustic sod
this important difference, however, that what in t
of NaHO goes on so readily in aqueous solution
$CH_3.OH$ succeeds only under circumstances pre
the accumulation of water. In these circumsta
have, for instance,

(1) $\overline{CH} + OH.CH_3 - H_2O = Cl.CH_3$;

(2) $(C_2H_3O_2)H + OH.CH_3 - H_2O = C_2H_3O_2.CH_3$;
Acetic acid. Acetic ether.

and so on with all monobasic acids. A dibasic acid
may act as $(X)H_2$ or as $(XH).H$; thus, for instanc

(3) $(C_2O_4H)H + OH.CH_3 - H_2O = C_2O_4.HCH_3$;
Oxalic acid. Methyl oxalic acid.

(4) $(C_2O_4)H_2 + 2OH.CH_3 = 2H_2O + C_2O_4.(CH_3)_2$
Methyl oxalate.

asic acid forms two methyl acids and one neutral
e have, for instance,

m PO_4H_3; $PO_4(CH_3)H_2$; $PO_4(CH_3)_2H$; $PO_4(CH_3)_3$.

ld, however, be a great mistake to suppose that
for instance (Ex. 3 and 4), the monomethyl or
thyl compound is formed depends on the quantity
l alcohol employed per unit of acid. This depends
largely on other conditions, as will be illustrated
paragraph. The methyl salts of oxygen acids are
ters, in opposition to the chloride, bromide, iodide,
and oxide, which are set apart as ethers. Broadly
, ethers are not, while esters are, readily decom-
y water into their components; but the nitrate
) behaves in this respect like an ether.

with Sulphuric Acid.—Methyl-alcohol mixes with
riol with considerable evolution of heat and (always
tial) conversion of the two ingredients into methyl
acid. Equal volumes of acid and alcohol give
eld. To prepare pure methyl sulphates, dilute
ture largely with water, avoiding elevation of
ure (which would regenerate the ingredients), and
with carbonate of baryta. Filter off the sulphate
to obtain a solution of the pure methyl sulphate
$_2$.Ba (where Ba = 137 eq.), from which this
sily obtained in crystals. From the baryta salt
r methyl sulphate is readily obtained by double
sition with a solution of the respective sulphate;
itself, for instance, by means of sulphuric acid.
r temperatures the reaction between vitriol and
lcohol results in the formation of methyl-ether,
, or of normal sulphate of methyl, $(CH_3)_2SO_4$.
r is a gas condensable into a liquid which, under
of one atmosphere, boils at −21° C.

dissolves in about one thirty-seventh of its volume of
more largely in alcohol and in ether; most abundantly
vitriol, which dissolves about six hundred times its
methyl-ether gas, thus affording a very handy means
g up the gas for use. The solution need only be diluted
n volume of water to be broken up into its components
ver).

ied oxide of methyl is now being produced on the
urious scale, and sold as a powerful refrigerating
One part of sulphuric acid is mixed with a little
part of dehydrated wood spirit, and the mixture
125° to 128° C. (130° being carefully avoided),
ethyl ether goes off. When the mixture is
d, more wood spirit is added to the residue so as
blish the original specific gravity (of 1·29), and
ing resumed, which again furnishes a supply of
and so on. This proves that the process is not, as
e supposed, one of mere dehydration, but a cycle
ns analogous to those in the ordinary process of
ation, as shown by the equation:—

$_4H_2 + CH_3OH = SO_4.HCH_3 + H_2O$.

$O_4 + H.CH_3 + H.O.CH_3 = SO_4(HH_2)(CH_3).O.CH_3$.

ter, $SO_4(CH_3)_2$, though obtainable by distillation of the
ith 10 parts of vitriol, is more conveniently prepared from
hyl sulphuric acid by distillation in vacuum at 130°–140°
$= 2SO_4CH_3.H + SO_4H_2 + SO_4(CH_3)_2$. It is a colourless
melling like peppermint, specific gravity 1·327 at 18°; it
87° to 188° C.

ide of methyl, CH_3Cl, readily produced by the action
chloric acid gas and hot methyl-alcohol (preferably
resence of chloride of zinc as an auxiliary dehy-
is a gas which, under ordinary pressure, condenses
uid at −23° C. The gas, at ordinary temperatures
very readily soluble in alcohol), is only sparingly
by water, which, however, at 6° unites with it
solid hydrate. Condensed methyl chloride has
an article of commerce, being largely produced
nethylamine (*vide infra*) and used as a powerful
frigorific agent, as well as for the extraction of perfumes from flowers. Regarding nitrite of methyl, NO—O—CH_3, its interesting isomeride nitromethane, O_2N-CH_3, and nitrate of methyl, NO_3CH_3 we must refer to the handbooks of organic chemistry.

Iodide of methyl, CH_3I, is obtained by distilling methyl-alcohol with hydriodic acid, which latter is best produced off-hand by addition to the alcohol of iodine and amorphous phosphorus. It is a colourless liquid of 2·269 specific gravity, boiling at 42·5° C., insoluble in water.

Organic Methyl Esters.—The more volatile ones are in general easily obtained by distillation of the respective acid with methyl-alcohol, or with methyl-alcohol and oil of vitriol (virtually $SO_4.H.CH_3$); the less volatile ones more conveniently by passing hydrochloric acid gas into a methyl-alcoholic solution of the acid. We have no space for the individual substances; but the salicylate $C_7H_5O_2.CH_3$ may just be named as being the principal component of the essential oil of *Gaultheria procumbens* (wintergreen oil).

Methylamines.—The general result of the action of ammonia on an ester is the formation of alcohol and acid amide. Example—

$$\underset{\text{Acetate of methyl}}{(C_2H_3O).O.CH_3} + HNH_2 = CH_3.OH + \underset{\text{Acetamide.}}{C_2H_3O.NH_2}.$$

With iodide of methyl this reaction is an obvious impossibility; what really takes place (as A. W. Hofmann has shown for this and all analogous cases) is that the iodide unites with the ammonia into the HI compound $HI.NH_2CH_3$ of a base NH_2CH_3, which can be separated from the acid by distillation with caustic potash, and when thus liberated presents itself as a gas surprisingly similar (almost to identity) to ammonia. The analogy extends to the action on iodide of methyl, which, in the case of methylamine, NH_2CH_3, leads to the formation of dimethylamine, $NH.(CH_3)_2$; and from the latter again trimethylamine, $N(CH_3)_3$, can be prepared by a simple repetition of the operation. These three amines are closely analogous in their chemical character to ammonia, the points of difference becoming the more marked the greater the number of (CH_3)'s in the molecule. Trimethylamine, having lost all its ammonia hydrogen, cannot possibly act upon iodide of methyl like its analogues. What it really does is to unite with the iodide into "iodide of tetramethyl-ammonium," $I.N(CH_3)_4$, analogous to iodide of ammonium, INH_4, we should say, if it were not the reverse, because the organic iodide (unlike its prototype, which is an ammonium compound only in theory), when treated with moist oxide of silver (virtually with AgOH), really does yield a solution of a true analogue of caustic potash in the shape of hydroxide of tetramethyl-ammonium, $N(CH_3)_4.OH$.

In regard to the actual preparation of these several bodies, which is not so simple as might appear from our exposition of their mutual relations, we must refer to the handbooks of organic chemistry. But we must not omit to state that trimethylamine, which only the other day was never seen outside a chemical museum, is now being manufactured on a large scale, and promises to play an important part in industrial chemistry. The waste liquors obtained in the distillation of alcohol from fermented beet-root molasses serve as a raw material for its preparation. These liquors, when evaporated to dryness and subjected to dry distillation, yield, besides tar and gases, an aqueous liquid containing large quantities of ammonia, acetonitrile, methyl alcohol, and trimethylamine. This liquor is neutralized with sulphuric acid, and distilled, when the nitrile and the methyl-alcohol distil over, to be recovered by proper methods. From the mixed solution of the sulphates of ammonia and trimethylamine the former is separated out as far as possible by crystallization; the mother-liquor

cilled with lime; the volatile bases are absorbed in chloric acid; the hydrochloric solution is evaporated; ne sal-ammoniac which comes out at first is, as far as le, fished out. The last mother-liquor is evaporated yness, and in this form represents commercial hylamine hydrochlorate. It is this product which for the preparation of methyl chloride (*vide supra*), ocess being founded upon the fact that a concentrated n of the salt, when heated, breaks up $3HCl \cdot N(CH_3)_3$ $N(CH_3)_3$ of free trimethylamine + $NH_4 \cdot CH_3HCl$ of chlorate of monomethylamine and $2CH_3Cl$ of methyl de.

se processes are being carried out industrially by nt in France. But this base trimethylamine seems ed to do more than provide us with a new refrigerat ent. The attempt has been made—it would appear, success—to utilize it for the preparation of pure ate of potash from native chloride of potassium, s ordinary ammonia, in the famous ammonia soda s, serves for the conversion of common salt into soda

yl Cyanides.—There are two distinct bodies which, by com- n and by synthesis, are both $CH_3 + NC$; they are named nitrile" (formerly called simply cyanide of methyl) and ide of methyl or methylcarbamine respectively.

onitrile was discovered by Dumas in 1847. It may be pre- by the distillation of a mixture of methylsulphate and of of potassium; but is obtained more easily and in a purer distilling acetamide with phosphoric anhydride. Acetate onia may be used instead of the amide, but it does not work

$CH_3 \cdot CO \cdot O(NH_4)$	$CH_3 \cdot CO \cdot (NH_2)$	$CH_3 \cdot CN$

Ethylamine.

er case we pass from a monocarbon to a dicarbon body, y from methyl to ethyl alcohol.

isocyanide is prepared by heating iodide of methyl with e of silver (CH_3I; $2NCAg$) and ether in a sealed up tube to 140°, to produce the crystalline body $AgNC + NCCH_3$, and The double cyanide, when distilled with some water and e of potassium, breaks up into its components,—the $NCAg$ g $(NC)_2AgK$; and the cyanide of methyl distils over. It is a ss liquid, characterized by quite an unbearably irritating and ng smell. The specific gravity is ·756 at 14°, the boiling point It combines with hydrochloric acid into a crystalline salt s readily decomposed by water into methylamine and formic Whence we conclude that in this case the cyanogen is tied nethyl by its nitrogen; thus:—

$$C\{N—CH_3\} + 2H_2O = H \cdot COOH + NH_2 \cdot CH_3.$$
Formic acid. Methylamine.

thyl here remains methyl, being separated by an N from the on-carbon, which latter passes into formic acid.

must not close this section without at least referring to *ethylphosphines*, as being a set of bodies related to PH_3 hine) as the methylamines are to NH_3 (ammonia), and similar e in their chemical character, in so far as they are bases. ints of difference between the two series are of pretty much ne sense as those between the two prototypes. Thus, for e, while trimethylamine $N(CH_3)_3$ is a strong base, but inert gen gas, trimethylphosphine is a relatively feeble base, contact with air readily absorbs oxygen with formation of e $P(CH_3)_3O$, the like of which in the nitrogen series has no ce.

hur Compounds of Methyl.—Substances analogous to methyl- and methyl-ether respectively can be obtained by the dis- n of methyl sulphate of potassium with strong solutions of the potassium sulphides KHS and K_2S respectively. The $CH_3 \cdot SH$ is known as methyl-mercaptane, the other (CH sulphide of methyl. Both are very volatile stinking Sulphide of methyl claims a special interest as being the s point for the preparation of an important class of bodie trymethyl sulphine compounds. The sulphide $(CH_3)_2S$ unites with the iodide CH_3I into crystals of iodide of tri sulphine, $(CH_3)_3S \cdot I$, a substance which is closely analogou chemical character to the iodide of tetramethyl-ammonium. oxide of silver, for instance, converts it into a strongly basic h $S(CH_3)_3 \cdot OH$, which in its avidity for acids almost beats its a in the nitrogen family. An investigation of its salts was pu by Crum Brown and Blaikie.

Methyl Arsenides.—Arseniferous bases constituted like m di-methylamine (bodies such as AsH_2CH_3, analogous to NH do not seem to exist. What we do know of are—(1) a tri arsine and the iodide and the hydroxide of tetramethylars —$As(CH_3)_3$, $As(CH_3)_4I$, and $As(CH_3)_4OH$, bodies discove Cahours and Riche; (2) a whole series of monomethylic $As(CH_3)X_2$ (where X = Cl, Br, or X_2 = O,S), discovered by Ba 1857; (3) the kakodyle compounds, a series of bodies, $As(C$ or $As(CH \ldots X_2$, which were discovered and investigated by R. in 1842. The great investigation marks an epoch in the his organic chemistry, and our article would not be complete wit least a short summary of its result. Bunsen started in his inv tion with a liquid which had been obtained by Cadet as early a by the dry distillation of equal parts of white arsenic and ani acetate of potash, and which nobody cared to investigate fr it emits fumes which have an indescribably sickening smell intensity of poisonous action, compared with which that of arsenuretted hydrogen will appear insignificant. It was reserved for Bu attack this awful substance and force it to give an account o According to Bunsen, Cadet's liquid is substantially an $(AsC_2H_6)_2O$, which has strongly basic properties, readily ex its O for Cl_2, &c. To obtain the pure substance, the l distilled with corrosive sublimate and hydrochloric acid, w the first instance yields the pure muriate of the base $As(C$ in the form of a liquid volatile above 100° into vapours whi fire spontaneously in air. From this chloride of kakodyle t oxide is obtained by distillation with caustic potash. Th oxide emits no fumes, its specific gravity is 1·462; it boi 150°. A mixture of its vapour with air detonates at 50° C. the chloride again, Bunsen obtained the free radical *kak* $(AsC_2H_6)_2$ by treatment with metallic zinc in a special app so constructed that all the several operations involved co carried out without bringing the contents in contact with a necessary precaution, because kakodyle is a liquid which fire in air spontaneously even at ordinary temperatures. kakodyle is a heavy colourless liquid boiling at about 170° freezing at -6°. When exposed to oxygen or chlorine it destructive combustion; but on slow access of air it is oxidiz its oxide, $(AsC_2H_6)_2O$, and kakodylic acid; with chlorine it unites into the chloride which it came from; it also unites with sulphur and other elements, in short, it is exactly to dyle compounds what potassium is to potash and potash "a true organic element," as Bunsen himself put it. Th covery of Bunsen's was greeted with an enthusiasm whic difficult in these days to realize. With us now, a rad intrinsically as it was different in 1842. By the st of kakodyle the "radical" seemed suddenly rose from an un hypothesis to the rank of a theory based on experiment. however much our theoretical notions may shift, Bunsen's r will stand as a piece of monumental scientific work.

Kakodylic acid, $As_2O_3(CH_3)_2 \cdot OH$, is most conveniently pared from the oxide by addition of water and oxide of mer $H_2O + 2HgO$ supplying the $H_2 + O_3$ required for $1(AsC_2H_6)_2O$ is a crystalline monobasic acid, soluble in water. Unli kakodylides of the $As \ldots X_3$ type, it has no smell, and is violent poison. It takes six grains of it to kill a rabbit.

Metallic Methides.—Examples of these are—$Sb(CH_3)_3$; Sb $Mg(CH_3)_2$; $Zn(CH_3)_2$; $Pb(CH_3)_4$; $Al(CH_3)_3$; $Sn(CH_3)_4$. To idea of the chemical character of this interesting class of bo choose *zinc-methyl* as a representative example, and state the chief points of its chemical history. This body was discov Frankland in 1849. It is prepared by boiling iodide of meth granulated zinc in a flask connected with an inverted condens so contrived otherwise that the contents are protected agains of moisture and oxygen. Under these circumstances the i gredients gradually unite into a non-volatile and solid co $[Zn \cdot (CH_3)$. When this body is heated with more of io methyl, it undergoes decomposition, with formation of io zinc and of dimethyl gas, $I—Zn \quad CH_3 + CH_3I \quad ZnI_2 +$ which reaction to some extent takes place unavoidably in t paration of the zinc salt, however great an excess of metal taken. What survives needs only to be subjected to dry dist (in the absence of air) to yield a distillate of zinc-methyl:—

$$2I—Zn \cdot CH_3 = ZnI_2 + Zn(CH_3)_2.$$

methyl is a colourless liquid of 1·386 specific gravity at 10°·5, oils at 46° C ; in contact with air it takes fire. Water ses it at once into hydrate of oxide of zinc and marsh gas, $_2 + Zn(OH)_2 + 2CH_4H$. Of other reactions the following iamed. (1) When digested with sodium it yields a precipi- metallic zinc, and a double compound of itself and sodium- This latter unites readily with carbonic acid into acetate , $NaCH_3CO_2$ $CH_3 \cdot CO \cdot ONa$ (Wanklyn). (2) With of acetyl it forms acetone, $Zn(CH_3)_2 + 2CH_3 \cdot CO$, $Cl_2 = 2ZnCl_2(CH_3)_2$ (Frankland). (3) Under somewhat different condi- including the presence of an excess of $Zn(CH_3)_2$, a compound ed which with water, yields tertiary butyl-alcohol (Boutle-

$$A + 2H_2O = ZnO_2H_2 + CH_4 + 2(CH_3)_3 \cdot OH.$$
tertiary alcohol.

(W. D.)

TRONOME, an instrument for denoting the speed h a musical composition is to be performed. Its on is generally, but falsely, ascribed to Johann uk Maelzel, a native of Ratisbon (1772–1838). It of a pendulum swung on a pivot, below the pivot ved weight, and above it a sliding weight that the velocity of the oscillations by the greater or less from the pivot to which it is adjusted. The silent ome is impelled by the touch, and ceases to beat the impulse dies; it has a scale of numbers marked pendulum, and the upper part of the sliding weight ed under that number which is to indicate the of a stated note, as M.M. (Maelzel's Metronome) or ♩ = 72, or ♩. = 108, or the like. The number 60

a second of time for each single oscillation of the m,—numbers lower than this denoting slower, and numbers quicker beats. The scale at first ex- from 50 to 160, but now ranges from 40 to 208. complicated metronome is impelled by clock-work, a ticking sound at each beat, and continues its action works run down; a still more intricate machine a bell which is struck at the first of any number ts willed by the person who regulates it, and so the accent as well as the time.

earliest instrument of the kind, a weighted pendulum able length, is described in a paper by Etienne Loulié 1696; Amsterdam, 1698). Attempts were also y Enbrayg (1732) and Gabory (1771). Harrison, ned the prize awarded by the English Government chronometer, published a description of an instru- or the purpose in 1775. Davaux (1781), Pelletier, Buga (1790), and Weiske (also 1790) described arious experiments for measuring musical time. In Gottfried Weber, the composer, theorist, and essayist, ed a weighted ribbon graduated by inches or smaller , which might be held or otherwise fixed at any length, and would infallibly oscillate at the same as long as the impulse lasted: this, the simplest, is correct, the most enduring, the most portable, and apt invention that has come before the world, e can but wonder that it has not been universally ed. Stockel and Znaeckall produced each an instru- and Maelzel made some slight modification of that former, about the end of 1812, which he announced w invention of his own and exhibited from city to city Continent. It was, as nearly as can be ascertained, 2 that Winkel, a mechanician of Amsterdam, devised for reducing the movement length of all existing ments, on the principle of the double pendulum, rock- both sides of a centre and balanced by a fixed and a e weight. He spent three years in completing it, is described and commended in the *Report of the Lands Academy of Sciences*, August 14, 1815. Maelzel oon went to Amsterdam, saw Winkel and inspected ention, and, recognizing its great superiority to what ed his own, offered to buy all right and title to it. Winkel refused, and so Maelzel constructed a copy instrument, to which he added nothing but the s numbers, took this copy to Paris, obtained a patent and in 1816 established there, in his own name, a factory for metronomes. When the impostor re Amsterdam, the inventor instituted proceedings him for his piracy, and the Academy of Sciences d in Winkel's favour, declaring that the graduated sca the only point in which the instrument of Maelzel d from his. Maelzel's scale was needlessly and arbi complicated, proceeding by twos from 40 to 60, by from 60 to 72, by fours from 72 to 120, by sixes fro to 144, and by eights from 144 to 208. Dr Crote structed a time measurer, and Henry Stuart (the vi and father of the composer of the same name) made a in 1821, both before that received as Maelzel's was in England. In 1882 James Mitchell, a Scotsman an ingenious amplification of the Maelzel clock reducing to mechanical demonstration what formerly wholly on the feeling of the performer. Al "Maelzel's metronome" has universal acceptance, th metronome and still more Weber's graduated ribb greatly to be preferred, for the clock-work of the liable to be out of order, and needs a nicety of reg which is almost impossible; for instance, when Sir Smart had to mark the traditional times of the pieces in the Dettingen Te Deum, he tested them by metronomes, no two of which beat together. The v the machine is exaggerated, for no living performe execute a piece in unvaried time throughout, student could practise under the tyranny of its bea conductors of music, nay, composers themselves, w the same piece slightly slower or quicker on d occasions, according to the circumstances of perform

METSU, GABRIEL, a Dutch painter of celebrity in 1630, died after 1667), is one of the few ar renown in Holland whose life has remained Houbraken, who eagerly collected anecdotes of in the 18th century, was unable to gather more fr gossip of his contemporaries than that, as early as Metsu, at the age of forty-three, submitted to a da surgical operation. The inference drawn by su readers from this statement has been that death imm ensued. A more careful perusal would have sho Houbraken knew that Metsu had given lessons Musscher in 1665. Local records now reveal that was the son of Jacques Metsu, who lived most of h at Leyden, where he was three times married. The these marriages was celebrated in 1625, and Ja Garnijers, herself the widow of a painter, gave Gabriel in 1630. Connected by both his parents w Metsu was probably taught first by his father and Gerard Dow. He probably finished his training Rembrandt. So far back as 1648, but a few days than Jan Steen, who is said to have painted his Metsu was registered in the painters' corporation at and the books of the guild also tell us that he rem member in 1649. In 1650 he ceased to subscribe, an bearing his name and the date of 1653 give counten the ef that he had then settled at Amsterdam, w continued his studies under Rembrandt. His com at the time would naturally be De Hooch and Meer, whose example he soon followed when it cam turn to select the class of subjects for which his fitted him. Under the influence of Rembrandt duced the Woman Taken in Adultery, a large pictu the date of 1653, in the Louvre, in which no on suspect the painter of high life or taverns were it his name is written at full length on the canva artist who thus repeated the gospel subjects fam

and Eeckhout was also acquainted with the Oriental
be of Rembrandt, and ready to use it, like all his
poraries. But he probably observed that sacred
s ill suited to his temper, or he found the field
ongly occupied, and happily for himself, as well
his admirers, he turned to other subjects for
ne was better fitted. We may doubt whether he
he style of allegory as illustrated in a picture of
Protecting Virtue and Chastising Vice in the
of the Hague. There is every reason to think that
ugh and frosty composition was wrought by quite
master. What Metsu undertook and carried out
he first with surprising success was the low life of
rket and tavern, contrasted with wonderful versa
y incidents of high life and the drawing room.
of these spheres he combined humour with expres-
keen appreciation of nature with feeling, and breadth
elicacy of touch, unsurpassed by any of his contem-
s. In no single instance do the artistic lessons of
andt appear to have been lost upon him. The same
les of light and shade which had marked his school-
the Woman Taken in Adultery were applied to
s of quite a different kind. A group in a drawing-
series of groups in the market place, a single figure
gloom of a tavern or parlour, was treated with the
felicity by fit concentration and gradation of
a warm flush of tone pervaded every part, and, with
ne study of texture in stuffs was carried as far as it
en by Terburg or Dow, if not with the finish or
o of De Hooch. Metsu's pictures are all in such
ble keeping, and so warm and harmonious in his
or so cool and harmonious in his closing time,
ey always make a pleasing impression. They are
ubtle in modulation than Dow's, more spirited and
in touch than Terburg's; and, if Terburg may of
laim to have first painted the true satin robe, he
ainted it more softly or with more judgment as to
than Metsu.

Metsu married and became a citizen of Amsterdam
would only prove that his residence in the com-
capital of the Netherlands was later than historians
enerally assumed. But there is no reason to think
etsu claimed his citizenship at once. The privileges
rgess were given in exchange for a payment of dues,
ese painters had various ways of avoiding unless they
d. One of the best pictures of Metsu's manhood is
rket-place of Amsterdam, at the Louvre, respecting
it is difficult to distribute praise in fair proportions,
llent are the various parts, the characteristic move-
nd action of the *dramatis personæ*, the selection of
he expression and the gesture, and the texture of
ngs depicted. A tin can in the arm of a cook is a
of imitation, but the cook's face is also a marvel
ression. Equally fine, though earlier, are the
nan (dated 1661) and the Tavern (also 1661) at the
and Dresden Museums, and the Game-Dealer's Shop,
Dresden, with the painter's signature and 1662.

is one of the painters of whose skill Holland still pre-
xamples, yet whose best pictures are either in England or in
or in the galleries of Germany. The value of his works is
d at the Pommersfelden sale in 1867 the Jealous Husband
g his Wife's Letters, though but one of several replicas,
ght by Lord Hertford for little short of £2000, while for
e of the Prince of Orange, in the Gsell collection at Vienna,
was paid by Baron Rothschild in 1873. (J. A. C.)

TTERNICH, Clemens Wenzeslaus, Prince (1773–
first minister of Austria from 1809 to 1848, was
n of a Rhenish nobleman employed in high office by
ustrian court. He was born at Coblentz in 1773.
age of fifteen he entered the university of Strasburg.
rench Revolution was then beginning. Everywhere
the spirit of hope gave to men's language an exaltati
a confidence hardly known at any other epoch. B
darker reality soon came into view. Metternich
witness of the riot in which the town-hall of Strasbu
pillaged by a drunken mob; his tutor subsequently
a member of the revolutionary tribunal in Alsace.
are to trust to Metternich's own account of the for
of his opinions, the hatred of innovation, which
ruling principle of his later life, arose from his exp
of the terrible results which followed at this time fr
victory of so-called liberal ideas. But in reality Met
was an aristocrat and a conservative by birth and
His sentiment in things political was that of a men
a refined and exclusive society which trusts to no
gence but its own, and hardly sympathizes with
interests. The aggressions and violence of the Revo
from 1789 to 1799 gave Metternich an historical ba
his political theories, but the instinctive preferences
own mind were the same from first to last. He beg
as a young man of fashion and gallantry. His m
in 1795 with the Princess Kaunitz, a granddaughter
famous minister, fixed him in the highest circle of A
nobility. His first contact with the great political
was at the congress of Rastadt in 1798, where, und
auspices of the victorious French republic, arrange
were made for compensating the German princes and
whose possessions on the left bank of the Rhine had
ceded to France by the peace of Campo Formio. Met
was the accredited agent of a group of Westphalian
his private letters give a vivid picture of the roug
uncouth diplomatists who had succeeded to the p
servants of the old French monarchy. In 1801 Met
was appointed Austrian ambassador at Dresden,
1803 he was promoted to Berlin; but he had
become as yet a prominent man in Europe. His
Berlin was the turning point of his life. The war
third coalition was impending. Austria united with E
and Russia against Napoleon, and the task of the y
ambassador was to win over the court of Berlin
cause of the allies. Metternich seems to have d
that it was possible for him to do; but Prussia p
in its neutrality. The earnestness with which Met
had worked against France did not prevent him
remaining on the friendliest terms with M. Lafo
French ambassador at Berlin; and so agreeable an a
of him was transmitted to Paris by his rival that,
close of the conflict, Napoleon himself requeste
Metternich might henceforward represent Austria
Tuileries. Metternich was accordingly sent to P
1806. This was the beginning of the period when A
humbled but not exhausted by the blow of Austerl
by the losses accompanying the peace of Pressburg
mined, under the leadership of Count Stadion, to
for another war on a greater scale. But the sudde
throw of Prussia, and the alliance between Fran
Russia which was made at Tilsit in 1807, added imm
ably to the difficulties of the court of Vienna. It
clear that Napoleon was intending to dismember
and to gain for himself some part of the spoils of th
man empire. Metternich's advice was that Austria
endeavour to detach the czar from the French allian
by this means frustrate the plan of partition, but,
Russia held fast to Napoleon, that Austria itself shoul
with the two aggressors, and secure its share of
Oriental affairs, however, fell into the backgroun
in the summer of 1808 Metternich was convinc
Napoleon was intending to attack Austria, though
mediately. He warmly supported Count Stadion's
in raising the forces of Austria to the highest st
and, although he did not share the minister's hop

rising throughout Germany, he expressed in his
hes no distrust of the power of Austria to cope
Napoleon. This is the more singular because,
he disastrous issue of the campaign of 1809,
nich seems to have taken credit for having
l the policy of war. Napoleon again captured
; the battle of Wagram was lost; and after a long
tion Austria had to purcha e peace by the cession
of Austrian Poland and of its Illyrian provinces.
nich, who had virtually taken Count Stadion's place
ately after the battle of Wagram, was now installed
ter of foreign affair . The first striking event
ok place under hi administration wa the marriage
e Louise, daughter of the emperor Francis, to his
ror Napoleon. To do justice to Metternich's policy
be remembered that the alliance of Tilsit between
and Ru ia was still in existence, and that Austria
te as much threatened by the czar's designs upon
as by Napoleon's own aggressions. Metternich
seems, in spite of his denials, to have been the real
of the family union between the house of Hapsburg
onaparte, a most politic, if not a high-spirited
, which guaranteed Austria against danger from
t, at the same time that it gave it at least some
t of security from attack by Napoleon, and enabled
nich to mature his plan for the contingency of an
e breach between France and Russia. In 1812 this
occurred. Metternich, in nominal alliance with Napo-
nt a small army into southern Russia, allowing it to
erstood by the czar that the attack was not serious,
ollowed the annihilation of the French invaders.
Prussia, led by its patriots, declared war against
on, Metternich, with rare and provoking coolness,
s hand, merely stating that Austria would no longer
itself as a subordinate ally, but would act with all its
one side or the other. The result of this reserve
t Metternich could impose what terms he pleased on
and Prussia as the price of his support. The armies
se two powers, advancing into central Germany,
no match for the forces with which Napoleon took
l in the spring of 1813; and the hard fought battles
zen and Bautzen resulted in the retreat of the allies.
the combatants had made an armistice, Met-
tendered Austria's armed mediation, requiring
to content itself with the restoration of its territory
the Elbe, and leaving Napoleon a tendency in
y almost untouched. Napoleon, after a celebrated
w with Metternich, madly rejected terms
t every Prussian writer has denounced Metternich's
l of them as an act of bitter enmity to Prussia.
night of the 10th of August the congress of Prague, at
Austria, as armed mediator, laid down conditions of
was dissolved. Metternich himself gave order for
ghting of the watch fires which signalled to the
in Silesia that Austria had declared war against
on. The battle of Leipsic and the campaign of
n France followed, Metternich steadily pursuing the
of offering the most favourable terms possible to
on, and retarding the advance of the allied armies
he French capital. Metternich had nothing of that
l hatred towards the great conqueror which was
ant both in Prussia and in England; on the contrary,
he saw with perfect clearness that, until Napoleon's
es were much diminished, no one could be safe in
, he held it possible to keep him in check without
ing him, and looked for the security of Austria in
ablishment of a balance of power in which neither
nor France should preponderate, while Prussia
be strictly confined within its own limits in northern
ny. The assistance of the Austrian army, which
was no doubt necessary to the allies, had, so far as re
to Prussia, been dearly purchased. When, at the begin
of 1813, Prussia struck for the freedom of German
leading statesmen and patriots had hoped that the r
of the war of liberation would be the establishmen
German unity, and that the minor German princes,
had been Napoleon's vassals since 1806, would be force
surrender part of their rights as sovereigns, and subm
a central authority. This dream, however, vanishe

Austria entered the field as an ally. It wa
part of Metternich's policy to allow anything so re
tionary as German unity to be established, least o
under the influence of Prussian innovators. He
treaties with the king of Bavaria and Napoleon's
German vassals, guaranteeing them, in return for
support against France, separate independence and
reignty when Germany should be reconstructed. Ac
ingly, though the war resulted, through Napol
obstinate refusal of the terms successively offered to
in the limitation of France to its earlier boundaries and
large extension of Prussia's territory, the settlemen
Germany outside Prussia proceeded upon the lines
down by Metternich, and the hopes of unity raise
1813 were disappointed. A German confederation
formed, in which the minor sovereigns retained sup
power within their own states, while the central autho
the federal diet, represented, not the German nation
the host of governments under which the nation
divided. Metternich even advised the emperor Franc
Austria to decline the old title of German emperor
liking any open embodiment of the idea of German u
and preferring to maintain the ascendency of Austri
a gentle pressure at the minor courts rather than by
avowed exercise of imperial rights. In this unprogre
German policy Metternich was completely succes
His great opponent, Stein, the champion of German
and of constitutional systems, abandoned his wor
despair, and refused the useless post of president o
diet, which Metternich, with a kind of gentle irony, of
to him.

The second branch of Metternich's policy in 181
was that which related to Italy. Following the old ma
of Austrian statesmanship, Metternich aimed not on
securing a large territory beyond the Alps but at ma
the influence of Austria, predominant throughout the It
peninsula. The promises of national independence w
had been made to the Italians when they were called
to rise against Napoleon were disregarded. In the s
clauses of the first treaty of Paris the annexation of
Lombardy and Venetia was guaranteed to Austria, an
rest of Italy was divided into small states as of
Napoleon's return from Elba led to the downfall of M
who had been allowed to retain the kingdom of Naples
to the reunion of this country with Sicily, under the Bou
Ferdinand. After the second overthrow of Napo
Metternich endeavoured to make every Italian sove
enter into a league under Austria's presidency. Ferdi
of Naples accepted the position of vassal, but the pope
the king of Sardinia successfully maintained their
pendence. With the construction of the German federa
and the partial construction of an Italian federation,
under Austria's guidance, the first part of Metter
career closes. He had guarded Austria's interests
great skill during the crisis of 1813 and 1814. It wa
his own fault, but the fault of ages, that Austria's int
were in antagonism to those of German and of It
nationality. He thought as an Austrian, and as no
else; his task was to serve the house of Hapsburg, an
he did with signal ability and success. To denc
Metternich as a kind of criminal, according to the pr

sian writers, because he did not work for German
s to ignore the existence of such a thing as state
Judged by the ordinary standards of practical
and dips, not by the philosophy of history,
rich's action in 1813 and 1814 was that of a very
r man, and the qualities of calmness and dexterity
he displayed would have given an infinitely greater

ment not surpassed in the annals of political
When Napoleon fell, there was a prospect of the
tion of constitutional government throughout a
art of Europe. King Frederick William, stimulat
effort of the Prussian people against France by the
of liberty, had definitely promised the establishment
al a general assembly. The czar had determined to
e parliamentary life into the kingdom of Poland,
n hoped to extend it, after some interval, to Russia.
deral Act drawn up for Germany at the congress of
declared that in every state within the German
a constitution should be established. Against this
movement of the age Metternich resolutely set his
Though wide general causes were at work, the
influence of the Austrian statesman had no small
in prolonging the existence of autocratic government,
developing that antagonism between the peoples
eir rulers which culminated in the revolutions of
The nature of the Austrian state, composed of so
heterogeneous provinces and nationalities, no doubt
natural for its representative to defend and exalt
ciple of personal sovereignty, on which alone the
f Austria was based; the relation of Austria to Italy
d the growth of the sentiment of nationality a real
of danger to the house of Hapsburg; but Metternich's
ence of constitutional and popular ideas was more
e outcome of a calculating policy. He was not a
much faith, but one belief he held with all the force
tious conviction,—namely, the belief that his own
d mission in the world was to uphold established
ty. All efforts to alter the form or to broaden the
f government he classed under the same head, as
of the spirit of revolution; and in one of his most
writings he places side by side, as instances of evil
for its own sake, the action of the secret societies
many, the Carbonaria of Italy, and the attempt of
glish to carry the Reform Bill. Working on prin
like these, and without the shadow of a doubt on
wisdom, Metternich naturally proved a great power
me when the sovereigns who had inclined to constitu
ideas began to feel the difficulties in the way of
them into practice. Metternich's advice, tendered
very grace of manner and with the most winning
suasive art, was indeed not hard for rulers to accept,
simply recommended them to give up nothing that
d got. It was at the congress of Aix-la-Chapelle
that the retrograde tendency, which was now suc-
ceeding to the hopes of 1815, first gained expression
agitation among the students at the German univer
caused some scandal in the previous year, and secret
had just been discovered in Russia. Metternich pl
king of Prussia with argument for withholding the

A few months later the murder of Alexander
agent, Kotzebue, by a fanatical student gave Metter
excellent pretext for organizing a crusade against
liberty. A conference of ministers was held at Ca
The king of Prussia allowed his representative to
Metternich's lead. The resistance of the constit
minor states proved of no avail; and a series of reac
was passed which made an end of the freedom of th
throughout Germany, and subjected the teaching
discipline of the universities to officers of state. A c
tion was established at Mainz to investigate the consp
which Metternich alleged to have been formed for th
throw of all existing government, and for the creati
German republic, one and indivisible. To the followi
new articles were added by Metternich's direction
Federal Act, the most important being on
forbade the creation in any German state of an a
representative the community at large, and enjoi
system of representation by separate estates or order
possessed of certain limited definite rights, and al
subordinate to the supremacy of the crown. Met
would gladly have made an end of the parliamenta
stitution, which had already come into being in Bava
the southern states; but he was unable to attac
openly, and had to confine himself to the advo
strict monarchical principle through his representat
these courts. With regard to Prussia, however,
completely successful. The king of Prussia bro
promise of establishing a national representatio
satisfied his conscience by creating certain powerl
provincial diets, exactly as Metternich had recommende
Throughout Germany at large a system of repres
carried out against the advocates of constitutiona
The press was silenced; societies were dissolved
tions became more and more common. While Met
imagined himself to be stifling the spirit of dissent
was in fact driving it into more secret and more
courses, and convincing eager men that the regen
of Germany must be sought not in the reform but
overthrow of government.

Meanwhile revolution broke out in Spain and
Ferdinand of Spain, who had restored despotism, w
pelled, in March 1820, to accept the constitution
which he had subverted. The same constitutio
accepted a few months later by Ferdinand of
Spain was outside Metternich's range, but his ha
heavily upon Naples. A congress of the great pow
held at Troppau in October 1820. Metternich, w
president, as he had been at Vienna, and continued t
later congresses, completely won over the czar to h
views. Resolutions in favour of an intervention, i
case by force of arms, against the Neapolitan liberal
movement were adopted by Austria, Russia, and Prussia,
England and France held aloof. The congress w
adjourned to Laibach in Carniola, whither Ferdin
Naples was summoned, in order that he might
between the powers and his people, and induce th
to give up a constitution which offended the three m
courts. Ferdinand's journey and mediation were a
ture as regarded the Neapolitans, he pretended
went to negotiate on behalf of his people, when in
intention was exactly the same as Metternich's, nam

bsolute monarchy restored. The proceedings of
ngress at Laibach were a farce. A letter was
ed by Metternich for King Ferdinand to send to
jects, informing them that the powers would not
the constitution to exist, and that, in default of
ubmission the allied courts would employ force.
ish Government, while protesting against the joint
of the three powers as an assumption of international
entry, was perfectly willing that Austria, as a state
ened by the Neapolitan revolution, should act on
account. Metternich however, continued to treat
eapolitan question as the affair of Europe, and
ined his concert with Russia and Prussia. Early
l an Austrian force came in the name of the allies,
l central Italy. The armies opposed to it col
and the Austrians entered Naples on March 24.
the meantime a revolution broke out in Pied
which threatened to cut off the Austrians from
upport, and to raise all Italy against them. For a
t the bold action of Metternich seemed to have
l in immense danger both to his own conservative
and to the peace of Europe, for it was believed that
dmont's revolution would be answered, not only
eneral Italian movement, but by a rising against
rbons in France. The cloud, however, passed away.
was quickly restored in Piedmont; Lombardy was
eld by Austrian garrisons; and the conclusion of
lian difficulties in which Metternich had played a
fficult part with great resolution and dexterity, was
plete and brilliant personal triumph. No statesman
ope at this moment held a position that could com
th his own.

he congress of Verona, held in 1822, the affairs of
were considered by the powers. In the end, the
constitution was overthrown by a French invading
but, though the army employed was that of France
nciple of absolutism which animated the crusade
at which Metternich had made his own. A severe
however, now met him in another quarter. Greece
n against Turkish rule in 1821. The movement
entually a national and a religious one, but Metternich
it as a Jacobinical revolt against lawful authority,
ring, or affecting to confuse, the struggle for national
dence with the shallow and abortive efforts of politi-
alism in Italy and Spain. Metternich's attitude
the Greeks was for some time one of unqualified
y. If, under the pressure of the Tilsit alliance, he
been willing that Austria should join Russia in
ding Turkey, he had now reverted to the principle
intaining Turkey at all costs against a Russian
southward, and he attributed the Greek move-
to the efforts of Russian agitators unauthorized by
r. His desire was that the sultan should deprive
of all possible cause for complaint as regarded its
eparate interest, and so gain freedom to deal sum-
with the Greek. Metternich's hopes failed, partly
h the obstinacy of the Turks, partly through the
ng conduct of Alexander, and partly through the
of Castlereagh and the accession of Canning to
It was in great part owing to Canning's moral
t that Greece ultimately became an independent
and the extraordinary violence of Metternich's
ge whenever he mentions this English statesman
only too well the impotent character of his aims.
ulteran has left a more damning record against
f than Metternich in his bigoted abuse of Canning.
rock question, however, was only the first on which
dgment of events was now beginning to declare itself
Metternich and all his principles. The French
tion of 1830 shattered the moral fabric which he had so proudly inaugurated, and in great part
raised, in 1815. The accord that grew up be
England and France now made any revival
kind of presidency that he had once held in
impossible. He was indeed bold and rapid in
my troops into the papal territory when revolut
movements broke out there in 1831 and 1832, thoug
with France seemed likely to result from this step
was as unsparing as he had been in 1819 in suppress
agitation which after 1830 spread from France to Ger
and the union of the three eastern courts was one
exhibited in the meeting of the monarchs which took
at Munchengratz in 1833, and in a declaration delive
Paris, insisting on their right of intervention
revolution in other countries. It was, however, th
czar of Russia, Nicholas, who was now the real h
European conservatism; and the stubborn charact
narrow, unimaginative mind, of this prince m
impossible for Metternich to shape his purposes
delicate touch which had been so effective with h
decessor. But in Austria itself Metternich co
without a rival. In 1835 the emperor Francis
whom he had worked for nearly thirty years,
Metternich, himself falling into the mental habits
age, remained at the head of the state. 1848
revolution of that year ended his political caree
resigned office with the dignity of demeanour whi
never failed him; his life was scarcely safe in Vien
the old man came for a while to England, which
not visited since 1794. Living on till June 1859,
every great figure of his earlier life, and many that
peared on the horizon since his own prime, pass awa
a few more months of life would have enabled him
the end of that political order which it had been
work to uphold, for the army of Napoleon III. was c
the Sardinian frontier at the moment when he die

'URTHE ET MOSELLE, a department in the north-
France, formed in 1871 out of those parts of the old departments of Meurthe and Moselle which con
French, and deriving its name from the two principa
which water it. Prior to 1790 it belonged to
Lorraine, or to one or other of the bishoprics of Tou
and Verdun. It lies between 5° 25′ and 7° 5′ E
and 48° 25′ and 49° 5′ N. lat., and is bounded on
by Alsace-Lorraine, on the N. by Belgium and the
duchy of Luxemburg, on the W. by the departm
Meuse, and on the S. by that of Vosges. The sup
area is 2030 square miles. Geologically Meu
Moselle has five well-marked regions, following each o
regular succession from east to north-west. On the f
of Alsace are the Vosges mountains, of Trias an
(*grès Vosgien*), with a maximum elevation of 300
A narrow band of variegated sandstone divides the
from the second region, formed of shelly limestone,
extends as far as the Meurthe on the north and the
on the west. The third region is formed by the var
marls which cover the rich-saline strata of the neig
hood of Nancy. The Jura limestones of the L
Oolite, to the north-west and west of the departmen
the last two regions. Here there is a maximum el
of 1400 feet, and the plateau of Briey stretches out t
that of the Ardenne. Between the Vosges a

The principal salt working centres (St Nicolas, ville, and Rosières aux Salines) lie between Nancy and e ; the annual value of rock salt and refined salt produced 4,500,000 , subsidiary to the production i an important ture of soda salts The other chemical product are of potash, bone black wax candles , soap and marble marrying and the manufacture of plaster and lime are also t branche of industry The flint glass manufactory at , which employs nearly 1500 workmen i well known, plate glass at Cirey with 1000 workmen produce plate sizes The faience manufactories of Lunéville, Toul, and are important Mention may also be made of the ture of window-glass, watch glasses, and drinking bo e acco manufacture at Nancy employ 1000 workmen tan ove making, hat making in felt and straw, wool printing, manufacture of army clothing are also carried on Nancy ined for it embroidery, which i however unimportance It also possesses factories for cotton printed on stuffs, but for hosiery The lace manufactories and ories , especially that of Tantonville, the largest in France, ploy protective Nancy also carries on distilleries, granulated sugar, manufacture of pasteboard objects and a large establishment The commerce of the department is facilitated by 700 miles of railway (the principal line being that from Strasbourg through Nancy , by a number of good roads, several navigable rivers and canals The most important waterway is that by the canal between the Marne and the Rhine, which Toul and Nancy, and traverses the department from west to The canal communicates with the Moselle, which enters the department from Frouard downwards, and with the new eastern canal, which unites the Moselle to Saint Epvre, and which is intended to connect the Marne and the Moselle with the Saône and the Rhone. The population of Meurthe et Moselle on 1st January 1891 was 419,674 souls It comprises the diocese of Nancy in the court of appeal of Nancy and forms a part of the district of the 6th army corps (Châlons sur Marne) There are 4 arrondissements (Nancy, Lunéville, and Toul , 29 cantons and 594 communes The chief towns are Nancy (the capital of the department, the seat of a university, of a prefect, and of a fortified place, population 68,130) and Pont à Mousson, celebrated for its glass wool

MEUSE, Maese, or Maas, a river of France, Belgium, Holland, discharging into the North Sea or German Ocean, has a course (variously measured) of some 500 or 600 miles, about 300 miles lying within France Rising in the department of Haute Marne (1345 feet), at a point on the plateau of Langres bordering on the Monts Faucilles, it follows a winding course, first from south to north, then north-west, and afterwards to north, across the department of Vosges, Meuse, and Ardennes, passing by Neufchâteau, Vaucouleurs, Commercy, St Mihiel, Verdun, Stenay, Mézières, and Givet Naturally navigable below Namur, it has been made so from Troussey, where it meets the canal which unites the Marne to the Rhine, and from Namur to Liege it admits vessels of from 6 to 7 feet draught. After traversing a wide valley covered by green meadows, the Meuse, below Mézières, flows through narrow gorges confined between rocky walls 200 or 300 feet high, bordered by the plateau of the Ardennes The hills of the Ardennes, by which it is hemmed in on its upper course, and its receiving any important affluent before the Sambre and the Semoy, which both fall into it on the right from the Ardennes. At the point where it leaves France its mean volume is about 1000 cubic feet. In this part of its course it flows picturesquely between the districts of Famenne and Condroz on the right, and those of Les Fagnes and Hesbaye on the left. Above Dinant it receives the Lesse, whose valley is celebrated for its wonderful grottoes, and at the foot of the citadel of Namur it is joined on the left by its principal affluent, the Sambre, whose north-easterly direction for 60 miles. It then takes its course through the hilly valley in which Huy, Seraing, and Liege are situated, receiving further on its right the Ourthe. Resuming a northerly direction, after making one to the north-west, and finally one to the west, the Meuse passes in front of the Dutch city of Maestricht to Roermonde, so called from it connection there with the Roer, and to Venlo, where the canal between the Meuse and the Scheldt begins Flowing thence through an absolutely unbroken plain, it finally joins the Rhine which it gives it own name, although the volume of water is twenty times less than that of the German It is at Gorcum that the Waal, the first separate branch of the Rhine, brings to the Meuse two-thirds of the volume of that river The Meuse soon after divides into two branches While the Merwede flows due west, the Old Meuse arm falls into the Biesbosch, an estuary of the sea, formed two hundred and fifty years ago by an irruption of the sea over a country then cultivated and thickly peopled, and now the object of attempts at reclamation. On reaching Dordrecht, where the river navigation and canal traffic meet, and where the raft which come down from the Black Forest are broken up, the Meuse again divides into two arms The Old Meuse flow due west while the northern arm joins the Lek, a second branch of the Rhine, and continues its course to Rotterdam. This is the important branch of the estuary of the Meuse and Rhine are being made to regulate and deepen it channel by constructing new canals in which the locks are so skilful Schiedam and Vlardingen, both on the right, are the first places of importance on the banks of the river.

MEUSE, a department in the north-east of France, formed out of a part of Lorraine and portions of the Three Bishoprics, the Clermontais, and Champagne, derives its name from the river by which it is traversed from south to north. It lies between 4° 56' and 5° 50' E long and between 48° 26' and 49° 38' N lat, and is bounded on the N by Belgium and the department of Ardennes, on the E by that of Meurthe et Moselle, on the S by those of Vosges and Haute Marne, and on the W by those of Marne and Ardennes. Of its superficial area, (1,247 square miles), about one half belongs to the basin of the Meuse, which is enclosed to the east and west by the eastern and western Argonnes. On the north-east it is watered by the Orne, a tributary of the Moselle, by the Chiers, which runs by Montmedy, and joins the Meuse a little beyond the northern limit of the department, and by other half and its waters to the Seine through the Aisne, a tributary of the Aisne, both of which take their rise in and by the Ornain, an affluent of the Saône, the latter being tributary to the Marne The Meuse, the most important river in its course through the department, has its highest elevation (1358 feet) to the south where the line of the ridge which separates the basin of the Meuse from that of the Seine The height gradually from south to north, but seldom falls below 1000 feet. The hill of the western Argonne similarly sink rapidly in the valley of the Aire, where the lowest level of the department (377 feet) is reached The climate of the is transitional between the region of the Seine and that of the Vosges, it winters are less severe than those of the latter but it is not so temperate as the former The mean annual temperature is 52° Fahr. As at Paris, the mean cold is 9° Fahr; the greatest heat rarely exceeds 90° Fahr.

More than half the surface of the department consists of arable lands, one fourth of forest, one tenth of meadow The proportion of horses is larger than in any other French department except La Manche There are 53 800 horses, 99,000 cattle, 115,000 sheep, 125,000 pigs, and nearly 30,000 bees The potatoes, and beet-root are the chief crops, and 1 77 to 966 of wheat, 101,660 quarters of barley, 58 650 quarters of 7 677,374 bushels of potatoes, beside peas, hemp, and flax vineyards produced more than 6,600,000 gallons of wine quality. The forests which are principally of oak, nourish game, as are the rivers in fish. The mineral wealth of the

ludes iron ore, good free stone, and fossil phosphates of lime. ; blast-furnaces, iron, copper, and bell foundries, wire- nd manufactories of tiles, hardware, and edge tools. The rming factories employ 15,000 spindles and 12,000 frames ben manufacture employs 5000 people and one hundreds re also employed in the spinning and weaving of hemp, flax, . The glass works, particularly the manufactory of painted ss, transferred after the war of 1870 from Metz to Bar- ; paper mills, saw-mills, and flour mills as well as the ture of straw, tiles, and woollen cloth are worthy of mention and embroidery is also carried on for a great number of ps. and the department has long been celebrated for its confectionery ontains more than 300 miles of railways, the principal lines at from Paris to Strasburg through Bar-le-Duc and Com- mercy, that from Paris to Metz through Verdun, and the line to the Meuse. The chief waterways are the canal com the Marne with the Rhine, and the canal of the Meuse; t together have a length of 146 miles. The population of the ment in 1881 was 289,861, a small number in proport its extent, and with a tendency to decrease. Ecclesiastic form the diocese of Verdun, it has its court of appeal at and constitute part of the district of the army corps of C sur-Marne. There are 4 arrondissements, Bar-le-Duc, Com Montmedy, and Verdun,—28 cantons, and 586 communes. le-Duc (population in 1881, 17,185) is the capital, Co has 5260 inhabitants and Montmedy 3000. St Mihiel (59 the Meuse, has good churches and some remarkable rocks, the seat of the departmental assize court.

MEXICO

I. ANCIENT MEXICO

The name Mexico is connected with the name of the people of Anahuac (q.v.) tribes calling themselves *Mexica* (*Mexi'ca*, or *Aztec*. The word is related to or to one the name of the Mexican national war god (better known as Huitzilopochtli). The Aztec from the 12th century appear to have migrated from place to ver the mountain-walled plateau of *Anahuac*, the ey, the water-encircled from its salt lagoons, and now known as the valley of Mexico. About 1325 anded on the lake of Texcoco the permanent settle- f Mexico Tenochtitlan, which is still represented by ital city Mexico. The name Mexico was given by panish conquerors to the group of countries over the Aztec power more or less prevailed at the time European invasion. Clavigero (*Storia Antica del* ., vol. i.) gives a map of the so-called "Mexican which may be roughly described as reaching from ent Zacatecas to beyond Guatemala. It is noted at both these names are of Mexican origin, derived ively from words for "straw" and "wood." Eventu- exico and New Mexico came to designate the still ions of Spanish North America, which (till cut by changes which have limited the modern republic ico) reached as far as the Isthmus of Panama on th and took in California and Texas on the north. in this wide sense it is of high interest to the ological, from the several native American civiliza- which appear within its limits, and which con- ly it loosely group themselves round two centres, xican proper and the Central American.

n early in the 16th century the Spaniards found ly from the West Indian Islands to this part of the nent of America, they came in view of nations cultured ove the level they had hitherto met with in the New Here were not rude and simple tribes like the s of the Antilles, but nations with organized armies, administrators, courts of justice, high agriculture chanical art; and, what struck the white men ally, temple-buildings whose architecture and sculpture ften of dimensions and elaborateness to astonish the rs and sculptors of Europe. How a population of s could inhabit a world whose very existence had ill then unknown to geographers and historians, and s nations could have reached so high a grade of ic industry and grandeur, was a problem which lly excited the liveliest curiosity of scholars, and gave a whole literature. Humboldt and Acosta shared inion of their time that the great fossil bones found xico were remains of giants, and it was argued that, re the deluge there were giants on the earth, there Mexico was peopled from the Old World in ante n times. On the other hand the multitude of American languages suggested that the migration rica took place after the building of the tower of Babel, and Sigüenza arrived at the curiously definite that the Mexicans were descended from Naphtuhim, Mizraim and grandson of Noah, who left Egypt for shortly after the confusion of tongues. Although speculations have fallen out of date, it is to be remem in their favour that they were stepping stones to mor argument; especially they induced the collection of traditions and invaluable records of races, language customs, which otherwise would have been lost for Even in the present century Lord Kingsborough w to spend a fortune in printing a magnificent compila Mexican picture writings and documents in his *Anti of Mexico* by his zeal to prove the theory advoca Garcia a century earlier, that the Mexicans were t tribes of Israel.

Real information as to the nations of Mexico Spanish times is very imperfect, but not altogether ing. It is derived partly from inspection of the themselves, their languages and customs, which n now briefly considered, before going on to the recoll handed down in the native picture-writings and ora tions. The remarks made by the accurate and expe observer Alexander von Humboldt, who had seen American tribes than almost any traveller, are still to the greatest weight. He considered the Americans of both continents to be substantially n race characters. Such a generalization will consider it, as is now generally done by anth gists, the Eskimo with their pyramidal skull complexion, and flat noses are removed into a by themselves. Apart from these polar nomad American indigenes group roughly into a sing or division of mankind, of course with local var If our attention is turned to the natives of Mexico ally, the unity of type will be found particularly The native population of the plateau of Mexico, Aztecs, may still be seen by thousands without any mixture of European blood, and the following desc may give a fair idea of them appearance.[1] Their st somewhat low, estimated about 5 feet 3 inches, bu are of muscular and sturdy build. Measurements skulls show them mesocephalic (index about 78), o mediate between the dolichocephalic and brachyc (narrow and wide skulled) types of mankind. The oval, with low forehead, high cheek bones, lon sloping outward towards the temples, fleshy lips, no and in some cases flattish but in others aquiline, moulded features, with a somewhat stolid and expression. Thickness of skin, masking the muse been thought the cause of a peculiar heaviness in t lines of body and face; the complexion varies from brown to chocolate (about 40 to 13 in the anthrop

[1] References may be found in Bancroft, *Native Races of th States*, vol. i. pp. 21, 573, 618, 646.

eyes black; straight coarse glossy black hair; and moustache scanty. Among variations from pe may be mentioned higher stature in some districts, ghter complexion in Tehuantepec and elsewhere. If e native Americans be compared with the races of gions across the oceans to their east and west, it will that their unlikeness is extreme to the races east f them, whether white Europeans or black African other hand they are considerably like the Mongoloid s of North and East Asia (less so to the Polynesians), the tendency among anthropologists is now generally nit a common origin, however remote, between the of Tartary and of America. This original connexion, ay be accepted, would seem to belong to a long past to judge from the failure of all attempts to discover nity between the languages of America and Asia. atever date the Americans began to people America, ust have had time to import or develop the numerous s of language actually found there, in none of which mmunity of origin been satisfactorily proved with er language group, at home or abroad. In Mexico he languages of the Nahua nations, of which the is the best known dialect, show no connexion of with the language of the Otomi tribes, nor either of ith the languages of the regions of the ruined cities tral America, the Quiche of Guatemala and the Maya atan. Indeed, within the Mexican limits, there are other language which, so far as philological h can at present decide, are independent of one . The remarkable phenomenon of nations so in bodily make but so distinct in language can be met except by supposing a long period to have since the country was first inhabited by the rs of peoples whose language has since passed into rent forms. The original peopling of America may te from the time when there was continuous land n it and Asia.

ould not follow, however, that between these remote d the time of the discovery of the New World by ns no fresh immigrants can have reached America. ay put out of the question the Scandinavian sea who sailed to Greenland about the 10th century, and afterwards to have coasted New England (see v, vol. i. p. 706), but do not seem to have found their enough southward for their visit to have any effect ico. But at all times communication has been open ast Asia and even the South Sea islands to the west f America. The importance of this is evident when sider that Japanese junks now drift over by the urrent to California at the rate of about one a year, ith some of the crew still alive (see C. W. Brooks in ft, vol. v. p. 51; *Overland Monthly*, San Francisco, p. 353). Further north, the Aleutian islands offer f easy sea passage, while in north-east Asia, near g's Strait, live Chukchi tribes who carry on inter- with the American side; the presence of Eskimo in rt of Asia (see Nordenskiold, *Voy. of Vega*, vol. ii. pp. 13, so plainly due to local migration that it is neglected paring the languages of the two continents. Asiatics s Japanese or Kurile Islanders, if they found their small numbers to America and merged into native might hardly leave descendants distinguishable he rest of the population even in the first genera or introduce their own language. Such assertions as e Guatusos of Costa Rica are a tribe with fair skin xen hair, and that Japanese words may be detected the Indians of British Columbia, are examples of ce which may be worth further sifting; but in an t like the present no proofs can be admitted unless far authenticated than these. What gives a more solid interest to the question of Asiatic influence in Ame that, though neither the evidence of features nor of la has substantiated it, there are details of Mexican civil which are most easily accounted for on the supposit they were borrowed from Asia. They do not seem enough to have to do with a remote Asiatic origin nations of America, but rather to be results of compar modern intercourse between Asia and America, pr since the Christian era. Humboldt (*Vues des Cor* pl. xxiii.) compared the Mexican calendar with that in eastern Asia. The Mongols, Tibetans, Chines other neighbouring nations have a cycle or series of animals, viz., rat, bull, tiger, hare, dragon, serpent, goat, ape, cock, dog, pig, which may possibly be an tion of the ordinary Babylonian-Greek zodiac fam ourselves. The Mongolian people not only count lunar months by these signs, but they reckon the suc days by them, rat-day, bull-day, tiger-day, &c., and by combining the twelve signs in rotation with th ments, they obtain a means of marking each year sixty-year cycle, as the wood-rat year, the fire-tiger ye This method is highly artificial, consisting, not in numbering, but in combining series of different te that the same combination does not recur till the the period. Thus the reappearance of its principle Mexican and Central American calendar (see p. 212) gestive of importation from Asia. Humboldt also di the Mexican doctrine, represented in the native pictu four ages of the world belonging to water, earth, a fire, and ending respectively by deluge, earthquake, te and conflagration. The resemblance of this to versions of the Hindu doctrine of the four ages or y of so remarkable a closeness as hardly to be accounti except on the hypothesis that the Mexican theolog tains ideas learnt from Asiatics. Among Asiatic pe resemblance to which attention has since been ca the Mexican belief in the nine stages of heaven an an idea which nothing in nature would suggest dire a barbaric people, but which corresponds to the of successive heavens and hells among Brahman Buddhists, who apparently learnt it (in common wi own ancestors) from the Babylonian Greek a trans theory of successive stages or concentric planetary s belonging to the planets, &c. The Spanish chr also give accounts of a Mexican game called *patolli* at the time of the conquest with coloured stones on the squares of a cross-shaped figure, according throws of beans marked on one side, the descripti this rather complicated game correspond closely wi Hindu backgammon called *pachisi* (see Tylor in *Anthrop. Inst.*, vol. viii. p. 116).[1]

The native history of Mexico and Central Ame entitled to more respect than the mere recollecti savage tribes, inasmuch as here memory was aid something like written record. The Mexican pictu far approached writing proper as to set down legi names of persons and places and the dates of events the rude drawings which accompanied these a helped the professional historians to remember the tions repeated orally from generation to generation. actual documents of native Aztec history, or co

[1] The appendix to Prescott's *Conquest of Mexi* con interesting summary of analogies between the civilization of and that of the Old World, but some of the arguments are ver elsewhere. One which has been often cited turns on the likene by Naxera between the Chinese language and that of the Otom of Mexico (whose name survives in that of their town Otompa Otumba). The examination of an Otomi grammar (such as *de la Grammaire Othomi*, Paris, 1863) will, however, conv philological reader that the resemblance is hardly of an an found a theory of a Chinese connexion upon

The district of Yucatan has also some vestiges of native traditions in the manuscript translated by D. Pio (in Stephens, *Incidents of Travel in Yucatan*) and remarkable 16th century *Relacion de las Cosas de Y* by Diego de Landa, published by Brasseur de Bou (Paris, 1864) As in the Guatemala traditions, w of ancient migration from the Mexican legendary of Tula , and here the leaders are four famous ch ancestors , who bear the Aztec name of the Tutul Xiu, interpreted means "Bird Tree Unfortunately f historical standing of these four ancestors , there are Aztec picture writings representation of four tre with a bird perched on it, and placed facing th quarters , which make it probable that the four Tutul tradition, in spite of the circumstantial detail of the and migration may be only mythic personifications four cardinal points (see Schultz Sellack in *Zeitsch. f.* 1879, p. 209) Nevertheless , part of the later Maya may be genuine for instance , when they relate th about three centuries before the Spanish conquest, wh king of Chichen Itza de troyed the great city of Ma Though the name and dates of Central American kings have too little interest to general reader for tra of them to be dwelt on here, they bring into view portant historical point, that the wondrous ruined this region are not to be thought monuments of a race in a forgotten past, but that at least some belong to history, having been inhabited up to the co apparently by the very nations who built them

Turning now to the native chronicles of the N nations, these are found to be quite central dated going back to the 12th or 13th century with some but not worthless recollections of national event from some centuries earlier These last mentioned trad in some measure borne out by linguistic evidence of of place , tribes , and persons, point to the immigra detachments or branches of a wide-spread race , spea common language, which is represented to us Aztec, still a spoken language in Mexico This la was called *nahuatl*, and one who spoke it a hi tongue was called *nahuatlecatl*, so that modern pologists are following native precedent when they term *Nahua* for the whole serie of people now consideration[1] Earliest of the Nahua nations, the are traditionally related to have left their norther of Huehuetlapallan in the 6th century and, thou remote date cannot be treated as belonging to hi tory, there is other evidence of the real existence nation Their name *Toltecatl* signifies an inhabi *Tollan*, "land of reeds," a place which, as has been pointed out, appears elsewhere in the national tradit this region, and has a definite geographical site present Tulan or Tula, north of the valley of A where a Toltec kingdom of some extent seems to ha its centre. To this nation is ascribed not only the but the highest culture of the Nahua nations , t was due the introduction of maize and cotton into the skilful workmanship in gold and silver, the art o ing on a scale of vastness still witnessed to by the m Cholula, and to be Toltec work , the Mexican hiero writing and calendar are also declared to have Toltec origin. With the Toltecs is associated the mys tradition of Quetzalcoatl, a name which presents i Mexican religion as that of a great deity, god of and in legend as that of a saintly ruler and civilize brown and beardless , worshippers describe him as of race, a white man with noble features, long black h full beard, dressed in flowing robes . He came from

[1] It should be noticed that this word is not etymologic nected with the somewhat similar word *Anahuac*, of which t ing is given at page 206

n Yucatan (for the stories differ widely), and dwelt
years among them, teaching men to follow h
and virtuous life, to hate all violence and war, to
e no men or beasts on the altars, but to give mild
gs of bread and flowers and perfumes, and to do
e by the votaries drawing blood with thorns from
wn bodies. Legend tells stories of his teaching men
writing and the calendar, and also the arts of work
silversmith, for which Cholula was long famed. Last
he departed, some say towards the unknown land of
an, but others to Coatzacoalco on the Atlantic coast
confines of Central America where native tradition
eps up the divine names of Cucumatz among the
s (see p. 208) and Cukulcan among the Mayas, these
having the same meaning as Quetzalcoatl in Aztec,
Feathered Serpent.' Native tradition held that
Quetzalcoatl reached the Atlantic he went back in
ion to tell he Cholulans that in a future year he
n, white men and bearded like himself, would land
rom the sea where the sun rises and come to rule
ntry. That there is a basis of reality in the Toltec

ons is shown by the word *toltecatl* having become
the later Aztecs a substantive meaning an artist
ed craftsman. It is further related by the Mexican
ns that the Toltec nation all but perished in the
entury by years of drought famine, and pestilence,
nly of the survivors remaining in the land, while the
grated into Yucatan and Guatemala, where, as has
eady pointed out, their name is commemorated in
ecords. After the Toltecs came the Chichimecs,
name, derived from *chichi*, "dog," is applied to
rude tribes, the Chichimecs here in question are
have come from Amaquemecan under a king named
names which hence Aztec imply that the nation
ahua; at any rate they appear afterwards as fusing
ore cultured Nahua nations in the neighbourhood
neco. Lastly is recorded the Mexican immigration
seven nations, Xochimilca, Chalca, Tepaneca,
a, Tlahuica, Tlascalteca, Aztaca. This classification
Nahuatlac tribes has a meaning and value. It is
at Aztlan, the land whence the Aztecs traced their
nd source, cannot be identified by geographers, while
ry of the separation of the seven nations at the place
Chicomoztoc or Seven Caves looks like national legend
than real history. But the later stages of the long
migration seem historical, and the map of Mexico
ows the names of several settlements recorded in the

migration map published by Gemelli Careri (*Giro*
ndo, Venice, 1728) and commented on by Humboldt;
these local names are Tzompan, "place of skulls,"
mpango in the north of the Mexican valley, and
tepec, "grasshopper hill," now a suburb of the city
ico itself, where the Aztecs are recorded to have
ted in 1195 the festival of tying up the "bundle of
and beginning a new cycle. The Aztecs moving
lace to place in Anahuac found little welcome from
hua peoples already settled there, whose own history
leed one of incessant jealousy and quarrel. One of
st clear events of the Aztec arrival is their being
tributary by the Tepanecs, in whose service
they began to manifest their warlike prowess
ht near Tepeyacac, where now stands the famous
of Our Lady of Guadalupe. Thus they overcame in
he Acolhuas, their superiors in civilization, who had
Tezcuco a centre of prosperity and improvement.
13th century the Aztecs by their ferocity had
their neighbours together against them; some
driven to take refuge on the reedy lake shore at
co, while others were taken as captives into
ican. The king of this district was Coxcoxtli,

y the sacrificing priests to propitiate a pantheon of gods ho well personified their bloodthirsty worshipper. The sire for war captives as acceptable victims is related to ave brought about an almost incredible agreement among ation of the Mexican alliance, that they should from me to time fight battles among themselves in order to rovide prisoners for the altars. Thus there was something the character of a religious war in the expedition made 1469 under Axayacatl as far down the isthmus as ehuantepec, whence the Mexican army came back with ad of rich plunder and thousands of captives, and the ter ravages of the Totonac recorded as far as the Atlantic, hen the inhabitants were taken for sacrifice and their nd recolonized by Aztec. Montezuma left the Aztec mpire (as it is often somewhat ambitiously called) at the eight of apparent power but the cruel oppression of the ubject regions had made their life almost unbearable, and he second Montezuma, coming to a rule already labile to reak up from within, weakened it still more by upholding he claims of chief or noble against the common people hose warrior and trader had in great measure made

he property of the allied nations. The Mexican had ng tried to subjugate the stubborn little nation of Tlax llan (Tlaxcala) which had obstinately held out, though so ommanded in their very midst the people lived without salt, this ing no longer to be had from the sea coast. Montezuma ade a last effort to crush them, but in vain, and when he Spaniard came they were there as ready made allies anted on the high road to Mexico. From the date when he festival of the new cycle was first celebrated in hapultepec (a 52 year period) had passed when in 1507 he new fire, symbolizing the beginning of a new cycle as kindled for the last time on the breast of a human ictim. Rumours of the coming of the Europeans may ave before the date spread from Cuba, but in 1517 ordova touched in Yucatan, and in 1518 Grijalva was n the east coast of Mexico, and the Aztecs first met the hite men in whom they saw (partly with hope and partly ith fear) the fulfilment of the prophecy that Quetzalcoatl ould one day return. With the Spanish conquest under ernando Cortes (see Cortes) the native history of Mexico me to an end.

Civilization

While the purer tribes of America lived under the loose ay of chiefs and councils of old men, the settled nations of exico had grown to a somewhat highly organized government his may be seen by the elaborate balance of power maintained in he federation of Mexico, Tezcuco and Tlacopan, where each king

been more remarkable for number and extent than architectu grandeur, being but low one-storied buildings. The princip palace of Mexico consisted of hundreds of rooms and halls rang round three open squares, with women's apartments, granari storehouses, menagerie, aviaries, of such extent that one of t companions of Cortes records having four times wandered abo till he was tired, without seeing the whole. Not less rema able was the palace of Tezcuco, surrounded with its groves a pleasure gardens, and, though now hardly anything remains of t building above ground, the neighbouring hill of Tezcotzinco st has its stone steps and terraces, and the immense embankme carrying the aqueduct-channel of hewn stone which supplied wa to bear out in the solid rock still remains to prove that the chr nicles' descriptions, if highly-coloured, were at any rate genuine. T the 15th century the equestrian figures of Axayacatl and his son Mon zuma were to be seen carved in the porphyry hill of Chapultep but these as well as the hanging gardens have been destroyed, a only the groves of *ahuehuetl* (cypresses) remain of the ancient beaut of the place. That in the palace gardens flowers from the tie caliente were transplanted, and water-fowl bred near fresh and s pools fit for each kind, that all kinds of birds and beasts were k in well appointed zoological gardens where there were homes ev for alligators and snakes—all these testifies, not merely to barba ostentation, but to a cultivation of natural history which was re beyond the European level of the time. From the palaces and temples of thousands of servants attached to the royal service may

inherited at once the despotic power of the Mexican rulers and t heavy taxation of the people, in fact some of the most remarka of the picture writings are tribute rolls, enumerating by hundr and thousands the mantles, ocelot-skins, bags of gold dust, bro hatchets, loads of chocolate, &c., furnished periodically by the tow Below the king was a numerous and powerful class of nobles hitherto of whom (*tlatoani*) were great vassals owing little more th homage and tribute to their feudal lord, while the natural re of the multiplication of the noble class was that the king to keep th in check increased their numbers, brought them to the capital courtiers, and balanced their influence by military and household officers, and by a rich and powerful merchant class. The nob not only had privileges of rank and dignity, but substantial pow over the plebeian or peasant class (*macehualtin*), who submitted much the same oppression and extortion at their hands as w customary in the Old World. The tenures of land in Mexico w those generally appearing in barbaric countries where invasion a military despotism have encroached on but not totally supersed the earlier tribal laws. The greatest estates belonged to the kin or had been granted to military chiefs whose sons succeeded the or were the endowments of temples, but the *calpulli* or villa community still survived, and each freeman of the tribe held a tilled his portion of the common lands. Below the freemen w the slaves, who were war-captives, persons enslaved for punishme or children sold by their parents. Prisoners of war were mos doomed to sacrifice, but other classes of slaves were mildly treate retaining civil rights, and their children were born free.

The superior courts of law formed part of the palace, and th were tribunals in the principal cities, over each of which presided supreme judge or *cihuacoatl*, who was irremovable, and wh criminal decisions not even the king might reverse; he appoint the lower judges and heard appeals from them; it is doubt whether he judged in civil cases, but both kinds of suits were he in the court below, by the *tlacatecatl* and his two associates, bel whom were the ward-magistrates. Lands were set apart for t maintenance of the judges, and indeed nothing gives a higher i of the elaborate civilization of Mexico than this judicial syste which culminated in a general court and council of state presi over by the king. The laws and records of suits were set down picture writings, of which some are still to be seen, sentence death was recorded by drawing a line with an arrow across portrait of the condemned, and the chroniclers describe the barba solemnity with which the king passed sentence sitting on a gold and jewelled throne in the divine tribunal, with one hand on ornamented skull and the golden arrow in the other. Among t resemblances to Old World law was the use of a judicial oath, t witness touching the ground with his finger and putting it to lips thus swearing by Mother Earth. The criminal laws were extreme severity, even petty theft being punished by the thief bei stoned to the person he had robbed, while to steal a tobac pouch or twenty ears of corn was death; he who pilfered in t market was then and there beaten to death, and he who insulted Xi the god of the gold and silver smiths, by stealing his precious met was skinned alive and sacrificed to the offended deity. Thou also beer or "pulque" was allowed for feasts and to invalids moderation, and old people over seventy seem to be represent in one of the picture-writings as having liberty of drunkenne young men found drunk were clubbed to death and young wom stoned. Such a Draconian standard prevailing, it is hardly need to enumerate the special penalties of such offences as witchera fraud, removing landmarks, adultery, &c., which differed as

whether the criminal had his heart cut out on the altar, his head crushed between two stones, &c.; while even lesser punishments were harsh, such as that of slanderers, whose hair was singed with a pine torch to the scalp.

Based on conquest as the Aztec kingdom was, and with the craving for warlike glory fostered by the most bloodthirsty religion the world ever saw, it follows that the nation was above all other pursuits organized as a fighting community. To be a great soldier was the road to honour and office, and the king could not be enthroned till he had with his own hand taken captives to be butchered on the war-god's altar at his coronation. The common soldiers were promoted for acts of daring, and the children of chiefs were regularly trained to war, and initiated by being sent into battle with veterans, with whose aid the youth took his first prisoner, but his future rise depended on how many captives he took unaided in fight with warlike enemies; by such feats he gained the dignity of wearing coloured blankets, tassels, and lip-pewter, and reached such military titles as that of "guiding eagle." The Mexican military costumes are to be seen in the pictured writings, where the military orders of princes, eagles, and tigers are known by their braided hair, eagles' beaks, and spotted armour. The common soldier went into battle brilliant in savage war-paint, but those of higher rank had helmet-like head and beaks of prey, armour of gold and silver, wooden greaves, and especially the *ichcahuipilli*, the quilted cotton tunic two fingers thick, so serviceable as a protection from arrows that the Spanish invaders were glad to adopt it. The archers shot well and with strong bows, though their arrows were generally tipped only with stone or bone, their shields or targets, mostly round, were of ordinary barbaric forms, the spears or javelins had head of obsidian or bronze, and were sometimes hurled with a spear-thrower or *atlatl*, of which pictures and specimens still exist, showing it to be similar in principle to those used by the Australian and Eskimo. The most characteristic weapon of the Mexicans was the *macquauitl* or "sword wood," a club set with two rows of large sharp obsidian flakes, a well directed blow with which would cut down man or horse. These two last-mentioned weapons have the look of highly developed savage forms, while on the other hand the military organization was in some respects equal to that of an Asiatic nation, with its regular companies commanded each by its captain and provided with its standard. The armies were very large, an expedition often consisting of several divisions each numbering eight thousand men, but the tactics of the commanders were quite rudimentary, consisting merely of attack by arrows and javelins at a distance gradually closing into a hand to hand fight with clubs and spears with an occasional feigned retreat to draw the enemy into an ambuscade. Fortification was well understood, as may still be seen in the remains of walled and escarped strongholds on hills and steep ravines, while lagoon cities like Mexico had the water approaches defended by fleets of boats, and the causeways protected by towers and ditches. Even after the town was entered, the pyramid-temples with their surrounding walls were fortresses capable of stubborn resistance. It was held unrighteous to invade another nation without a solemn embassy to warn them of the miseries to which they exposed themselves by refusing the submission demanded, and this again was followed by a declaration of war, but in Mexico as in other more cultured countries this act of national morality degenerated into a ceremonial farce, where tribute was claimed from some neighbouring nation, or an Aztec god was offered to be worshipped in their temples, in order to pick a quarrel as a pretext for an invasion already planned to satisfy the soldiers with lands and plunder, and to meet the priests' incessant demands for more human sacrifices.

Among the accounts of the Mexican religion are some passages referring to the belief in a supreme deity. The word *teotl* god, has been thought in some cases to bear this signification, but its meaning is that of deity in general, and it is applied not only to the sun-god but to very inferior gods. It is related that Nezahualcoyotl, the poet king of Tezcuco, built a nine-storied temple with a starry roof above, in honour of the invisible deity called Tloquenahuaque, "he who is all in himself," or Ipalnemoan, "he by whom we live," who had no image, and was propitiated, not by bloody sacrifices, but by incense and flowers. Those who adopt the opinion of Asiatic admixture in Mexican culture will use it to account for this remarkable religious phenomenon, less easily accounted for by native development, while also the appearance of a rival deity of evil, bearing the name of Tlacatecolotl, or "man-owl," is mysterious. These divinities, however, seem to have had little or no place in the popular faith, which was occupied by polytheistic gods of more ordinary barbaric type. Tezcatlipoca was held to be the highest of these, and at the festival of all the gods his footsteps were expected to appear in the flour strewn to receive this sign of their coming. He was plainly an ancient deity of the race, for attributes of many kinds are crowded together in him, and he was prayed to in interminable formulas for help in war and for health and fortune, to deliver the nation from a wicked king, or to give pardon and strength to the penitent who had confessed his sins and been purified by washing. Between him and Quetzalcoatl, the ancient deity of [illegible] there had been old rivalry, as is related in legends of Quetzalcoatl coming into the land to teach men to till the soil, to work metals, to rule a well-ordered state; the two gods played their game at the ball game, and Tezcatlipoca, in the guise of a hoary sorcerer, persuaded the sick and weary Quetzalcoatl to drink the magic pulque that sent him roaming to the distant ocean, where he embarked in his boat and disappeared from among men. The deities are not easily analysed, but on the other hand Tonatiuh, Metztli the sun and moon, stand out in the distinctest personality as nature gods, and the traveller still sees in the huge adobe pyramids of Teotihuacan, with their sides oriented to the four quarters, evidence of the importance of their worship. The war god Huitzilopochtli, of whom one legend relates a supernatural conception in the ancient Tulian, while another story declares him to have been (like the Chinese war-god) a deified warrior chief, was the great god of the Aztec pantheon, his idol remains in Mexico, a huge monolith on which is sculptured on the one side his hideous portrait adorned with the humming bird feathers on the left half, the serpent his name, while the not less frightful war goddess Coatlicue, or "divine war death," occupies the other side. Tlazolteotl the goddess of the all nourishing maize was patroness of childbirth and mother of the gods, while Mictlantecuhtli, lord of darkness, ruled over the departed in the dim under-world. Numerous lesser deities presided over classes of society, events, and every act of life such as Tlaelcuani goddess of pleasure, wife of the amorous Tezcatzoncatl, god of strong drink, whose garments in irony clothed the drunkard's corpse, and Xipe, patron of the goldsmiths. Below these were the numerous crowd of nature spirits of mountain and grove, whose shrines were built by the road side to receive offerings from passers by. The temples were called *teocalli* or 'god's house,' and the teocallis of the greater deities rivalled, as they resembled in form the temple of ancient Babylon, were pyramids on a square or oblong base, rising in successive terraces to a small summit-platform. The great temple of Huitzilopochtli in the city of Mexico stood in an enclosed square, whence radiated the four principal thoroughfares of the city, and being enclosed by a square, or rather oblong wall, called the *coatepantli* or serpent wall from its sculptured serpents, measured nearly a quarter of a mile on each side. In the centre, the oblong pyramid of rubble cased with hewn stone and cemented, 375 × 300 feet at the base, and rising steeply in six terraces to the height of 86 feet, showed conspicuously to the people the long pacing figures of priests and victims winding round the terraces and up the corner flights of steps. On the paved platform were three-story tower temples in whose ground floor stood the sacred images and altars, and before that of the war-god the great sacrificial stone, humped so as to bend upward the body of the victim that the priest might more easily slash open the breast with his flint knife tear out the heart and hold it up before the god, while the captor and his friends were waiting below for the carcass to be tumbled down the steps for them to carry home to be cooked for the feast of victory. Before the shrines rocking with the din of the slaughter, the eternal fires were kept burning, and on the platform stood the huge drum covered with snakes' skin whose hollow boom was heard for miles. From the terrace could be seen some fifty more other temples within the enclosure, with their numerous blazing fires, and the *tzompantli* or 'skull-place,' where the skulls of victims by tens of thousands were skewered on cross-beams built into towers. There also might be seen the flat sacrificial stone *temalacatl* or "spindle stone," where captives armed with feathered weapons were allowed the mockery of a gladiatorial fight with well-armed champions. The great pyramid of Cholula, with its hemispherical temple of Quetzalcoatl at the top, a huge almost shapeless hill surmounted by a church, was also as long and twice as high as the teocalli of Mexico. A large fraction of the Mexican population were set apart as priests and attendants to the services of the gods. The rites performed such as are found elsewhere, prayer, penitence, processions, dances, chants, fasting and other austerities, but there are some curious touches of detail. Prayer and other formulas have been copied by Sahagun and other chroniclers, of endless prolixity, but without occasional touches of pathos. The following sentences from a prayer to Tezcatlipoca, intercessor for the people, are characteristic: "O our lord, protector most strong and compassionate, invisible and impalpable, thou art the giver of life; lord of the day, lord of battles, I present myself here before thee to say [illegible] concerning the need of the poor people, the people of no understanding [illegible] Know, O Lord, that thy subjects and vassals suffer a sore poverty, that cannot be told of nor described, for it is a sore poverty and desolateness. The men have no mantles, nor the women to cover themselves with, but only rags to cover every part that let the wind and cold in. [illegible] If they cry their chants, they now sell only cakes of salt and broken pepper, for the people that have something despise their wares, so that they go and sell from door to door and from house to house; and when they get nothing they sit down sadly by some fence or wall, or [illegible] some

icking their lips and gnawing their nails for the hunger that is in hem, they look on one side and the other at the mouths of those who pass by, hoping peradventure that one may speak one word to them. O compassionate God, the bed on which they lie is not a thing to rest upon, but to endure torment in; they draw a rag over them at night and so sleep. . . . O our Lord, in whose power it is to give all content, consolation, sweetness, ottine, prosperity, and riches, for thou alone art lord of all good, have mercy upon them, for they are thy servants. . . . I supplicate thee that thou wilt lift up their head with thy favour and aid, that thou wilt see good that they enjoy some day of prosperity and tranquillity, so that they may sleep and know repose, having prosperous and peaceable days of rule. . . . Should the nation for whom I pray and entreat thee to do them good not render good what thou hast given, thou canst take away the good and pour out cursing, so that all evil may come upon them, and they become poor in need, maimed, lame, blind, and deaf, then indeed they shall waken and know the good that they had and have not; and they shall call upon thee and lean toward thee, but thou wilt not listen, for in the day of abundance they would not acknowledge thy goodness towards them." These prayers seem entirely genuine, indeed there was no European model from which they could have been imitated, but at the same time it must be remembered that they come down in Spanish writing, and not untouched by Spanish influence, as in one passage where there is a mention of sheep, an animal of course unknown to the native Mexican. As to sacrifices, maize and other vegetables were as well offered and occasionally rabbits, quails, &c., but, in the absence of cattle, human sacrifice was the chief rite, and cannibalism prevailed at the feasts. Incense was constantly used, especially the *copalli* or copal well known to us for varnish, little terra cotta censers are among the commonest of Mexican antiquities. Long and severe penitential fasts were customary at special seasons, and drawing blood from the arms, legs, and body, by thrusting in aloe thorns and passing sharp sticks through the tongue, was an habitual act of devotion recalling the similar practices of devotees in India. The calendar of religious festival for the whole course of the Mexican year has been preserved. Each 20-day period had one or more such celebration. In the month of the "diminishing of waters," the rain gods or Tlaloc were propitiated by a procession of priests with music of flutes and trumpets carrying on plumed litters infants with painted faces, in gay clothing with coloured paper wings, to be carried on the mountains or in a whirlpool in the lake. It is said that the people wept as they passed by, but it so that must have been a customary formality, for the religion of the nation must have quenched all human sympathy. In the next month the god Xipe totec, already mentioned, had his festival called the "flaying of men" from the human victims being flayed, after their hearts were torn out, for young men to dress in their skins and perform dances and sham fights. The preceding festival of Camaxtli was marked by a severe fast of the priests, after which stone knives were prepared with which a hole was cut through the tongue of each, and numbers of sticks passed through. For the great festival of Tezcatlipoca, the handsomest and noblest of the captives of the year had been chosen as the incarnate representative of the god, and paraded the streets for public adoration dressed in a rich costume with feathers and garlands on his head and a retinue like a king, for the last month they married him to four girls representing the goddesses; on the last day wives and priests escorted him to the little temple of Tlacochcalco, where he mounted the stairs, breaking his earthenware flute against each step, this was a symbolic farewell to the joys of the world, for as he reached the top he was thrown by the priests, his heart torn out and held up to the sun, his head impaled on the tzompantli, and his body eaten as sacred food by the people drawing from his fate the moral lesson that riches and pleasure may turn into poverty and sorrow. The manner of the victim's death in these festivals afforded scope for variety, they dressed them and made them dance in character, threw them into the fire for the fire-god, or crushed them between two balanced stones at the harvest festival. The ordinary pleasures of festivals were mingled with all this, such as dances in beast-masks, chivalry fights, and children's games, but the type of a religious function was a sickening butchery followed by a cannibal feast.

The Mexican priesthood, being the educated class, were much concerned with the art of picture writing which they had developed to a stage quite above the rude figures of the American hunting-tribes, and used systematically as a means of recording religious festivals and legends as well as keeping calendars of years and recording the history of events which occurred in them. Facsimiles of several of these interesting documents, with their translations, may be seen in Kingsborough. On inspecting these it will be seen that their main principle is pictorial. Gods are represented with their appropriate attributes, the fire-god hurling his spear, the moon-goddess with a shell, &c. The scenes of human life are pictures of warriors fighting with club and shield, men paddling in canoes, women spinning and weaving, &c. An important step towards phonetic writing appears, however, in the picture names of places and persons. The simplest forms of these depict the objects signified by the name, as where *Chapultepec* or "grasshopper hill" is represented by a grasshopper on a hill, or a stone with a cactus on it stands for *Tetzcoco* or "stone cactus," the founder of *Tenochtitlan*. The system has, however, risen a stage beyond this when objects were drawn to represent, not themselves, but the syllables forming their names, as where a trap an eagle, a pricker, and a hand are put together not to represent these objects, but in order that the syllables of their names *mo quauh-tzo ma* should spell the word Moquauhzoma (see Aubin's introduction to Brasseur, *Hist du Mexique*, vol. i. p. lviii.). The analogy of this to the manner in which Egyptian hieroglyphs passed into phonetic signs is remarkable, and writing might have been invented anew in Mexico had it not been for the Spanish conquest. The Aztec numerals, which were expressed or reckoned by scores, were depicted by dots or circles up to 20, which was represented by a flag, 400 a score of scores by a feather, and 8000 a score of scores of scores by a purse; for convenience these symbols might be halved and quartered, so that 531 might be shown by one feather, one quarter of a feather, one flag, one half of a flag, and four dots. The Mexican calendar depended on the combination of numbers with picture signs, of which the four principal were the rabbit, reed, flint, house, *tochtli, acatl, tecpatl, calli*. The cycle of 52 years was reckoned by combining these signs in rotation with numbers up to 13, thus 1 rabbit, 2 reed, 3 flint, 4 house, 5 rabbit, 6 reed, &c. By according this calendar may be exactly illustrated with a modern pack of cards laid out in rotation of the four suits, ace of hearts, 2 of spades, 3 of diamonds, 4 of clubs, 5 of hearts, 6 of spades, &c. The Mexican ritual calendar of the days of the year, the same method carried further, the series of twenty day signs being combined in rotation with numbers up to 13; as this cycle of days only reaches 260, a series of nine other signs are affixed in addition to make up the 365 day year. It is plain that this rotation of signs served no useful purpose whatever, being less convenient than the ordinary counting such as the Mexicans employed in their other calendar already mentioned, where the 20 day periods had each a name like our months, and their days had signs in regular order. The historical interest depends on its resemblance to the calendar systems of central and eastern Asia, where among Mongols, Tibetans, Chinese, &c., series of signs are thus combined to reckon years, months, and days, for instance, the Mongol cycle of 60 years is recorded by the zodiacal series of 12 signs—mouse, bull, tiger, &c.—combined in rotation with the five male and female elements—wood, earth, iron, water, wood; as "male-fire bull" year, &c. The comparison is worked out in Humboldt's *Vues des Cordillères*, as evidence of Mexican civilization being borrowed from Asia. Naturally the Mexican calendar system lent itself to magic in the same way as the similar zodiacal signs of the Old World, each person's fate being affected by the qualities of the signs he was born under, and the astrologer priests being called in to advise on every event of life. Of all Mexican festivals the most solemn was that of the *xiuhmolpilli*, or "year binding," when the current cycle or bundle of years came to an end. It was believed that the destruction of the world, which after the Hindu manner the Mexicans held to have already taken place three or four times, would happen again at the end of a cycle. As the time drew near, the anxious population cleansed their houses and put out all fire, and on the last day after sunset the priests, dressed in the garb of gods, set out in procession for the hill of Huixachtla, there to watch for the approach of the Pleiades to the zenith, which was the auspicious signal for the lighting of the new fire. The breast of the captives was thrown down and fire kindled on his breast in the wooden drill of the priest; then the victim's heart was torn out and his body flung on the pile kindled with the new flame. The people watching from their flat housetops all the country round saw with joy the flame on the sacred hill, and hailed it with the thank offering of drops of blood drawn from their ears with sharp stone flakes. Swift runners carried burning brands to rekindle the fires of the land, the sacred fire on the teocalli of the war god blazed up again, and the people began with feasting and rejoicing the new cycle.

Mexican education, at any rate that of the upper class, was a systematic discipline much under the control of religion, which here presents itself under a more favourable light. After the birth of a child, the *tonalpouhqui* or "sun-calculator" drew the horoscope from the signs it was born under, and fixed the time for its solemn lustration or baptism, performed by the nurse with appropriate prayers to the gods, when a toy shield and bow were provided if it was a boy, or a toy spindle and distaff if it was a girl, and the child received its name. An interesting picture writing may be seen in Kingsborough, shows the details of the boy's and girl's education, from the early time when three small circles over the child show it to be three years old, and a drawing of half a tortilla or corn cake shows its allowance for each meal: as they grow older the lads are seen beginning to carry burdens, paddle the canoe and fish, while the girls learn to spin and weave, grind maize, and cook,—good conduct being enforced by punishments of increasing severity, up to pricking their bodies with aloe-thorns and hold

heir faces over burning chillis. The schools were extensive buildngs attached to the temples, where from an early age boys and irls were taught by the priests to sweep the sanctuaries and keep up he sacred fires, to fast at proper seasons and draw blood for penance, nd where they received moral teaching in long and verbose formulas hose fit for a soldier's life were trained to the use of weapons nd sent early to learn the hardships of war, children of craftsmen vere usually taught by their fathers to follow their trade; and for he children of nobles there was elaborate instruction in history, icture writing, astrology, religious doctrines, and laws. Marriage epended much, as they do still in the East, on comparison of the oroscopes of the pair to ascertain if their birth-signs were comatible. Old women were employed as go-betweens, and the arriage ceremony was conducted by a priest who after moral xhortations united the young couple by tying their garments ogether in a knot, after which they walked seven times round the re, casting incense into it, after the performance of the marriage eremony the pair entered together on a four days' fast and enance before the marriage was completed. The funeral rites f the Mexicans are best seen in the ceremonies at the death of a ing. The corpse laid out in state was provided by the priest with jug of water for his journey, and with bunches of cut papers to ass him safely through each danger of the road: the place where he two mountains strike together, the road guarded by the great nake and the great alligator, the eight deserts and the eight alls; they gave him garments to protect him from the cutting vind, and buried a little dog by his side to carry him over the ine waters. Then the royal body was invested in the mantle of is patron-gods, especially that of the war-god, for Mexican kings vere warriors: on his face was placed a mask of turquoise mosaic, nd a green chalchihuite stone as a heart between his lips. In older imes the dead king was burned on a throne with his property and lead attendants round him. But after cremation came in a nourning procession of servants and chiefs carried the body to the uneral pyre to be burnt by the demon-dressed priests, after which he crowd of wives and slaves were exhorted to serve their lord aithfully in the next world, were strangled and their bodies burnt. Common people would not thus be provided with a ghostly retinue, ut their simpler funeral ceremonies were as far as they went similar o those of their monarch.

The staple food of the Mexicans before the conquest has continued ith comparatively little change among [illegible] and has ven been adopted by those of European blood. Maize or Indian orn was cultivated on patches of ground where, as in the Hindu *dm*, the trees and bushes were burnt and the seed planted in the oil manured by the ashes. A sharp-pointed planting stick, a ooden shovel, and a bronze-bladed hoe called a *coatl* were the mple implements. The Mexicans understood digging channels o irrigation, especially for the cultivation of the *cacahuatl*, from hich they taught the Europeans to prepare the beverage *chocollatl*; hese native names passed into English as the words cacao, or cocoa, nd chocolate. Other vegetables adopted from Mexico are the tomata *omatl*) and the *chilli*, used as flavouring to native dishes. The aize was ground with a stone roller on the grinding stone or *metlatl*, till known over Spanish America as the *metate*, and the meal baked nto thin oval cakes called by Aztecs *thaoalli*, and by Spaniards *ortilla*, which resemble the *chapati* of India and the oat-cake of Scotland. The Mexicans were also skilful makers of earthen pots, n which were cooked the native beans called by the Spanish *frijoles*, nd the various savoury stews still in vogue. The juice extracted by tapping the great aloe before flowering was fermented into an intoxicating drink about the strength of beer, *octli*, by the Spaniards called *pulque*. Tobacco, smoked in leaves or cane pipes or taken as snuff, was in use, especially at feasts. It is related that n old times Mexican clothing was of skins or woven aloe and palm ibre, but at the time of the conquest cotton was largely cultivated n the hot lands, spun with a spindle, and woven in a rudimentary oom without a shuttle into the mantles and breech cloths of the nen and the chemises and skirts of the women, garments often of ine texture and embroidered in colours. Ornaments of gold and ilver, and jewels of polished quartz and green chalchihuite were vorn,—not only the ears and nose but the lips being pierced for ornaments. The artificers in gold and silver melted the metals by neans of a reed blowpipe and cast them solid or hollow, and were also skilled in hammered work and chasing, as some fine specimens remain to show, though the famous animals modelled with gold and ilver fur, feathers, and scales have disappeared. Iron was not known, but copper and tin ores were mined, and the metals combined into bronze of much the same alloy as in the Old World, of which hatchet blades and other instruments were made, though their use had not superseded that of obsidian and other sharp stone lakes for cutting, shaving, &c. Metals had passed into a currency for trading purposes, especially quills of gold dust and T-shaped pieces of copper, while cocoa beans furnished small change. The vast size of the market-squares with their surrounding porticos, and the importance of the caravans of merchants who traded with other nations, show that mercantile had risen into some proportion to military interests. Nor was the wealth and luxury of Mexico an surrounding regions without a corresponding development of ar The stone sculptures such as that remaining at Xochicalco which figured by Humboldt, as well as the ornamented woodwork, feathe mats, and vases, are not without artistic merit. The often cite poems attributed to Nezahualcoyotl may not be quite genuine, bu at any rate poetry had risen above the barbaric level, while th mention of ballads among the people, court odes, and the chants temple choirs would indicate a vocal cultivation above that of t instrumental music of drums and horns, pipes and whistles, t latter often of pottery. Solemn and gay dances were frequent, an a sport called the bird dance excited the admiration of foreigne for the skill and daring with which groups of performers dressed bird-like themselves down by ropes wound round the top of a hig mast, so as to fly whirled in circles far above the ground. Th ball-game of the Mexicans called *tlachtli*, was, like tennis, the pa time of princes and nobles, special courts were built for it, and th ball of india-rubber (perhaps the first object in which Europea became acquainted with this valuable material might not be touche by the hands, but was driven against the walls by blows of the kn or elbow, shoulder or buttock. The favourite game of *patolli* has bee already mentioned for its similarity to the *pachisi* of modern Indi

The accounts given by Spanish writers of the Central Americ in their state after the Spanish conquest are very scanty in com parison with the voluminous descriptions of Aztec life. They bra out perfectly, however, the fact of close connexion between the tw civilizations. Some Central-American peoples were actually Mexic in their language and culture, especially the Pipils of Guatemala an a large part of the population of Nicaragua, but there were descen ants of Aztecs or allied peoples who in the comparatively moder times of Aztec power invaded and colonized these distant countri (see Buschmann, *Aztek. Ortsnamen*, xviii., xx.). With regard to th Central American nations proper, especially the Mayas of Yucat and the Quiches of Guatemala, who dwelt in the cities and wo shipped in the temples of Chichen Itza and Uxmal, Palenque an Copan, the problem of Aztec connexion is deeper and obscure How closely related these nations were in institutions to t Mexicans appears, not only in their using the same peculiar weapon such as the spear-thrower and the toothed club or maquahuitl, b in the similarity of their religious rites such as drawing blood fr their bodies as an act of penance and sacrificing human victims cutting open the breast and to[illegible] heart, the connexion evident in such special points as the ceremony of marriage by tyi together the garments of the couple, or in holding an offender's ha over burning chillis as a punishment, the native legends of Centr America make mention of the royal ball-play, which was the sam as the Mexican game of tlachtli already mentioned. At the sam time many of the Central-American customs differed from t Mexican; thus in Yucatan we find the custom of the youths sleepi in a great bachelor's house, an arrangement common in variou parts of the world, but not in Mexico, the same remark applies the Maya exogamous law of a man not taking a wife of his ow family name (see Diego de Landa, *Relacion de Yucatan*, Brasseur de Bourbourg, p. 140), which does not correspond wi Mexican custom. We have the means of comparing the person appearance of the Mexicans and Central Americans by their po traits on early sculptures, vases, &c.; and, though there does n appear any clear distinction of race type, the extraordinary bac sloping foreheads of such figures as those of the Las Ichet of Palenq prove that the custom of flattening the skull in infancy prevail in Central America to an extent quite beyond any such habit Mexico. It is from the ruined cities now buried in the Centra American forests that we gain the best information as to the natio who built them. The notion sometimes propounded that the famous cities were of great antiquity and the work of extinct natio has no solid evidence, some of them may have been already aba doned before the conquest, but others were inhabited, and by t ancestors of the Indians who now build their mean huts and t their patches of maize round the ruins of the grander life of th ancestors. In comparing these ruins through the districts Yucatan, Chiapa, Guatemala, and Honduras, it is evident tha though they are not the work of a single nation, but of two or mo highly distinct in language, yet these nations had the great bo of a common system of pictorial or written characters. One spe men of a Central American inscription may give a general idea them all, whether it be from the sculptured façade of a temp sketched by Catherwood, or from the painted deer-skin called t Dresden Codex reproduced in Kingsborough, or from the chapt of Diego de Landa where he professes to explain and translate t characters themselves. These consist of combinations of faces, circl lines, &c., arranged in compartments in so complex a manner th hardly two are found alike. How they conveyed their meanin how far they pictorially represented ideas or spelt words in t different languages of the country, is a question not yet answer in a complete way; Landa's description (p. 320) gives a table of number of their elements as phonetically representing letters syllables, but, though there may be a partial truth in his rules, th

e too insufficient or too erroneous to serve for any general decipher ent Most of what has been written on this enticing subject is orthless, but a promising attempt has been made by E. S. Holden, ho has analysed the combined figures into their elementary lines *First Annual Report of Bureau of Ethnology*, Smithsonian Insti- ution, Washington, 1881; Cecil de Charency, *Melanges de Philologie de Paléographie Américaines*, Paris, 1883. One point as to the entral-American characters is clear, that part of them are calendar gns recording dates From the accounts given by Landa and other riters it is plain that the Central American calendar, reckoning he year in twenty-eight periods of thirteen days, was the same in s principle of combining signs as that of Mexico here mentioned t page 212 The four leading Maya signs called *kan*, *muluc*, *ix*, *cauac* orresponded in their position to the four Aztec signs rabbit, reed, int, house, but the meanings of the Maya signs are, unlike the ztec, very obscure A remarkable feature of the Central-American ins is the frequency of truncated pyramids built of hewn stone, ith flights of steps up to the temple built on the platform at top. he resemblance of these structures to the old descriptions and pic habitu- lly given to them The teocallis built by the Nahua or Mexican ation have been mostly destroyed, but two remain at Huatusco nd Tuspan figured in " t, vol iv. pp. 113, 456), which bear strong resemblance to ose of Palenque On the whole it is not o much to say that, in spite of differences in style, the best means t judging what the temples and palaces of Mexico were like is to e gained from the actual ruins in Central America On the and, there are features in Central-American architecture which arcely appear in Mexican Thus at Uxmal there stands on a erraced mound the long narrow building known as the governor's ouse (Casa del Gobernador), 322 feet long, 39 feet wide, 26 feet gh, built of rubble stone and mortar faced with square blocks of one, the interior of the chambers rising into a sloping roof formed courses of stonework gradually overlapping in a "false arch" he same construction is seen in the buildings forming the sides of quadrangle and bearing the equally imaginary name of the nnery (Casa de Monjes), the resemblance of the interior of one its apartments to an Etruscan tomb has often been noticed (see rgusson, *History of Architecture*, vol ; Viollet-le-Duc, in ruary). Attempts to trace the architecture of Central America direct derivation from Old World types have not been successful, hile on the other hand its decoration shows proof of original inven on, especially in the imitations of woodwork which, as the above- entioned architects have pointed out, passed into sculptured rnament when the material of construction became stone instead wood Thus the architectural remains, though they fail actually solve the historical problem of the high culture of the nations und the Gulf of Mexico, throw much light on it when their idence is added to that of religion and customs Whether Mexican vilization was a barbaric copy of that which flourished in the now serted Central American cities, or whether the nations who built ese cities themselves raised to a higher level a civilization derived om Mexico, two things seem probable, first, that the civilizations Mexico and Central America were pervaded by a common influence religion, art, and custom, second, that this common element ows traces of the importation of Asiatic ideas into America.

Among works of reference on the ancient history and civilization of Mexico d Central America may be mentioned H H Bancroft, *The Native Races of the ific States of North America*, London 1875–6 (contains the most complete mmary, with references to original authorities); Brasseur de Bourbourg, *Histoire des Nations Civilisées du Mexique et de l'Amérique Centrale* Paris, 59–60), a valuable collection of materials, but the author's own views are mostly , *Historia de la Conquista de Mexico*, Clavigero *Storia Antica* a, 1780 forms the substance of earlier writers, such as Acosta, Botturini, &c.). For special topics Lord Kings- nough, *Antiquities of Mexico* London, 1831–48 (contains facsimiles and inter- tations of pictu- es, and prints the native chronicles of Ixtlilxochitl and Tezozo- oc, a priest of moc, &c.), A von Humboldt, *Vues des Cordillères, et Monumens de l'Amérique*, Paris, 1816 (Mexican civilization, ir writing, cal- ndar, &c.). Travels and descriptions of antiquities, &c. apers (Bra- ssbc C Nebel, *Viaje Pintoresco y Arqueologico sobre la epública de* ort 1839–4 de Waldeck, *Voyage Pittoresque et Archeo- logique dans la Province d'Yucatan*, Paris, 1838, and *Palenque et Autres Ruines*, aris, 1866, D Charnay *Cités et Ruines Américaines*, avec texte par Viollet le Duc, aris, 1863; J L ste, b ork, 1841; *Incidents of Yucatan*, New York, 1858, Brantz Mayer, *Mexico*, New York, 1-54 *Mexico, or Mexico and the Mexicans*, London, 861, &c (E B T)

II. THE REPUBLIC OF MEXICO.

Mexico, Aztec *Mexitli*[1] (Estados Unidos de Mexico), s a federal republic in North America, bounded N. by he United States (California, Arizona, and New Mexico), E. by Texas and the Gulf of Mexico, S. by Guatemala and British Honduras, where the boundary lines are still partly undetermined, W. by the Pacific Ocean. Lying between 33° and 15° N. lat. and 87° and 117° W. long., Mexico stretches about 1950 miles north-north-west and south south-east, with a mean breadth of 400 miles, varying from about 1000 in 26° N. to 130 at the narrowest part of the Tehuantepec isthmus. It has a coast-line of nearly 6000 miles, about 4200 on the Pacific and 1600 on the Atlantic. The seaboard is little varied either by deep inlets, bold headlands, broad estuaries, or large islands. On the west side are the vast Gulf of California in outline somewhat resembling the Red Sea, and so named by some of the early navigators, and the open Bay of Tehuantepec, besides the smaller inlets of Acapulco and San Blas, forming two of the finest harbours in the world and almost the only safe ones in the republic. On the east side the coast is mostly beset by lagoons and sand banks, with no good havens, Campêche, Vera Cruz, Tampico and Matamoras being all little better than open roadsteads exposed to the fierce "nortes," or north-easterly gales, that sweep the Gulf of Mexico for a great part of the year. Of headlands the most prominent are Capes S. Lucas and Palmas at the south extremity of Lower California, Corrientes south from San Blas, and Catoche in the north-east of Yucatan. Besides this peninsula, which projects north north east, the only other is that of Lower California which projects south-south-east parallel to the mainland. The islands are few in number, and all of insignificant size, the most noteworthy being Tiburon and Angel de la Guarda in the Gulf of California, the uninhabited Revillagigedo group in the Pacific, and Cozumel off the Yucatan coast. Mexico comprises altogether twenty-seven confederate states, one territory, and the Federal District, with areas, populations, and chief towns as under:[2]—

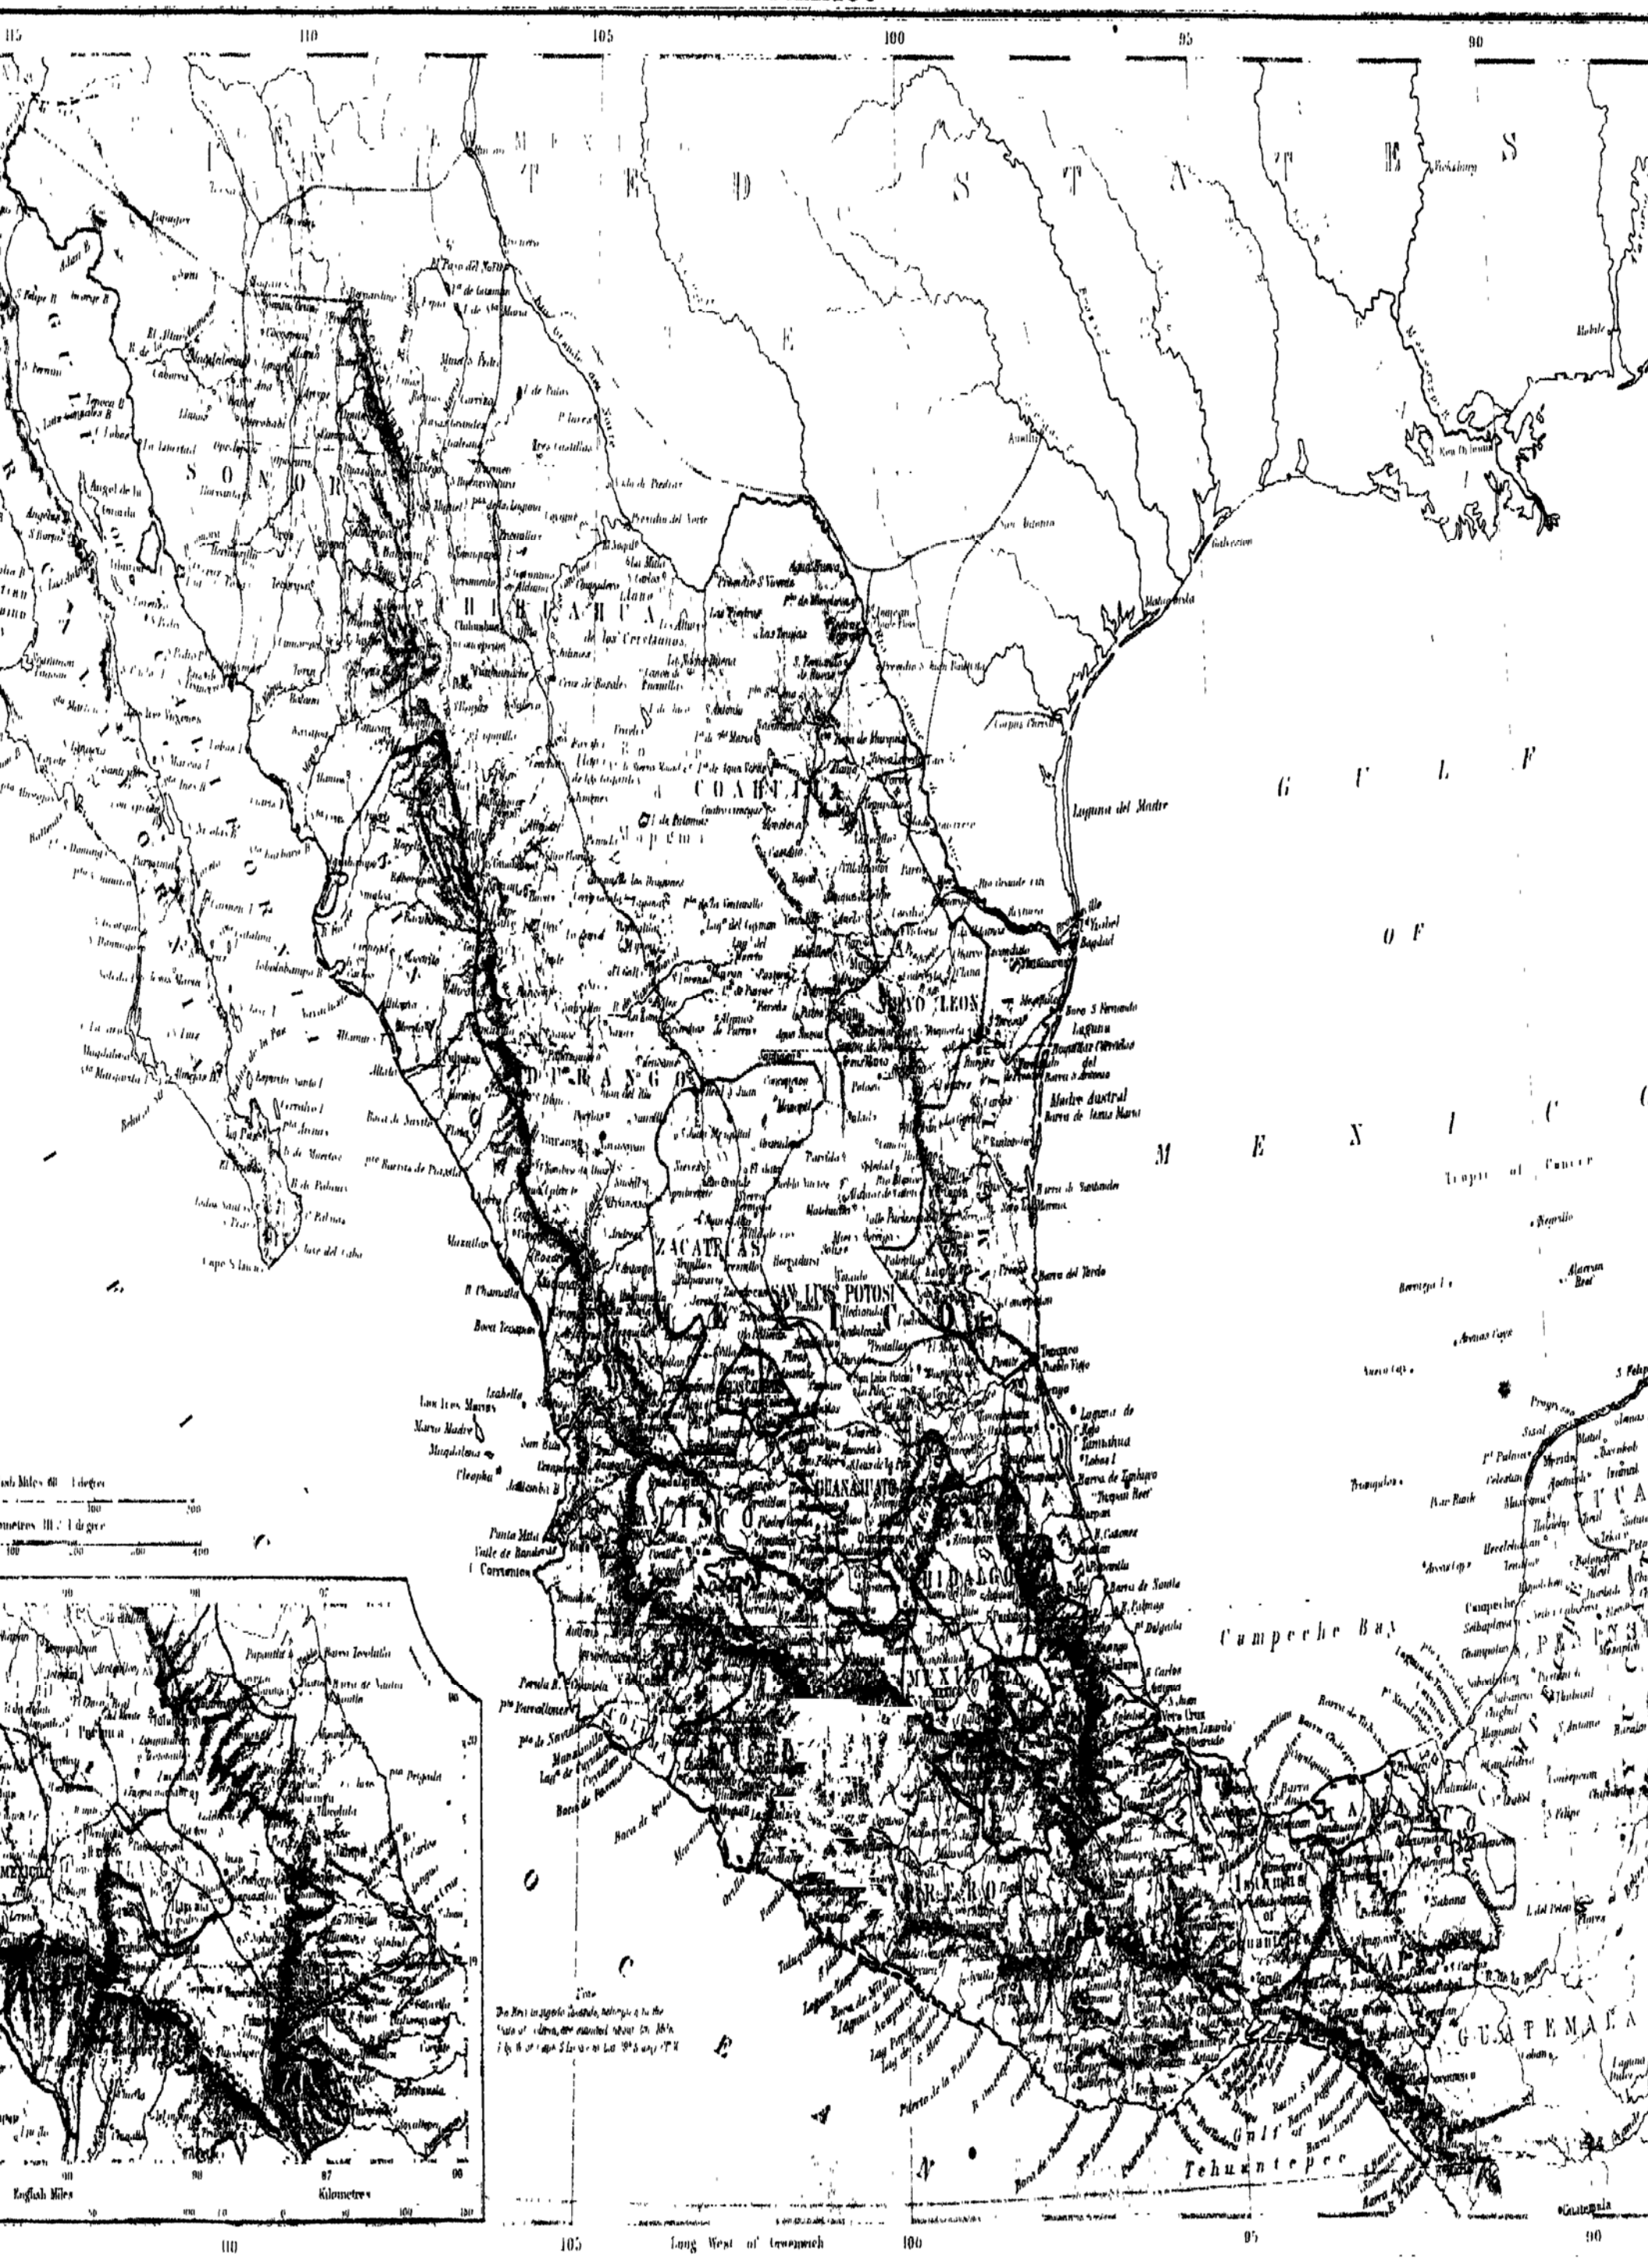
		Area in Square Miles	Population (1880)	Capital	Population (1877–80)
	Chihuahua	81,022	139,140		9,700
	Coahuila	165,295	180,758	Chihuahua	12,116
	Nuevo Leon	61,050	104,131	Saltillo	11,340
	Tamaulipas	11,363	194,861	Monterey	13,300
	Vera Cruz	28,659	144,747	Ciudad Victoria	7,800
	Tabasco	27,434	504,370	Jalapa	12,400
	Campeche	12,716	93,387	San Juan Bautista	6,800
	Yucatan	26,083	86,299	Campeche	15,190
	Sinaloa	32,658	285,384	Merida	32,000
	Jalisco			Culiacan	7,878
	Colima	18,967	994,900	Guadalajara	78,600
	Michoacan	2,393	65,827	Colima	24,572
	Guerrero	21,609	648,857	Morelia	20,400
	Oajaca	24,226	308,710	Bravos	5,800
	Chiapas	27,389	718,191	Oajaca	26,228
	Durango	16,769	219,735	San Cristobal	8,500
	Zacatecas	42,643	190,846	Durango	27,119
	Aguas Calientes	26,585	413,603	Zacatecas	32,000
	San Luis Potosi	2,216	140,130	Aguas Calientes	31,872
	Guanajuato	28,889	506,799	San Luis Potosi	34,300
	Queretaro	11,130	788,202	Guanajuat	56,112
	Hidalgo	3,429	179,915	Queretaro	27,560
	Mexico	4,480	434,090	Pachuca	12,500
	Morelos	9,598	696,058	Toluca	12,700
	Puebla	1,898	154,946	Cuernavaca	16,320
	Tlaxcala	11,761	704,372	Puebla	64,588
	Federal District	1,498	134,498	Tlaxcala	4,300
	Lower California (Territory)				241,110
			23,195	La Paz	2,396
		763,801	9,577,279		

Since the appearance of A. von Humboldt's classic work on *New Spain*, as Mexico was called in the colonial times, this region has continued to be regarded as forming a main link in the vast chain supposed to stretch across the entire length of the American continent from Cape

[1] In this, as in all other Aztec names, the *x* (or *j*) represents the English sound *sh*; hence *Mexitli* and *Mexico* should be properly pronounced *Meshitli*, *Meshico*. But they do not appear to have ever been so pronounced by the Spaniards, who naturally gave to the *x* its ordinary Spanish sound of the German *ch*.

[2] These figures, in the absence of scientific surveys and a trustworthy census, are necessarily more or less approximate The areas are those of Ripley and Dana, based on A. Garcia Cubas's *Carta geografica* (Mexico, 1874); the populations of the states and capitals are the estimates of Emiliano Busto in his *Estadistica de la Republica Mexicana* (Mexico, 1880). A writer in the *Times* of December 1882, estimates the whole population at 12,000,000, much too high a figure.

MEXICO



ENCYLLOPÆDIA BRITANNICA NINTH EDITION

Behring's Strait. But more recent research, and
y the surveys made by the French staff during the
operations between 1861 67,[1] have shown that
nd generalization must be abandoned. In remote
al epochs a marine channel seems to have flowed
the northern and southern sections of the New
at the isthmus of Panama, while Mexico itself
to be mainly a distinct geographical region
vely recent upheaval. Here there nowhere exists
nous mountain range, to which might properly be
the designation "Cordillera of the Andes," an
on which in any case is not current north of the
of Tehuantepec. Mexico forms, on the contrary,
able-land, somewhat in the shape of a cornucopia,
narrow end tapering to the south south-east, its
and concave sides facing the Pacific and Atlantic
vely, and with a general inclination northwards.
the so-called Cordilleras are merely the "cumbres"
pments of this plateau, which falls abruptly towards
ntic, and through a series of well-marked terraces
y lacustrine basins) towards the Pacific. Thus the
road from the capital runs in tolerably easy stages
vely through the Tetla (8000 feet), Mescala (5500),
lo (1800), and Peregrino (1600) valleys down to
ithin 10 miles of the seaport of San Blas. But
hern central plateau of Anahuac maintains its mean
n of 7000 to 8000 feet almost everywhere to within
0 miles of the Atlantic. Hence the railway opened
between Vera Cruz and the capital has had to be
by tremendously steep gradients to a height of
8000 feet within a total distance of 263 miles.[2]
neral but gradual northerly tilt of the table-land is
by the altitudes of the capital, Durango, Chihuahua,
o del Norte on the United States frontier, which
ectively 7600, 6630, 4600, and 3800 feet.
e same time the scarps rise in many places con-
y above the mean level of the plateau, which is
tersected and broken into a number of secondary
by several short cross ridges, generally following
nal direction from north north west to south south
The most continuous range is the Sierra Madre of
ific, which may be traced at a mean elevation of
,000 feet from Oajaca to Arizona, and which from
ajara to the northern frontier is crossed by no
route. Parallel to this is the Lower Californian
Sierra de la Giganta, 3000 feet), which, however,
ruptly eastwards, like the Atlantic escarpments.
alifornian peninsula seems to have been detached
e mainland when the general upheaval took place
roduced the vast chasm now flooded by the Gulf
fornia. Corresponding with the Sierra Madre of
ific on the west are the more interrupted eastern
f the central plateau, which sweep round the Gulf
ico as the Sierras Madres of Nuevo-Leon and
ipas at an elevation of about 6000 feet. These are
by the carriage routes from Tula to Tampico
pass 4820 feet), from Saltillo to Monterey (3400),
several other points.

ne central cross ridges the most important orogra
and historically is the Cordillera de Anahuac,[3] which surrounds the Mexican (Tenochtitlan) and Pueb
valleys, and which is supposed to culminate with Pop
catepetl (17,853 feet) and Ixtaccihuatl (15,705).[4] Bu
these giants belong to a different or rather a more recen
system of igneous upheaval, running from sea to se
between 18° 59′ and 19° 12′ N. in almost a straight li
east and west, consequently nearly at right angles to th
main axis of the central plateau. The line is clearl
marked by several extinct cones and by five active o
quiescent volcanoes, of which the highest is Popocatepet
lying south of the capital nearly midway between th
Pacific and Atlantic. East of this central point of th
system are Citlaltepetl, better known as the Peak of Orizab
(17,176 feet), 70 miles inland, and San Martin or Tuxt
(9708 feet) on the coast south of Vera Cruz, to whic
correspond on the west the recently upheaved Jorul
(4000 feet) in Michoacan, Colima (12,800) near the coa
in Jalisco, and the volcanic Revillagigedo group in th
Pacific. South of this line, and nearly parallel, are th
Sierras of Guerrero, and south of the Tehuantepec isthmu
those of Oajaca and Soconusco towards the Guatemal
frontier. In the same direction run the islands of Cub
and Hayti, which probably belong to the same Central
American system.

Mexico is thus physically connected through its olde
plateau formations with the North American table-land
and through its more recent volcanic upheavals with th
Central American igneous region. But as it advance
northwards this region loses in underground energy; hence
notwithstanding the remarkable upheaval of Jorullo i
1759, the Mexican cones show little signs of activity,[5] an
the land is now scarcely ever wasted by violent earth
quakes. Such phenomena are most frequent in the Pueb
valley; but, although often accompanied by the peculia
underground rumblings known as *bramidos*, they ar
seldom of a destructive character. The natives speak o
them rather as *temblores*, or "tremblings," than tru
terremotos.[6]

In a region where lofty ranges and plateau forma
tions with steep escarpments approach almost everywher
to within a few miles of the coast, little space is left fo
the development of large river basins. Most of th
streams are little more than mountain torrents rushin
impetuously from terrace to terrace seawards. Many als

---

[1] The results of these surveys are embodied in the *Carte du Mexique*, 3,000,000, published at Paris in 1873

[2] In the steepest parts the mean is 2·51 in 100, or 133¼ feet to the The exact elevation of the capital above the sea at Vera Cruz to be 7550 feet, or 80 more than Humboldt's estimate.

[3] The term *Anahuac*, meaning in Aztec "near the water," seems to en originally restricted to the central lacustrine basin of tlan. But when the Aztecs reached both oceans they extended Pacific coast between Tututepec and Guatemala (Anahuac- , and to the Atlantic coast between the Alvarado and rivers (Anahuac-Xicalanco). The original use of the word is still current amongst the natives as practically synonymous wi Central Mexico. As a strictly geographical expression it is vague and often incorrectly used by modern writer

[4] This elevation is based on the calculations of Humboldt, Glenn and Gerolt; but in 1857 Senntag assigned an extreme height of ov 17,000 feet to the highest peak of Ixtaccihuatl. Popocatepetl is usual supposed to be the highest point of North America, but the rece United States survey have transferred this honour to Mount Elias the Alaska coast, which appears to be certainly over 19,000 feet hig

[5] Popocatepetl emits smoke, whence its name, meaning in Azt "Smoking Mountain," from *popoca* "to smoke," and *tepetl* "mou tain." Since the conquest three eruptions have been reported (151 1539 1540); but the geological evidence seems to indicate th there has been no volcanic action for thousands of years. Orizab whose native name means "Star Mountain," has been quiescent sin 1566. Colima still frequently ejects ashes and smoke, but bo Jorullo and Tuxtla are quiescent, the last having been silent since t violent eruption of March 2, 1793. Even the Mal-pays, or bad l that formed Jorullo, has cooled down, and is now again clothed wi vegetation

[6] "It is noteworthy that the seismic waves flow normally along t indicated line from east to west, thereby confirming Humboldt's vie that under about 19° N. there is a deep rent in the earth's crus through which at different periods the underground fires have brok at various points between the Gulf of Mexico and the Revill gigedo group. "Only on the supposition that the volcanoes, whi are on the surface connected by a skeleton of volcanic rocks, are al united under the surface by a chain of volcanic elements in continu activity, may we account for the earthquakes which in the directi mentioned cause the American continent, from the Gulf of Mexico the Pacific Ocean, to oscillate at the same time" (Egloffstein, p. 37

flow through the profound rocky gorges or *barrancas*, as they are here called, which form a characteristic feature of the Mexican table lands.[1] On the east side some of these barrancas, here running mostly west and east, attain depths of 800 to 1000 feet in the mid-cretaceous limestones of that region; and even on the west coast the De Beltran Canon is flanked by sheer rocky walls over 500 feet high. Hence the rivers are almost useless for irrigation purposes, and available as means of communication only for short distances in their lower reaches, where they flow through the narrow alluvial strip of level coast lands to the sea. The Rio Grande del Norte, which is by far the largest, and which forms the entire line between Mexico and Texas, is navigable by large vessels only for a few miles above its port of Matamoras. The Rio Grande de Santiago, the largest on the Pacific side, is almost everywhere obstructed by falls and rapids. On this coast the next in importance is the Mercala, or Rio de las Balsas, which, like the Panuco, Alvarado, Coatzacoalcos, Grijalva, and Usumacinta flowing to the Gulf of Mexico, is subject to sudden rises during the rains.

At this season the waters which find no seaward outlet are collected in the depressions of the plateaus, where extensive tracts remain flooded for several months at a time. But these lacustrine basins of the Anahuac and Chihuahua table lands, standing at elevations of from 4000 to 7000 feet, are, by evaporation under semi-tropical suns, rapidly reduced to their normal level. The diminished size of the Anahuac lakes shows that since the conquest a steady process of desiccation has been going on, due probably to the reckless destruction of the upland forests by the European settler. None of these lakes are of great size except Lake Chapala, which is traversed by the Rio Grande de Santiago, and has a reputed area of about 1300 square miles. Amongst those of the plateau especially noteworthy for their magnificent scenery are Tezcuco and Chalco, in whose sparkling waters are reflected the surrounding volcanic peaks and extinct craters of the Anahuac table land, with a background formed by the Cordilleras, whose snowy summits rise here and there high above the dark pine forests of the lower slopes.

In the higher range the prevailing formations are granite, which seem also to form the foundation of the plateaus, above which rise the traps, basalts, mineral-bearing porphyries, and more recent lavas. Hence Lyell's theory that Mexico consisted originally of granitic ranges with intervening valleys subsequently filled up to the level of the plateaus by subterranean eruptions. Igneous rocks of every geologic epoch certainly to a large extent form the superstructure of the central plateau. But the Mexican table land seems to consist mainly of metamorphic formations, which have been partly upheaved, partly interpenetrated and overlaid by igneous masses of all epochs, and which are chiefly represented by shales, greywacke, greenstones, chlorite schists, and especially unfossiliferous limestone. All these formations are alike remarkable for the abundance and variety of their metalliferous ores, such as silver, silver-blende, copper, and gold. Gneiss and micaceous schists prevail in Oajaca and on all the southern slopes facing both oceans. But the highest ranges are formed mainly of plutonic and volcanic rocks, such as granites, syenites, diorites, mineral-bearing trachytes, basalts, porphyries, obsidian, pearlstone, sulphur, pumice, lavas, tufa, and other recent volcanic discharges. Obsidian (*itztli*) was the chief material formerly used by the natives in the manufacture of their cutting implements, as by the quarries of the Cerro de las Navajas ("Knife near Zimapan. Vast deposits of pumice and the sulphur are found at Huichapa and in many of the But immeasurably the most valuable rocks a argentiferous porphyries and schists of the central and in Sinaloa, unless they are destined to be rivalled auriferous deposits of Sonora.[2] Horizontal and s rocks, of extremely limited extent in the south, are developed in the northern states, and chalk becom prevalent towards the Rio Grande and Rio Gila To this chalk and to the sandstones are probabl referred the sandy plains which cover vast tracts i Mexico, stretching thence far into New Mexico and Here the Bolson de Mapimi, a vast rocky wi inhabited only by wild tribes, occupies a space of 50,000 square miles in Coahuila and parts of the su ing states.

None of the horizontal layers seem to be very ores, which are found mainly in the metamorphic, pa and hypogene rocks of Durango, Chihuahua, and th Apart from Sinaloa and Sonora, which are now k contain vast stores of the precious metals, nearly historical mines lie on the south central plateau a tions of from 5500 to 9500 feet. A line draw the capital to Guanajuato, and thence northw the mining town of Guadalupe y Calvo in Chi and southwards to Oajaca, thus cutting the ma of upheaval at an angle of 15°, will intersect proba richest known argentiferous region in the whol The central group of mines in the three mineral of Guanajuato, Zacatecas, and Catorze (San Luis which have yielded more than half of all the silver found in Mexico, lie between 21° and 24° 30′ N., w area of about 13,000 square miles. Here the Veta lode of Guanajuato alone produced £504,000 1556 and 1803, besides £10,000 of gold. This however, occurs chiefly, not on the plateau in ass with silver, but on the slopes facing the Paci apparently in greatest abundance in Sonora, auriferous region of New California. In recent ti half of the silver produced in the whole world h supplied by Mexico, and the total yield of the metals between 1537 and 1880 was as under:[3]—

	Gold.		
1537 to 1821	£14,000,000	£418,000,000	£432,0
1821 to 1880	10,000,000	180,000,000	190,0
Total . . .	£24,000,000	£598,000,000	£622,0

Of other minerals the most important are coppe in a pure state near the city of Guanajuato, and ated with gold in Chihuahua, Sonora, Guerrero,

[1] "Near the mountain ranges, fr which the water after heavy rains rushes down in innumerable forest streams, these ravines are filled with incredible rapidity as high as 30 feet, the torrent importing (*sic*) trees and bearing away rocks with a thundering noise and irresistible power" (Egloffstein, p. 22).

[2] "On the general character and distribution of the igneous f Von Egloffstein remarks "Intimate relations exist bet metalliferous and non metalliferous porphyries. The metalli phyry is less frequent, but constitutes the most important f bearing the precious metals, . . . embracing the rich lodes of Monte, Pachuca, Chico, Capula, and Santa Rosa, all of grea and magnitude. They further form the mineral districts Mineral del Monte, Oro, Huautla, &c., and part of the mountains of Zim Istapa-del Oro. The lodes found in this porphyry are cha by their magnitude and the consistency of the ores they cont The richest ores of native silver and sulphuret, chloride, an silver are found in the lodes of Real del-Monte, Pachuca, Santa Rosa . . The gold seems to exist in small particles in morphic porphyry mountains, whence it is carried by the rai valleys as the rocks become disintegrated" (pp. 6-8).

[3] *Times* correspondent, December 7, 1882. Guanajuato s still the greatest producer, yielding from £1,500,000 to £ yearly, although the great Valenciana mine is flooded, and of died opened only fifty-two are now worked (Geiger).

Michoacan, and elsewhere; iron in immense masses in Michoacan and Jalisco, and in Durango, where the Cerro del Mercado is a solid mountain of magnetic iron ore; lead associated with silver, especially in Oajaca; tin in Michoacan and Jalisco; sulphur in many craters; platinum recently found in Tlaxcala and Hidalgo; cinnabar also recently in Morelos and Guerrero; "steppe salt" in the sandy districts of the north; "bitter salt" at Tepeyac; coal in limited quantities at various points; bismuth in many parts; marble, alabaster, gypsum, and rock-salt in great abundance throughout the plateau and the sierras. In 1882 there were open altogether 569 mines:—541 silver, 14 gold, 4 copper, 4 lead, 3 salt, 2 coal, and 1 mercury.[1]

Intersected about midway by the Tropic of Cancer, and stretching across seventeen parallels of latitude, Mexico, from its position alone, necessarily enjoys a great diversity of climate. But from its peculiar configuration this feature is affected far more by the relief of the land than by its distance from pole or equator. This is especially true of the more fertile and populous section lying within the torrid zone, where three distinct climatic regions are distinguished, not according to their horizontal, but according to their vertical position. The temperature falling steadily with the elevation of the land, which here rises rapidly from sea-level to nearly 18,000 feet above the surrounding waters, the low-lying coast lands, up to about 3000 feet on the scarps and terraces of the central plateau, are comprised within the first zone of *tierras calientes*, or "hot lands." Within this zone are included all the sandy and marshy tracts fringing the Gulf of Mexico, the lower slopes facing eastwards and exposed to the hot and moist winds from the Caribbean Sea, and most of Yucatan and the Tehuantepec isthmus, besides the narrow strip between the uplands and the Pacific which broadens northwards along the east side of the Gulf of California. Here the mean temperature varies from 77° to 82° Fahr., seldom falling below 60°, but often rising to 105°, and in the sultry districts of Vera Cruz and Acapulco to 110°. The extreme north-western parts of this region come almost within the rainless zone, and the Californian peninsula itself is subject to excessive droughts, rendering it almost uninhabitable. But farther south the climate on both seaboards may be described as humid, hot, and extremely unhealthy, especially for Europeans. Yellow fever and black vomit are here endemic. But these scourges are at least compensated by a magnificent tropical vegetation and extensive virgin forests abounding in valuable timbers, dyewoods, and medicinal and other useful plants. Of the 114 species of trees and cabinet woods, 17 of oil-bearing plants, and over 60 of medicinal plants and dyewoods indigenous to Mexico, and often differing specifically from kindred varieties in Central and South America, by far the larger part are represented in the tierras calientes. Amongst the most important of these forest plants are mahogany, rosewood, copal, caucho (india-rubber), jalap, sarsaparilla, and Here also maize, supplying the staple food of the yields prodigious returns, multiplying from two to four hundred fold, and affording two, three, a four successive crops within the year. Rice, indigo, tobacco, and coffee all thrive well, while sugar, co banana, and several varieties of beans are largely cul The tobacco of Vera Cruz and Tabasco, the coffee of and the cocoa of Oajaca and Chiapas are of un excellence.

To the "hot lands" succeed in vertical posit *tierras templadas*, or "temperate lands," which c all the higher terraces and the central plateaus the between about 3000 and 8000 feet. With a mean t ture of from 62° to 70° Fahr., and oscillating such moderate extremes as 50° and 86°, this region one of the very finest climates on the globe. The and Anahuac table-lands are described by enth travellers as "terrestrial Edens," with a perennia symbolized by the evergreen oak, cedars, and analogous plants, which here attain their greatest tion. The transition from the lower zone is oft gradual; and, while endemic fevers cease altoge altitudes of 2700 and 2800 feet, the tropical flora many parts of the terrace lands, and even of the to heights of 4000 and 5000 feet.[2] A certain un is thus imparted to the Mexican landscape by t range of the maize, wheat, tobacco, vine, coffee, a plantations, as well as by the palms, evergreens, olive, orange, lemon, yucca, and an endless variet cactus family, one species of which forms hedges high on the Anahuac uplands. The central zone i whole drier than the southern lowlands, althou scarps facing seawards are often wrapped in the mists of the intercepted moisture-charged atm currents. The heaviest recorded rainfall (90 to 100 occurs in the healthy Huatusco district of Vera an altitude of 4380 feet.

In the highest zone of *tierras frias*, or "cold embracing all the highlands from about 8000 feet u the rainfall is five times less than on the tierras te Hence snow rests throughout the year only on most elevated peaks of Popocatepetl, Orizaba, Ne Toluca (15,000 feet), and Ixtaccihuatl. Chara both of the tierras frias and templadas is the (*Agave mexicana*), whose fruit is edible, and fermented juice has from time immemorial supp famous *pulque*, or national beverage of the M From the fibre of the henequen, an allied species duced the "Sisal hemp" of commerce, which has i years become the staple export of Yucatan.

Speaking generally, the four seasons are clearly north of 28° N. lat. only. South of that paral merge in the *estacion de las aguas*, or rainy seas May to October, and the *estacion seca*, or dry season prevails for the rest of the year. The rains g begin on the east coast, gradually moving westwa the Pacific the moist atmospheric currents are northwards, whence the striking contrast betw

[1] Lorenzo Castro, *Mexico in* 1882. According to this authority the total yield of the Mexican mines between 1537 and 1880 was £776,276,000, while another estimate based on a report of the Mexican mint gives it at £930,786,000. Of this a large amount has been coined in Mexico, where there were eleven mints at work in 1876, with a total annual yield of about £5,000,000. The total coinage since the conquest has been estimated as high as £600,000,000, not more than 5 per cent. of this being gold. With regard to coal, the existence of which in Mexico has been recently denied by Mr Bigelow in *Harper's Magazine*, official returns for 1882 give a list of over twenty places where it has been found, though nowhere as yet in large quantities. Petroleum also appears to be very abundant in several localities. Amongst other natural products mention should be made of amber, found on the Yucatan coast. Mineral springs are very numerous everywhere on the plateaus and terrace-lands. The most famous are El Peñon and N. Señora de Guadelupe near the capital, and Aguas Calientes farther north.

[2] On the Anahuac plateau, which stretches south of Popoc a mean height of 5000 to 5400 feet, "coffee, sugar, and indigo vated, and most of the tropical fruits grow luxuriantly" (E p. 17). The same authority gives the limits of vegetat region at 12,614 feet, and the snow line at 14,960 feet. He that "nothing is more surprising to the traveller than the v climate under this zone, which vary according to the different above the sea. In a few hours we descended from the cold the fir and the oak, on the heights of Ozumba, to a hot clim *caliente*, where we found the most luxuriant vegetation, that short time through successive changes of the most species of trees, plants, birds, insects" (p. 22).

ooded slopes of British Columbia and the treeless crests f the arid Lower Californian peninsula.

In its fauna no less than in its flora Mexico forms land of transition between North and Central America. n common with the north it has several varieties of the ear, the wolf, coyote, skunk, bison, squirrel, beaver, arten, otter, rattlesnake, heloderm,[1] mocking-bird, and any wild fowl; while its monkeys (five species), puma, guar, ocelot, sloth, tapir, alligators (two species), iguana, oa, scorpions, tarantulas, and numerous brilliantly coloured arrots, trogons, and humming-birds connect it with the outhern regions. Peculiar to Mexico, and distinguishing from most tropical and subtropical lands, are its song- ters, of which, besides the mocking-bird (*cenzontl*), as any as twenty species have been enumerated. The oasts are well supplied with fish and turtles, while the earl fisheries of the Gulf of California continue to be a ource of wealth to that otherwise unproductive territory, ielding in 1875 pearls to the value of £16,000, and 28,000 worth of shells. All the European domestic nimals thrive well, and vast herds of cattle, horses, and neep are found on the well stocked ranchos of the orthern states. Here some of the more prosperous readers own from twenty to thirty thousand head of xen, and next to the precious metals hides and cattle re among the chief articles of export.

But in the south stock breeding yields everywhere to griculture as the chief occupation of the people. Being rgely volcanic, the soil is here extremely fertile wherever ater can be had in sufficient quantities for irrigation urposes. Next to maize, which with beans and chilli rms the almost exclusive food of the Indians, the most portant crop is probably sugar, of which over 60 million ounds are annually produced in the state of Morelos alone. offee is extensively cultivated on the lower slopes, and ow exported in considerable quantities, especially to the nited States. The tobacco and cotton crops are yearly creasing in importance, while from the maguey is xtracted, besides pulque, a spirit called mezcal to the nnual value of about £750,000. The aborigines are rtly employed as free labourers on the plantations, and rtly hold small plots liable to a light Government x. The food crops thus raised were valued in 1873 £14,500,000, the agricultural produce at £30,000,000, nd the landed property at £85,000,000, but the last em was estimated by the minister of finance at fully ree times that sum. The value of arable freehold land as stated in 1882 to be from £1 to £3 per acre, accord- g to its proximity to or remoteness from rivers.

Of the industries strictly so called, those directly connected with gricultural interests have alone acquired any considerable develop- ent. Such are sugar refining, carried on on a vast scale, especi lly in Morelos; brewing and distilling, chiefly from maguey; paper- aking from various pulps and fibres; grist mills and saw-mills, specially in Puebla, Queretaro, Guadalajara, and Saltillo. A few on foundries have been at work for some years, and stout hand oven cotton and woollen fabrics are produced in many of the large owns. The rebozos (shawls) of Leon and Salvatierra have a wide epute, while Texcoco and Puebla are noted for their porcelain and lass ware. Among the petty industries are clay and rag figures, rtificial flowers, wooden toys, and gold filigree work, in the produc- ion of which the natives often display remarkable taste and skill.

But all these manufactured wares are solely intended to supply he local wants, so that the exports have hitherto been restricted lmost exclusively to the produce of the land and of the mines. f the former the chief items are coffee, Sisal hemp, tobacco, ides, lumber, cochineal, indigo, and other dyes, sarsaparilla, anilla, orchil, india rubber. But the precious metals still continue constitute fully two-thirds of all the exports, which in 1882 had total estimated value of about £6,000,000. In the same year an equal sum represented the imports, the leading items of which were cotton, linen, silk, and woollen goods, metals, hardware, machinery, and provisions. Although diplomatic and consular relations with Great Britain have been suspended since 1867, that country still continues to enjoy by far the largest share of the foreign trade, taking about £2,000,000 of the exports, and sending in return about two-thirds of all the imports, for 1882. Next in importance, in descending order, is the trade with the United States, France, Germany, Spain, and Columbia.

Probably four-fifths of the exchanges now pass through Vera Cruz, which, since the opening of the railway to the Anahuac plateau, has become the natural out-port of the capital and all the central states. It is connected by several lines of ocean steamers with Liverpool, Southampton, St Nazaire, and the Atlantic States of North America. On the Pacific seaboard, where the trade is largely in German hands, Acapulco and the other ports also enjoy regular steam communication with San Francisco and Panama. No accurate returns are available of the shipping; but the yearly arrivals in all the Mexican ports are stated to average about five thousand,—not more than one fifth under the national flag.

Till recently the means of internal locomotion were mainly C limited to the wretched bridle paths from the central plateau over m the sierras and terrace-lands down to a few points on both coasts, ti and to twenty four regular lines of diligences under one manage- ment. But since the completion of the line from Vera Cruz to the capital, with a branch to Puebla, the Mexican railway system has acquired a considerable development. The Inter-Oceanic line across the Tehuantepec isthmus is in progress; the Great Central Trunk line running northwards through Chihuahua will ere long effect a junction with the North-American net work; and at the end of 1882 there had been opened to traffic altogether 2219 miles. For that year the number of passengers carried was 8,250,000, and of mer- chandise 273 million tons, with net earnings £940,000, or £800 per mile. Still more developed is the telegraph system, which is now extended to all the state capitals, and through the Mexico-Mata- moras line to the United States and the rest of the world. The 8150 miles open in 1882 forwarded 750,000 messages, or in the proportion of 8 per 100 inhabitants.

For the same year the estimated revenue was £6,140,000, F and expenditure £6,300,000. The foreign debt is stated to be £19,600,000, and the internal about £10,000,000, or altogether at the rate of £3 per head of the population. Most of the foreign debt is owned in England, but the British claims had long been practically repudiated by the Mexican Government. At the end of 1882, however, a semi-official suggestion was made that a settle- ment might be effected by Mexico paying 1 per cent. on the capital for the first ten years, 2 for the second, and 3 there- after, the whole sum, amounting to £16,000,000, to be liquidated in fifty years.[2] The revenue is chiefly derived from the customs, and about £1,750,000 of the expenditure is absorbed by the army, the peace footing of which is 22,500 men of all arms. Beyond a few coastguard steamers maintained mainly for revenue purposes, there is no navy. An indication of financial improvement is afforded by the establishment in 1882 of the Mexican National Bank by a French company with a capital of £4,000,000. This bank is privileged to issue paper money up to £12,000,000, in return allow- ing the supreme executive to overdraw their account up to £2,000,000. A further symptom of revival is presented by the increasing business of the general post-office, which in 1880 forwarded 4,406,000 letters and packages through 873 offices.

Education also has made marked progress since the final I separation of church and state in 1857. In that year the old t university of Mexico, a purely ecclesiastical institution after the model of Salamanca and the Sorbonne, was abolished, or rather was re- placed by special schools of law, medicine, letters, agriculture, mines, sciences, fine arts, and commerce, and a military college. These, as well as numerous lower schools, including two hundred in the capital alone, are all maintained by the state, while national schools are supported by public grants in all the large towns, and higher institutions in the capitals of the several states. There are in all nearly five thousand public schools, besides establishments for the deaf and dumb, the blind, and juvenile delinquents, and numerous charitable foundations maintained by voluntary contri- butions.

Roman Catholicism, which under the Spanish rule was alone I tolerated, continued after the separation to be the state religion till 1857. Since then, while all churches enjoy equal protection, none are officially recognized. The great majority of the *Indios fideles*, mestizoes, and creoles still adhere at least outwardly to the Roman Church, which is administered by a hierarchy of three arch- bishops (Mexico, Morelia, and Guadalajara) and twelve bishops. But by the organic laws of 1856 and 1859 all ecclesiastical estates, at one time comprising over one-third of the soil, were nationalized,

[1] A specimen of this curious creature, the only known venomous ard (*Heloderma suspectum*), reached the London Zoological Gardens in 882; its habitat is the north of Mexico, and New Mexico, Arizona, nd Texas.

[2] This advance towards a settlement was put forward in the *Two Republics* of December 5, 1882, a Mexican journal which reflects the views of the Government on all matters of foreign policy.

he regular clergy suppressed, and their monasteries, together with ll other superfluous ecclesiastical structures, appropriated by the tate. During the last few years American Protestant missions ave claimed some partial success, and the so-called "Church of esus," an undenominational body of a somewhat original type, as found a number of adherents, especially on the Anahuac table-and. But the *Indios bravos*, or uncivilized aborigines, everywhere ollow the old spirit worship, while the Christianity of the Fideles little more than a cloak for the continuous practice of the former ztec heathenism. The pomp of the Roman ritual is supplemented y the feasts of the national worship, and the Pagan deities of the ld cult are still represented by the saints of the Roman calendar.[1]

Mexico constitutes at present a confederation of tates modelled on that of the North-American Union, nd administered according to the constitution of 1857 as mended in 1873–74. By popular suffrage are chosen the resident, the upper house (fifty-two members), and the upreme judiciary for four years, and the lower house (two undred and twenty-seven members) for two years. The enate, abolished in 1853, was restored 1874, and he chief justice is *ex officio* vice president. The federal tates, which are divided into a number of administrative districts, enjoy full autonomy in all local matters. The everal constitutions are modelled on that of the central government, and like it comprise three departments—egislative, executive, and judicial. Each state is repre sented in the federal congress in the proportion of one member for every 80,000 inhabitants, and in the federal senate by two members elected by suffrage in the local congress. All external affairs and questions of general interest are reserved for the central government. The constitution as now established thus represents in theory the complete overthrow of mediaevalism, and the absolute triumph of the new ideas which in the Old World are still in so many places struggling for the ascendency.

It is this struggle between privilege and popular rights that lends its human interest to the otherwise monotonous record of unresisted oppression and apparently aimless revolutions which characterize the early and the later periods of Mexican history, from the overthrow of the native rule down to the present day. The early or colonial period covers exactly three hundred years, from the death in 1521 of Guatemozin, last of the Aztec emperors, to the withdrawal of the last Spanish viceroy, Don Juan O'Donoju, in 1821. During these three centuries the attitude of the masses was one rather of sullen submission than of active resistance to grinding oppression. By the Spanish Government Mexico was looked on merely as a vast metalliferous region, to be jealously guarded against foreign intrusion and worked exclusively for the benefit of the crown. The natives were evangelized chiefly for the purpose of being employed as slaves above and below ground, and thus was introduced from the West Indies the system of *repartimientos*, or distribution of the aborigines on the plantations and in the mines. But, while this system proved fatal to the natives of Cuba and Hayti, where it had to be replaced by negro labour, the hardier populations of the Anahuac plateau successfully resisted its blighting influences. It proved in fact more disastrous to the oppressor than to the oppressed. In those days Spain was commonly compared to a sieve, never the richer for all the boundless wealth drawn from the New World. But the aborigines derived at least some advantage from contact and partial fusion with a people of superior culture. This fusion, which may be regarded as the chief outcome of the colonial administration, has contributed to the formation of the present exceedingly complex Mexican nationality, in which the Indian continues to be the predominating element. Taking the whole population at less than ten millions, its ethnical distribution appears to be at present as under :—

1. Full-blood Indians	5,000,000
2. Mestizoes (half-caste Indians and whites)	3,000,000
3. Creoles (whites of Spanish descent)	1,500,000
4. Gachupines[2] (Spaniards by birth)	50,000
5. Other Europeans and Americans	100,000
6. Full-blood negroes	10,000
7. Zambos or "Chinos" (Indo-Africans)	45,000
8. Mulattoes (Eurafricans)	5,000

Under the Spanish administration, which was marked on the surface by few stirring events, such as warlike expeditions, civil strife, or serious internal troubles, Mexico, or New Spain, formed a viceroyalty at one time stretching from the isthmus of Panama to Vancouver's Island. Antonio de Mendoza, appointed in 1535 after government by *audiencias* had proved a signal failure, was the first of sixty-four viceroys who ruled with almost autocratic power, but scarcely any of whom has left a name in history. Don Juan de Acuña (1722–31) is mentioned as having been the only native American among them, and Don Juan V. G. Pacheco (1789–94) had at least the merit of betraying some regard for the social welfare of his subjects. Under him a regular police, the lighting and draining of towns, and other municipal improvements were introduced.

But down to the early years of the present century all emoluments in church and state, most of the large plantations, of the mines, and of the commerce of the country, continued to be monopolized by the privileged gachupines, whom the creoles and mestizoes had already begun to regard as aliens. Hence the first reactionary movements, stimulated by Napoleon's deposition of King Ferdinand and arrest of the viceroy Hurrigaray in 1808, were aimed rather against odious class distinctions and the intolerable oppression of these aliens than against the abstract rights of the Spanish crown. The long smouldering spirit of discontent at last broke into open revolt in 1810 at Guanajuato, under the leadership of Don Miguel Hidalgo. After his defeat and execution in 1811, the struggle was continued by Morelos, who, like Hidalgo, was a priest, and shared his fate in 1815. But he had already called a national assembly at Chilpanzinco, and by this body Mexican independence was for the first time proclaimed in 1813. A guerilla warfare kept the national spirit alive till a fresh stimulus was given to it by the Spanish revolution of 1820. Under the leadership of the "Liberator" Iturbide, Mexican independence was again proclaimed on February 24, 1821, and the same year the capital was surrendered by O'Donoju, the last of the viceroys. But even after the revolt had thus been crowned with success a change of *personnel* rather than of system was contemplated; nor was Iturbide proclaimed emperor until the Mexican crown had been declined by a royal prince of Spain.

Almost simultaneously with this event the republican standard had been raised by Santa Anna at Vera Cruz (December 1822). Thus the nation had no sooner got rid of foreign rule than it became torn by internal dissension. But henceforth the struggle is not so much against the privileged classes as between Conservative and Liberal principles,—the former represented chiefly by the church and the superstitious populace, the latter by the more enlightened but not less unscrupulous sections of the community. From both the Indios Bravos, that is, about a third of the whole population, hold entirely aloof, and take advantage of the public disorders to continue their aggres-

[1] On the general state of religion in Mexico Bates well remarks:—"The educated classes conform to the outward ceremonies and ordinances of the church, while inwardly believing little or nothing of its dogmas. The lower grades of society are, on the other hand, steeped in the most grovelling superstition, intensified by many traditional Indian reminiscences. This section of the community yields a blind obedience to the clergy, notwithstanding the severe laws with which the Government has endeavoured to counteract the influence of the priests. Even so recently as 1874 a genuine case of witch-burning occurred in Mexico."—*Central America*, p. 34.

[2] From the Aztec *Gatzopin*, centaur; also known as *Chapetones*.

arfare against all alike.[1] Events now follow in quick sion, and as many as three hundred successful or ve revolutions are recorded during the brief but y life of Mexican national independence.[2] But amid onfusion of empires, republics, dictatorships, and ry usurpations, succeeding each other with bewilder- pidity, the thoughtful student will still detect a steady ess towards the ultimate triumph of those Liberal which lie at the base of true national freedom. A abulated summary of the more salient incidents in ventful struggle must here suffice :—

3. Mexican independence acknowledged by Spain ; regency under Iturbide, who (1822) is elected hereditary constitutional emperor ; in December Santa Anna proclaims the republic in Vera Cruz
4 Provisional Government ; Iturbide abdicates ; exiled, withdraws to London, but returning is shot (1824).
First Liberal constitution "Acta Constitutiva de la Federacion Mexicana," then comprising nineteen states and five territories, first president D. Felix Victoria, known as "Guadalupe Victoria."
0 Contested presidencies of Pedraza, Guerrero, and Bustamente
Reaction of the church party, constitution of 18[illegible] abolished, the confederate states fused in a consolidated republic under Santa Anna as president, but practically dictator
Texas refusing to submit secedes, defeats and captures Santa Anna
anta Anna returning resumes office.
Bravo's brief presidency followed by much anarchy.
1. Santa Anna's first dictatorship with two others.
Constitution restored with Santa Anna president, banished same year, he is succeeded by Canalizo.
Herrera president ; disastrous war with United States to recover Texas.
anta Anna again president.
Treaty of Guadalupe ; California and New Mexico ceded to United States.
anta Anna's second dictatorship; treaty of Mesilla (negotiated by Gadsden) ceding extensive territory to United States and reducing Mexico to its present limits ; great financial embarrassment ; "Plan of Ayutla" ; flight of Santa Anna followed by universal chaos.
Provisional Government under President Comonfort.
Constitutional convention ; radical reforms : rupture with Spain.
Liberal constitution of March 11 ; suspended December 1 ; Comonfort dictator ; the reaction supported by the church, large part of the army, and all Conservatives, opposed at Vera Cruz by Vice-president Benito Juarez at the head of the "Puros," or advanced Liberals ; the "War of Reform" begins, and lasts till 1860.
9 In the capital Comonfort is deposed by Zuloaga, who abdicates in favour of Miramon, general of the Conservative forces ; but, declining the presidency, Miramon restores Zuloaga ; British legation violated, in Vera Cruz the United States envoy MacLean acknowledges Juarez, who introduces further Liberal measures.
Capitulation of Guadalajara ; flight of Miramon from the capital, triumph of the Liberals.
Triumphal entry of Juarez into the capital ; further radical reforms, marriage declared a civil contract ; celibacy and ecclesiastical tribunals suppressed ; confiscation of church property valued at £75,000,000 and over a third of the soil ; final separation of church and state ; Spain, France, and England urge claims for losses of their subjects resident in Mexico ; convention of London ; intervention of the allies, who occupy Vera Cruz in December
England and Spain withdraw, their claims having been settled by negotiation, war continued by France.
4. The capital occupied by the French ; Louis Napoleon dreams of a universal fusion of the Latin races ; offers the Mexican imperial crown to the Austrian archduke Ferdinand Maximilian, who accepts, and arrives in June 1864.
After diverse issues the French withdraw ; Maximilian, abandoned to his fate, is captured and shot at Querétaro (June 19).

December 1882 a party of seventy five Mexicans and Americans assacred in the state of Chihuahua by a band of Bravos.
ween 1821 and 1868 the form of government was changed ten over fifty persons succeeded each other as presidents, dictators, erors; both emperors were shot, Iturbide in 1824, Maximilian and according to some calculations there occurred at least three *pronunciamientos*.

1867–69. Various pronunciamientos by Santa Anna and other
1871–72. Juarez president ; he dies in office July 1872 ; succ by his secretary Lerdo de Tejada.
1873–74. The Liberal constitution of 1857, which had been suspended (1858–60 and 1863–67), is now largely ame and continues to be henceforth the organic law of Me
1876. Tejada succeeded by Porfirio Diaz.
1880. Manuel Gonzalez, reigning president

Since 1869 the Liberal party has succeeded in preserving pe home and abroad, while establishing democratic institutions firm basis. A. v. Humboldt's gloomy anticipations[3] have not realized, and for the first time in its chequered history Mexic look forward with some confidence to a bright future. The p spot is the uncivilized Indian element. But with boundless n resources at its disposal, a wise administration may hope to come that difficulty, and gradually effect a complete fusion o antagonistic racial elements.

III. THE CITY OF MEXICO.

Mexico, the capital formerly of the Aztec empire a the Spanish colony of New Spain, and now of the repu state, and federal district of Mexico, stands on the Ana plateau, 7524 feet above sea-level, 2½ miles from the s west side of Lake Tezcuco (Texcoco), the lowest and la of six basins filling the deepest depression in the hill-enc Mexican valley. Situated in 19° 25′ 45″ N. lat. and 9 W. long., it is 173 miles by rail from Vera Cruz o Atlantic, 290 from Acapulco on the Pacific, 285 from Oa 863 from Matamoros on the United States frontier. M is the largest and finest city in Spanish America, for a square nearly 3 miles both ways, and laid out with pe regularity, all its six hundred streets and lanes runni right angles north to south and east to west, and cov within the walls an area of about 10 square miles, w population (in 1880) of 230,000. Most of the inhabi are pure-blood Indians or mestizoes ; but the foreig chiefly French, English, Germans, Americans, and Spani monopolize nearly all the trade, and as capitalists, ban merchants, and dealers enjoy an influence out o proportion to their numbers. A large portion of natives are mendicants or vagrants, and the disti criminal element (26,470 in 1878) is kept in order police force of 1320 men; yet in that year there we many as 5370 knife-attacks and 3250 robberies.

[3] Consulted shortly before his death as to the future prospe Mexico, with which his name was so intimately associated, Hum ventured to prophesy that "die Vereinigten Staaten werden es r reissen und dann selbst zerfallen."

well-paved, and gas-lit streets present a picturesque
nce with their quaint two- and three-storied stone
gaily painted in white, red, yellow, or green, and
ting everywhere with a background of rugged
or snowy peaks which, owing to the bright atmo
at this elevation, seem quite close, although really
0 miles distant. All the main thoroughfares con
n the central Plaza de Armas (Plaza Mayor, or
quare), which covers 14 acres, and is tastefully laid
h shady trees, garden plots, marble fountains, and
Here also are grouped most of the public buildings,
g above which is the cathedral, the largest and
mptuous church in America, which faces the north
the plaza on the site of the great pyramidal teocalli
ple of Huitzilopochtli, titular god of the Aztecs.
ifice, which was founded in 1573 and finished in
t a cost of £100,000 for the walls alone, forms a
ross 126 feet long and 203 wide, with two great
nd three aisles, twenty side chapels, and a magnifi
gh altar supported by marble columns, and sur
l by a tumbago balustrade with sixty two statues of
ne rich gold, silver, and copper alloy serving as
bra. The elaborately carved choir is also enclosed
bago railings made in Macao, weighing 26 tons, and
at about £300,000. In the interior the Doric style
s, Renaissance in the exterior, which is adorned by a
ne and two open towers 218 feet high. At the foot
left tower is placed the famous calendar stone, the
teresting relic of Aztec culture. The east side of
za is occupied by the old viceregal residence, now
tional Palace, with 675 feet frontage, containing
the Government offices (ministerial, cabinet, treasury),
y headquarters, archives, meteorological department
bservatory, and the spacious hall of ambassadors with
emarkable paintings by Miranda and native artists.
of the National Palace, and apparently forming
s of it, are the post-office and the national museum of
history and antiquities, with a priceless collection
xican remains. Close to the cathedral stands the
de Piedad, or national pawnshop, a useful institu-
ndowed in 1744 by Terreros with £75,000, and now
ing nearly £2,000,000 of accumulated funds.
the cathedral is the Palacio Municipal (city hall),
et by 122, rebuilt in 1792 at a cost of £30,000, and
aining the city and district offices, the corporation jail,
he lonja, or merchants' exchange. Around the
San Domingo are grouped the convent of that
said to contain vast treasures buried within its walls,
inquisition, now the school of medicine, and the
-house. In the same neighbourhood are the church
Jesuits and the school of arts, "an immense work-
ncluding iron and brass foundries, carriage and cart
ag, building and masonry, various branches of joinery
holstery work, and silk and cotton hand weaving"
lehurst). Other noteworthy buildings are the
al picture gallery of San Carlos, the finest in
ca, in which the Florentine and Flemish schools are
epresented, and which contains the famous Las
by Felix Parra; the national library of St Augustine,
ver 100,000 volumes, numerous MSS., and many rare
panish books; the mint, which since 1690 has
coinage, chiefly silver, to the amount of nearly
000,000; the Iturbide hotel, formerly the residence
emperor Iturbide; the Mineria, or school of mines,
ecture-rooms, laboratories, rich mineralogical and
ical specimens, and a fossil horse 3 feet high of the
cene period. Owing to the spongy nature of the
he Mineria and many other structures have settled
the perpendicular, thus often presenting irregular
and a rickety appearance. Among the twenty
scientific institutes mention should be made of the Geogr
phical and Statistical Society, whose meteorological depar
ment issues charts and maps of unsurpassed excellence.

Besides the chief market south of the National Palace there
three others, all well stocked with meat, fish, and especi
vegetables, fruits, and flowers grown mainly on the *chinampas*,
floating gardens of Lakes Chalco and Xochimilco. These garde
which were far more numerous in the Aztec times, are formed
placing layers of turf on the matted aquatic vegetable growths t
height of 2 or 3 feet above the water, and securing them by lo
willow poles driven through them to the bottom, where they ta
root. They form plots 100 to 200 feet long by 20 to 100 broad, a
are firm enough to support the huts of the cultivators. From t
still extant illuminated tribute rolls it appears that the Az
rulers derived a large share of the taxes from these gardens, wh
at that time also covered the brackish waters of Lake Tezcuco.

Before 1860 half of the city consisted of churches, convents, a
other ecclesiastical structures, most of which have been sequestra
and converted into libraries, stores, warehouses, and even stabl
or pulled down for civic improvements. Nevertheless there s
remain fourteen parish and thirty other churches, some of large s
with towers and domes, and their number has now been increas
by six Protestant churches including the Anglican cathedral
San Francisco Street. This is the leading thoroughfare, and
rivalled in splendour only by the new Cinco de Mayo Street runni
from the National Theatre to the cathedral.

The city is supplied by two monumental aqueducts, from Chap
tepec and the south-west, with good water at the rate of 44 gall
per day per inhabitant.

Its industries are varied but unimportant, consisting chiefly
gold and silver work, coarse glazed and unglazed pottery of pecul
form and ornamentation, paper, feather-work remarkable for its ta
and beautiful designs, toys, rosaries, crucifixes, religious pictur
lace, and some weaving.

Mexico enjoys an equable climate, with a temperature varying fr
70° to 50° F., but rendered unhealthy by the exhalations from
lakes and the bad drainage. The death-rate in 1876 was 59
1000, and 45 in 1878, pneumonia being most fatal (12 per cent. of
total). Standing at the lowest level of a lacustrine valley, 1
square miles in extent, and completely encircled by hills with
natural outlet, the city has always been subject to floodings fr
the overflow of the neighbouring freshwater lakes Zumpango
Xaltocan on the north and Xochimilco and Chalco on the sou
which, in the 17th century, laid the whole district under water
1607, and again for five years from 1629 to 1634. To remedy
evil the engineer Martinez began in 1607 the great cutting 13 m
long through the Nochistongo hill in order to draw off
discharge of Lake Zumpango, the highest in the valley, to the ri
Tula, a tributary of the Panuco, flowing to the Atlantic. This wo
which cost the lives of 70,000 natives, was completed in 1789; but
result was not satisfactory, and the city is still often flooded.

The chief public promenades are the Alameda, planted w
stately beeches; the Vega, skirted by the Vega Canal, and ador
with the colossal bust of Guatemozin, the last of the Aztec
perors; the Paseo de la Reforma, a fine avenue 3 miles long runn
south to the famous castle of Chapultepec, a place intimately as
ciated with the names both of Montezuma and Maximilian.
present castle, erected in 1785 by the viceroy Galvez on the site
Montezuma's palace, commands a superb view of the city and s
rounding district, and is approached by avenues of gigan
cypresses (*Cupressus disticha*) dating from Aztec times, growing
height of 120 feet, and measuring from 30 to 40 feet round the st
Other good roads with horse or steam trams lead to Tacubaya
the "Noche Triste" tree, where Cortes is traditionally supposed
have rested after the disastrous retreat from Mexico on the nigh
June 30, 1520, to the pleasant summer suburb of Tacubaya, and
the renowned shrine of Our Lady of Guadalupe, 3 miles to the eas
the border of Lake Tezcuco. Here stands the most famous chu
in Mexico, erected to commemorate the legendary apparitions of
Madonna to the Indian Juan Diego in December 1531, and
visited by thousands of pilgrims or sightseers.

Mexico dates either from the year 1325 or 1327, when the Az
after long wanderings over the plateau were directed by the or
to settle at this spot. For here had been witnessed the auspici
omen of an eagle perched on a nopal (cactus) and devouring a sna
Hence the original name of the city, Tenochtitlan (nopal o
stone), changed afterwards to Mexico in honour of the war
Mexitli. With the progress of Aztec culture the place rapidly
proved, and about 1450 the old mud and rush houses were repla
by solid stone structures erected partly on pile
Lake Tezcuco, and grouped round the central enclosure of the g
teocalli. The city had reached its highest splendour on the ar
of the Spaniards in 1519, when it comprised from 50,000 to 60,
houses, with perhaps 500,000 inhabitants, and seemed to Co
"like a thing of fairy creation rather than the work of mo
hands" (Prescott). It was at that time about 12 miles in circ

every where intersected by canals, and connected with the
d by six long and solidly constructed causeways, as is clearly
y the plan given in the edition of Cortes's letters published
nberg in 1524 (reproduced in vol. iv of H. H. Bancroft's
of the Pacific States, San Francisco, 1883, p. 280). After
st total destruction in November 1521, Cortes employed
0,000 natives in rebuilding it on the same site; but since
e lake seems to have considerably subsided, for although
square miles in extent it is very shallow, and has retired 2½
miles from the city. During the Spanish rule the chief ev

centre of civilizing influences for the surrounding semi-b
peoples.
(A. H

'ERBEER, GIACOMO (1791–1863), first known in
ny as Jakob Meyer Beer, was born at Berlin on
ber 5, 1791,[1] of a wealthy and talented Jewish
His father, Herz Beer, was a banker; his mother,
(*née* Wulf), was a woman of high intellectual
; and two of his brothers distinguished themselves
nomy and literature. He studied the pianoforte,
der Lauska, and afterwards under Lauska's master,
tz. When seven years old he played Mozart's Con-
D Minor in public, and at nine he was pronounced
t pianist in Berlin. For composition he was placed
Zelter, whose lessons were soon exchanged for those
hard Weber, then director of the Berlin opera, by
e was introduced to the Abbé Vogler. Struck by
liant talent, Vogler invited him to Darmstadt, and
) received him into his house, where he formed an
e friendship with Karl Maria von Weber, who,
his senior by eight years, shared the daily lessons
ived from the abbé in counterpoint, fugue, and
ore organ playing. At the end of two years the
uke appointed Meyerbeer composer to the court.
rly works, however, were far from successful, his
pera, *Jephtha's Gelübde*, failing lamentably at
adt in 1811, and his second, *Wirth und Gast*
k), at Vienna in 1814. These checks discouraged
cruelly that he feared he had mistaken his vocation.
heless, by advice of Salieri, he determined to study
ation in Italy, and then to form a new style. But
ce he was so captivated by the style of Rossini that,
ing all thought of originality, he produced a suc-
of seven Italian operas—*Romilda e Costanza*,
mide riconosciuta, *Edoardo e Cristina*, *Emma di*
go, *Margherita d'Anjou*, *L'Esule di Granata*, and *Il*
o in Egitto—which all achieved a success as brilliant
as unexpected. Against this act of treason to Ger-
t Weber protested most earnestly; and before long
eer himself grew tired of his defection, though the
of *Il Crociato* was so great that he was crowned
e stage. An invitation to Paris in 1826 led him
ew his position fairly and dispassionately, and he
ot conceal from himself the fact that he was wast
imitation powers which, rightly used, might make
e immortal. For several years after this he pro
nothing in public; but, in concert with Scribe, he
l the work which first made known the reality of his
ndent genius his first French opera, *Robert le*
This gorgeous drama was produced at the Grand
in 1831, and received with acclamation. It was the
its race, a grand romantic opera, abounding with
of startling interest, with situations more powerfully
ic than any that had been attempted either
erubini or Rossini, with mysterious horrors and
e pomp, and with ballet music such as had never
n heard, even in Paris. Its popularity exceeded all
s expectation; yet for five years after this signal
n Meyerbeer appeared before the public no more.
not doubt that his motive for this retirement was
ermination to produce something greater still; and
in some respects his next opera, *Les Huguenots*, rea
greater, though it fell short of the deep romance whi
dered *Robert le Diable* so incomparably captivating.
The first performance of *Les Huguenots* took p
1836. In gorgeous colouring, in depth of passion,
sistency of dramatic treatment, and in careful deli
of individual character, it is at least the equal of *R*
Diable. In two points only did its interest fall s
that inspired by the earlier work. Meyerbeer had
himself so great a master in his treatment of the
natural that one regretted the unavoidable omis
that powerful element in his second grand opera
more important still, the fifth act of *Les Huguenots*
arranged by the librettist as to render effective
treatment impossible. The substitution of a noisy fu
for a legitimate dramatic situation was fatal to the
pated climax. The music which accompanies this c
of the work is necessarily inferior to all that prec
The true interest of the drama culminates at the
the fourth act, when Raoul, leaping from the w
leaves Valentine fainting upon the ground. The sp
needs not to be told that the former will be shot de
moment he arrives in the street, or that the latt
mourn for him to the end of her days. Neither mu
nor dramatically does anything more remain to b
and therefore it is that those who quit the theatre
the curtain falls for the fourth time carry away wit
a far more perfect ideal than those who remain to t
After the production of *Les Huguenots* Meyerbee
retired from public view, and spent many years in t
paration of two of his greatest works—the greates
except the two we have already mentioned—*L'Af*
and *Le Prophète*. The libretti of both these opera
furnished by Scribe; and both were subjected to co
changes of detail before they satisfied the con
fastidious taste; in fact, the story of *L'Africai*
more than once entirely rewritten.
Meanwhile Meyerbeer accepted the appointm
kapellmeister to the king of Prussia, and spent
years at Berlin, where he produced *Ein Feldla*
Schlesien, a German opera, in which the ma
cantatrice Jenny Lind made her first appeara
Prussia, with unprecedented success. Here also h
posed, in 1846, the overture to his brother Michael's
Struensee. But his chief care at this period was be
upon the worthy presentation of the works of other
began by producing his dead friend Weber's *Eur*
with scrupulous attention to the composer's origina
With equal unselfishness he procured the accepta
Rienzi and *Der Fliegende Holländer*, the first two
of Richard Wagner, who, then languishing in pover
exile, would, but for him, have found it impossi
obtain a hearing in Berlin. With Jenny Lind as
donna and Meyerbeer as conductor, the opera flou
brilliantly in the Prussian capital; but the anxie
this thankless period materially shortened the con
life.
Meyerbeer produced *Le Prophète* at Paris in
and, if it did not at first create so great a sensation
Huguenots, this was simply because it needed to be

[1] Or, according to some accounts, 1794.

In 1854 he brought out *L'Étoile du Nord* at the Comique, and in 1859 *Le Pardon de Ploermel ah*). His last great work, *L'Africaine*, was in active tion at the Académie when, on the 23d of April he was seized with a sudden illness, of which he the 2d of May. *L'Africaine* was produced with attention to the composer's minutest wishes, on 8, 1865, and fully justified the expectation which en raised by his long and painstaking consideration details. Upon this, in conjunction with *Robert le Les Huguenots*, and *Le Prophète*, his fame now entirely rests.

beer's genius has been criticized with widely different re Mendelssohn thought his style exaggerated; Fétis thought of the most original geniuses of the age; Wagner calls miserable music-maker," and "a Jewish banker to whom red to compose operas." But the reality of his talent recognized throughout all Europe; and, in spite of the edged crudity of his system of phrasing, and the inequality too plainly observable even in his greatest works, his name so long as intensity of passion and power of dramatic t are regarded as indispensable characteristics of dramatic (W. S. R.)

ZIÈRES, a fortress of the first class, and the capital department of Ardennes, France, is 161 miles to the ast of Paris by railway, on a peninsula of the which almost entirely surrounds the town, and es it from its more important suburb, Charleville. rtifications, which, as well as the citadel, are the f Vauban, are pierced by four gates, giving access town, the streets of which are narrow and winding. rish church, erected in the 16th century, contains two ions in commemoration respectively of the raising siege of Mézières in 1521 and the marriage of s IX. with the daughter of the emperor Maximilian ich was celebrated at Mézières in 1570. The north uth portals, the glass of the windows, and the lofty gs of the church are worthy of remark. The hôtel contains several interesting pictures relating to the of the town. The iron industry, the only one of portance, is being gradually transferred to Charle- The population in 1881 was 6120.

led in the 9th century, Mézières was at first only a strong- onging to the bishops of Rheims, which afterwards became perty of the counts of Rethel. The town was increased by ve immigrations of the people of Liége, flying first from the Otho, and afterwards from Charles the Bold; and also by ons from the counts of Rethel. Its walls were built in the ntury, and in 1521 it was successfully defended by Bayard the imperialists. The anniversary of the deliverance of the still observed yearly on the 27th of September. The school ary engineering, since transferred successively to Metz and ebleau, was originally founded at Mézières.

ZÖ-TÚR,[1] a corporate town in the Cis-Tisian county -Nagy-Kun-Szolnok, Hungary, situated on the right f the Berettyó, and on the railway from Arad to k, in 47° 1′ N. lat., 20° 39′ E. long. It has Roman ic and Calvinist churches and schools, a judicial or the circuit, and the usual Government offices, but ast of few buildings of special interest. Horses, nd sheep are reared in great numbers on the wide- ing communal lands, which are productive also of , and especially wheat, rape-seed, and maize. On 1st December 1880 the population amounted to (10,265 males, 10,384 females), mostly Magyars ionality.

ZZOFANTI, Giuseppe (1774 1849), cardinal, whose ial linguistic acquirements have become proverbial, orn, September 17, 1774, at Bologna, where his followed the occupation of a carpenter. Educated t one of the "scuole pie," and afterwards at the episcopal seminary of his native city, he was ordai the priesthood in 1797, and in the same year becam fessor of Arabic in the university, but shortly after was deprived on account of his refusal to take the o allegiance to the Government of the Cisalpine Rep In 1803, however, he was appointed assistant librar the institute of Bologna, and soon afterwards was rein as professor of Oriental languages and of Greek. chair was suppressed by the viceroy in 1808, but rehabilitated on the restoration of Pius VII. in 181 continued to be held by Mezzofanti until his removal Bologna to Rome in 1831, when he received certain e astical appointments and the rank of monsignore. while his progress in the acquirement of language been rapid and untiring, and in 1833 he was appoin succeed Mai as chief keeper of the Vatican Library. promotion to the cardinalate, and the duties of direc studies in the Congregation of the Propaganda, follow 1838. He died at Rome, during the absence o pontifical court at Gaeta, on March 15, 1849.

Mezzofanti's peculiar talent, comparable in many respects of the numerous "calculating boys" who have been the won their contemporaries, was not combined with any exce measure of intellectual power, and accordingly produced n that has not perished with him. It seems to be well estal however, that he spoke with considerable fluency, and in som even with attention to dialectic peculiarities, some fifty o languages of the most widely separated families, besides h less perfect acquaintance with many others. See Manavit, *historique sur le Cardinal Mezzofanti*, Paris, 1854; and *Life of the Cardinal Mezzofanti*, London, 1857.

MEZZOTINT. See Engraving.

MIAUTSE. The Miautse or Meaou-tsze of so China are one of the aboriginal tribes of the co At one time they occupied a considerable portion rich and fertile lands which now form the central pr of the empire, but as the Chinese advanced south they were driven, like the Ainos in Japan and the in Britain, into the more inaccessible districts unti were compelled to seek refuge from the invaders mountain ranges, in the provinces of Yunnan, Kwei Kwang se, and Kwang tung, where they are found present day. This line of mountains extends for 400 miles, and, being in many parts high, steep, and r it forms a convenient shelter for them. As early reign of king Seuen (about 800 B.C.) we read of an e tion having been sent to drive them out of Hoo-na since that time they have been periodically attacked to punish them for misdeeds or to make them yi vineyards coveted by Chinese Ahabs. The last imp campaign against them was undertaken by the em K'een lung, who, having completely subjugated the E was desirous of bringing under his yoke these mo tribesmen. But the same success which had attend arms in the north did not follow them to the south first expedition was utterly defeated, and the gen command paid the penalty of discomfiture with hi The leader of a second expedition, having learned w by the fate of his predecessor, purchased the submis the Miautse by a large bribe. As soon as the unsus savages had been thus lulled into security a thir was set in motion against them. This time, being pared, they suffered a crushing defeat, and were co to purchase peace by swearing allegiance to their conq But, though the Chinese thus gained sovereignty ove they have since deemed it wise to content themselv but the shadow of authority. No real jurisdiction exercised over these hardy mountaineers. They are a to govern themselves on their own patriarchal system old men of each tribe manage the affairs of their j and command an obedience which would be utterly to the mandate of any mandarin. In figure the M

[1] ö is a Magyar word, signifying *Field*, prefixed to many agri- localities in Hungary.

en and women, are shorter and darker-complexioned
e Chinese, their faces also are rounder and their
s sharper. In disposition, too, they are very unlike
ivilized neighbours. They are brave, passionate,
ous, revengeful, and indifferent to cold and hunger;
re free and easy in their manners, and are as noisily
as the Chinese are grave and sedate.

are divided into between forty and fifty clans, each of which
guished by a name which is generally derived either from
ysical characteristic, or from some custom, or from the
of the clan, as, for example, "The Black Miau," "the
headed Miau," so named from their manner of dressing
ir, "the six-valley Miau," &c. Among these clans there
le difference of culture, one being in no way removed
ages, while others which have been brought under the influence
ese civilization show themselves apt and ready learners.
y of them, so far as is known, possess any written records.
on jin, or Goblin clan, are said to have books, which, though
now unable to read, they still regard with reverent awe.
ieroglyphic characters used in these books are, according to a
writer, "like knotted worms, and are utterly unintelligible."
los also are said to be a lettered clan, but for the most part
nese content themselves with conveying information and
g records by means of notched sticks. Their language as
heir ethnic characteristics proves them to be closely related to
ese, Annamese, Cambodians, and the inhabitants of Hainan;
hey form part of the race which is spread over the whole of
stern Indo-China. Their social customs are as widely
as their appearance is from those of the Chinese. The
titude is given to the youth of both sexes in the choice of
bands and wives. As among the hill tribes of Chittagong,
tion is commonly made on the mountain-side, where on moon
hts in the "leaping month" the young men and maidens
sing or to play at ball, or to dance round the "devil's stall"
Maypole), and to choose their partners for life. Among some
"couvade" is an established custom. Their funeral rites
rding to the districts, those living within reach of the influ
he Chinese having adopted their customs, while those more
till hang their dead in baskets from trees, or lay them in the
nd disinter them yearly to wash their bones. In dress they
of bright colours, and commonly wear loose but short
sometimes with and sometimes without trousers. The men
bans wound round their hair, which is raised above the
the shape of a spiral shell, and the women either don a
ap, or dress their hair in the shape of a ram's horn. For
ars the relations of the Miautse with the Chinese Govern
ve been generally of a peaceable nature, and in the *Peking*
ot April 1881 there was published a new system of
ent by which it is hoped that the incorporation of the
neers into the empire may become more real and complete

tion of judgment on the sins of Judah and Ephraim
a majestic exordium Jehovah Himself is represent
coming forth in the thunderstorm (comp. Amos i. 2)
His heavenly palace, and descending on the mounta
Palestine, at once as witness against His people, an
executer of judgment on their sins. Samaria is sent
to destruction for idolatry; and the blow extends to J
also, which participates in the same guilt (chap. i.).
while Samaria is summarily dismissed, the sin of Jud
analysed at length in chaps. ii. and iii., in which the pr
no longer deals with idolatry, but with the corrupti
society, and particularly of its leaders—the gra
aristocracy whose whole energies are concentrate
devouring the poor and depriving them of their
holdings, the unjust judges and priests who for
wrest the law in favour of the rich, the hireling
gluttonous prophets who make war against every
"that putteth not into their mouth," but are ever
with assurances of Jehovah's favour to their patron
wealthy and noble sinners that fatten on the flesh
poor. The prophet speaks with the strongest per
sympathy of the sufferings of the peasantry at the l
of their lords, and contemplates with stern satisfactio
approach of the destroyer who shall carry into exile
luxurious sons" of this race of petty tyrants (i. 16),
leave them none to stretch the measuring line on a fie
the congregation of Jehovah (ii. 5). The centre of co
tion is the capital, the city of Zion, grown great o
blood and wrongs of the provincials, the seat of the
princes, the corrupt judges and diviners. For their
he concludes, Zion shall be plowed as a field, Jeru
shall lie in ruins, and the temple hill return to j
(iii. 12).

The situation thus sketched receives its elucidation
the data supplied by the title (i. 1) and confirmed
rendered more precise by a remarkable passage in Jere
According to the title Micah flourished in the reig
Jotham, Ahaz, and Hezekiah; according to Jere
(xxvi. 18 *sq.*) the prophecy of the destruction of Jeru
just cited was spoken under Hezekiah, and bore fru
the repentance of king and people, by which the judg
was averted. The allusion beyond doubt is to Hezek
work of religious reformation (2 Kings xviii. 4 *sq.*).
hardly possible to separate this reformation from the
ence of Isaiah, which did not become practical in
conduct of the state till the crisis of Sennacherib's inva
and the conclusion that Hezekiah was not from the f
reforming king, which is forced on us by many passa
Isaiah, is confirmed by the prophecy of Micah, which,
Hezekiah's accession, still represents wickedness as s
in the high places of the kingdom. The internal disc
of the realm depicted by Micah are also prominen
Isaiah's prophecies; they were closely connected, not
with the foreign complications due to the approach o
Assyrians, but with the break-up of the old agr
system within Israel, and with the rapid and uncon
sated aggrandisement of the nobles during those
sperous years when the conquest of Edom by Am
and the occupation of the port of Elath by his
(2 Kings xiv. 7, 22) placed the lucrative trade bet
the Mediterranean and the Red Sea in the hand
the rulers of Judah. On the other hand the demo
tone which distinguishes Micah from Isaiah, and
announcement of the impending fall of the capital
deliverance of which from the Assyrian appears to I
as the necessary condition for the preservation of the s
a new and better kingdom), are explained by the fact
while Isaiah lived in the centre of affairs, Micah v
Morasthite or inhabitant of Moresheth Gath, a place
the Philistine frontier so unimportant as to be ment

Micah i. 14.[1] The provincial prophet sees the and the aristocracy entirely from the side of a man oppressed people, and foretells the utter ruin of both. s ruin does not present itself to him as involving ptivity or ruin of the nation as a whole; the gation of Jehovah remains in Judæa when the ors are cast out (ii. 5); Jehovah's words are still to them that walk uprightly; the glory of Israel is to take refuge in Adullam, as in the days when band of broken men was the true hope of the but there is no hint that it is banished from the Thus upon the prophecy of judgment we naturally to follow a prophecy of the redintegration of h's kingship in a better Israel, and this we find in 13 and in chaps. iv., v. Both passages, however, difficulties. The former seems to break the pointed t between ii. 11 and iii. 1, and is therefore regarded ld as an example of the false prophecies on which ked rulers trusted. The thought, however, is one to all true prophecy (comp. Hos. i. 11 [ii. 2], Isa. *sq.*, Zeph. iii. 11, Jer. xxxi. 8), and precisely in nce with chaps. iv., v., even in the details of expres d imagery.[2] It is indeed possible that these verses separate oracle of Micah, which did not originally n its present connexion. The sequence of thought s iv., v., on the other hand, is really difficult, and en rise to much complicated discussion.[3] There is a g feeling among scholars that iv. 11-13 stands in contradiction to iv. 9, 10, and indeed to iii. 12. st two passages agree in speaking of the capture of em, the first declares Zion inviolable, and its capture ossible profanation. Such a thought can hardly be s, even if we resort to the violent harmonistic process gining that two quite distinct sieges, separated by a l of the theocracy, are spoken of in consecutive An interpolation, however, in the spirit of such es as Ezek. xxxviii., xxxix., Joel iii. [iv.], Zech. xiv., conceivable in post-exilic times, and in connexion e growing impulse to seek a literal harmony of all ey on lines very different from the pre-exilic view xxvi., that predictions of evil may be averted by nce. Another difficulty lies in the words "and shalt come even to Babylon" in iv. 10. Micah tionably looked for the destruction of Jerusalem as well as of Samaria in the near future and by the As (i. 9), and this was the judgment which Hezekiah's ance averted. If these words, therefore, belong original context, they mark it as not from Micah but it is easy to see that they are really a later gloss prophetic thought is that the daughter (population) shall not be saved by her present rulers or de strength; she must come down from her bulwark dwell in the open field; there, and not within her ramparts, Jehovah will grant deliverance from her e This thought is in precise harmony with chaps. i. i equally characteristic is what follows in chap. v. opposition to present tyranny expresses itself in rec to the old popular ideal of the first simple Davidic k (iv. 8) to which he had already alluded in i. 15. old days shall return once more. Again guerilla (בת־גדוד) gather to meet the foe as they did in th of Philistine oppression. A new David, like him exploits in the district of Micah's home were still mouths of the common people, goes forth from Bet to feed the flock in the strength of Jehovah. The H Hebrew nations are once more united to their bret Israel (comp. Amos ix. 12, Isa. xvi. 1 *sq.*). The re of Jacob springs up in fresh vigour, inspiring terror the surrounding peoples, and there is no lack of captains to lead them to victory against the Assyri In the rejuvenescence of the nation the old stays oppressive kingship which began with Solomon, the holds, the fortified cities, the chariots and horses so to the life of ancient Israel, are no more known disappear together with the divinations, the sooth the idols, the *maṣṣēbôth* and *ashērîm* of the high Jehovah is king on Mount Zion, and no inventions come between Him and His people.

The elements of this picture, drawn so largely fr most cherished memories of the Judæans, could not produce a wide impression, especially when the inva Sennacherib, although it spared Jerusalem, fulfilled most striking way a great part of Micah's predic judgment. Of this we have evidence, not only in Je but in the political and religious ideas of the Deuteronomy. The picture of the right king (Deu 14 *sq.*) and the condemnation of the high-place follow the doctrine of Micah.

A difficulty still remains in the opening verses of Micah iv. 1-3 and Isa. ii. 2-4 are but slightly modified re of the same text, and as Isa. ii. is older than the prophecy while on the other hand Micah iv. 1 seems the natural co of the passage, it is common to suppose that both copy prophet. But the words have little connexion with the co Isaiah, and may be the quotation of a copyist suggested b On the other hand it has been urged that the passage belo later stage of prophetic thought than the 8th century B.C. is, however, no real difficulty in the idea that foreign nati seek law and arbitrament at the throne of the king of Zio the old prophecy Isa. xvi. 5, and the mention of the temp seat of Jehovah's sovereignty may be illustrated by Isa. vi., heavenly palace (Micah i. 3) at least pictured in the liken temple on Zion. At the same time the Jerusalem of Mi is the Jerusalem of David not of Solomon, the ideas of iv not reappear in chap. v., and the whole prophecy would p more consecutive and homogeneous if iv. 6 (where the dis the suffering are, according to chap. ii., the victims of dom of foreign oppression) followed directly on iii. 12.

The sixth chapter of Micah presents a very different from chaps. i.-v. Jehovah appears to plead with his peopl sins, but the sinners are no longer a careless and oppressi cracy buoyed up by deceptive assurances of Jehovah's help pheries of wine and strong drink; they are bowed do religion of terror, wearied with attempts to propitiate an a by countless offerings, and even by the sacrifice of the f Meantime the substance of true religion—justice, charit humble walk with God—is forgotten, fraud and deceit rei classes, the works of the house of Ahab are observed (w foreign gods). Jehovah's judgments are multiplied ag land, and the issue can be nothing else than its total desola

---

[1] Micah lived in the Shephela or Judæan lowland near the he country is clear from the local colouring of i. 10 *sq.*, where er of places in this quarter are mentioned together, and their layed upon in a way that could hardly have suggested itself ut a man of the district. The paronomasia makes the verses , and in i. 14 none of the ancient versions recognizes More-ath as a proper name. The word Morasthite (*Môrashti*) was e obscure to them; but this only gives greater weight to the al pronunciation with *ô* in the first syllable, which is as old XX., and goes against the view, taken by the Targum both on and on Jeremiah, and followed by some moderns (including , that Micah came from Maroshah. When Eusebius places ei near Eleutheropolis it is not likely that he is thinking of ah (Maresa), for he speaks of the former as a village and of the as a ruin 2 miles from Eleutheropolis. Jerome too in the *Paulæ* (*Ep.* cviii.), speaking as an eye-witness, distinguishes um, with the church of Micah's sepulchre, from Maresa. This was after the pretended miraculous discovery of the relics of in 385 A.D.; but the name of the village which then existed *in Mich.*) can hardly have been part of a pious fraud.

[2] figure of the shepherd gathering a scattered flock certainly ot presuppose a total captivity, as Stade (*Z. f. A.T.W.*, i. 161 nes.

[3] besides the commentaries, Noldeke in the *Bibel-lex.*, iv. 214; a by Oort and two by Kuenen in *Theol. Tijdsch.*, 1872; Well-Bleek, *Einleitung*, p. 426; Stade, *l.c.*, and *ibid.*, iii. 1 *sq.* oes so far as to make the whole of Micah iv., v. presuppose the nd to find still later additions in iv. 5-10., v. 5, 6 [v. 4, 5]. recht, *Theol. LZ.*, 1881, col. 443 *sq.*, rejects chap. iv. only. guments cannot be here cited at length, but they are tacitly view in what follows.

nks fit exactly the evil times of Manasseh as described in
XXI. Chap. VII. 1–6, in which the public and private cor-
of a hopeless age is bitterly bewailed. Micah belongs to
e context (comp. vol. XIII. p. 11b). Micah may very well
ed into Manasseh's reign but the title in i. 1 does not cover
ecy which certainly fell after Hezekiah's death, and the
s nothing in common with the earlier part of the book. It
lous present to regard the prophecy, with Ewald, as anony-
Ewald includes the whole of Isaiah xl.–lxvi. to one author.
ern however, remains with justice that the thread is
broken at vii. 6 and that verses 7–20 represent Zion as
taken before the heathen and her inhabitants as pining in
stress of captivity. The hope of Zion's future restora-
on in her patriarchs' and prophets' chastisement and
shown shall not be modified. His oath to the fathers, Israel
forgiven in the end and the heathen humbled. The faith
which breathes in this passage have the closest affinities
book of Lamentations and Isaiah xl.–lxvi.

e see that the book of Micah has suffered from redactors, it is also not
verbal inspiration which has left some parts very obscure. The LXX
ators suffered not for the present Hebrew but their text too was far
of commentators. Much that which deals most fully with the
of the text is found in Ewald (1868). The most elaborate

(W. R. S.)

HAEL (מִיכָאֵל, "who is like God?") appears in the
tament as a man's name, synonymous with Micaiah
ah. In the book of Daniel the same name is given
of the chief "princes" of the heavenly host, the
n archangel or "prince" of Israel (Dan. x. 13, 21, xii.
as such he naturally appears in Jewish theosophy
greatest of all angels, the first of the four who
d the throne of God (see GABRIEL). It is as
n angel of Israel, or of the church, the true Israel,
chael appears in Jude 9 and Rev. xii. 7. In the
n Church the festival of St Michael and All Angels
elmas) is celebrated on September 29th, it appears
grown out of a local celebration of the dedication
urch of St Michael either at Mount Garganus in
or at Rome, and was a great day by the beginning
9th century. The Greek Church dedicates
ber 8 to St Michael, St Gabriel, and All Angels.

HAEL, the name of several Byzantine emperors.

AEL I. (Rhangabé) was an obscure nobleman
d married Procopia, the daughter of Nicephorus I.,
n made master of the palace, his elevation to the
was due to a revolutionary movement against his
n-law Stauracius, who reigned only two months
he death of Nicephorus on the battlefield (812).
as the tool of the bigoted orthodox party in the
Michael diligently persecuted the Iconoclasts on
rthern and eastern frontiers of the empire, but
hile allowed the Bulgarians to ravage a great part
donia and Thrace, having at last taken the field
pring of 813, he was defeated near Versinikia, and
Armenian was saluted emperor in his stead in the
ne manner. Michael, after having been compelled
me a monk, was permitted thenceforward to live
ted in the island of Prote, where he died in 845.

AEL II. (The Stammerer), a native of Amorium
ygia, was of humble origin, and began life as a
soldier, but rose by his talents and assiduity to the
general. He was one of those who had favoured
tion to the throne of his old companion in arms
e Armenian in 813, but, detected in a conspiracy
the government of that emperor, had been sentenced
th in December 820, his partisans, however, suc-
in assassinating Leo on the morning of Christmas
nd called Michael from the prison to the throne.
ncipal features of his reign (820–829) were a pro-
struggle (of nearly three years) against his brother
, Thomas, who aimed at the throne, the conquest
e by the Saracens in 823, and the beginning of their
upon Sicily (827). Conciliatory on the whole
in his policy towards the image worshippers (hi
sympathies were iconoclastic), he incurred the wrath
monks by entering into a second marriage with Euph
daughter of Constantine VI., who had previously
the veil. He died in October 829, and was succee
Theophilus his son.

MICHAEL III. (The Drunkard) was the grand
Michael the Stammerer, and succeeded his father The
when only three years of age (842). Until his n
at the age of eighteen the affairs of the empir
managed by the empress regent his mother Theodo
education was shamefully neglected, and it was dur
period that Michael formed the disgraceful personal
which are indicated by his surname. In 861 M
together with his uncle Bardas, undertook an exp
against the Bulgarians, which resulted in the conver
the Bulgarian king, who thenceforth bore the C
name of Michael. The emperor had been less su
in the campaign which he led in person against C
Melitene in 860, but in 863 his uncle Petronas ga
important victory over the Saracens in Asia Minor
year 865 was marked by the first appearance of the R
in the Bosphorus. Michael was assassinated in his
in 867 by Basilius the Macedonian, whom he had ass
with himself in the empire in the previous year.

MICHAEL IV. (The Paphlagonian) owed his
tion to Zoe, daughter of Constantine IX., the
the Macedonian dynasty; this princess was mar
Romanus III., but becoming enamoured of Micha
chamberlain, she poisoned her husband and marr
attendant (1034). Michael, however, being of a
character and subject to epileptic fits, possessed the s
power only in name, and was a mere instrument
hands of his brother, John the Eunuch, who had be
minister both of Constantine and Romanus.
diplomacy was successful in keeping the Arabs
archipelago and Egypt quiet for some time, and
at last able to secure a victory for the imperial
Edessa in 1037. The attempt to recover Sicily
following year with the help of the Normans was l
sperous, and in 1040 the island wholly ceased t
Byzantine province. About the same time, the Bul
having overrun Macedonia and Thrace, and thre
Constantinople, the indolent and infirm emperor,
surprise alike of friends and foes, put himself at th

died, shortly after his triumph, on December 10, 10

MICHAEL V. (Calaphates or The Caulker),
and successor of the preceding, derived his surnam
his father Stephen, who had originally followed th
pation of a caulker of ships. He owed his el
(December 1041) to his uncle John, whom along w
he almost immediately banished; this led to a
tumult and his dethronement after a brief reign
months (April 1042). He lived for many years afte
in the quiet obscurity of a monastery.

MICHAEL VI. (The Warlike) was already an o
when chosen by the empress Theodora as her su
shortly before her death in 1056. His governme
feeble in the extreme, and he was at last compe
abdicate by Isaac Comnenus, who had defeated his a
Phrygia (August 1057). He also spent the rest of
in a monastery.

MICHAEL VII. (Ducas or Parapinaces) was the
son of Constantine XI. Ducas, by whom along w
brothers Andronicus I. and Constantine XII.
invested with the title of Augustus; this joint su
took place in 1067, but in 1071 it suited the policy
uncle Joannes Caesar to make Michael sole empero

osition Michael, whose "character was degraded, than ennobled, by the virtues of a monk and the g of a sophist,' was by no means fitted, and at two generals of the name of Nicephorus, surnamed ins and Botaniates, simultaneously rebelled against 1078; with hardly a struggle he resigned the purple ired into a monastery, where he afterwards received e of archbishop of Ephesus.

IAEL VIII. (Palaeologus), born in 1234, was the Andronicus Palaeologus Comnenus and Irene the granddaughter of Alexius Angelus, emperor stantinople. At an early age he rose to distinc nd ultimately became commander of the French aries in the employment of the emperors of A few days after the death of Theodore Lascaris 1259, Michael, by the assassination of Muzalon he is believed but not proved to have encouraged), ed to the guardianship, shared with the patriarch s, of the young emperor John Lascaris, then a lad eight years. Afterwards invested with the title of t," he was finally proclaimed joint emperor, and l alone at Nicaea on January 1, 1260. In the g year (July 1261) Constantinople fell into the of the Caesar Alexius Strategopulus, and Michael, got himself crowned anew in the church of St caused his boy colleague to be blinded and sent nishment. For this last act he was excommunicated nius, and the ban was not removed until six years rds (1268), on the accession of a new patriarch. In and 1261 respectively Michael, with the help of IV., concluded peace with Villehardouin, prince of and Michael, despot of Epirus, who had previously cited by the pope to attack him, the friendly inter- had been secured by a promise on the emperor's help forward the reunion of the Eastern and churches. In 1269 Charles of Sicily, aided by Thessaly, again made war with the alleged purpose ring Baldwin to the throne of Constantinople, and Michael so hard that ultimately, yielding to the nities of Gregory X., he caused the deputies of the church to attend the council of Lyons (1274) and accept the "filioque" and papal supremacy. The hus brought about between the two churches was, r, extremely distasteful to the Greeks, and the tion of his "schismatic" subjects to which the r was compelled to resort weakened his power so hat Martin IV. was tempted to enter into alliance harles of Anjou and the Venetians for the purpose nquering Constantinople. The invasion, however, nd Michael so far had his revenge in the "Sicilian s," which he helped to bring about. He died in in December 1282, and was succeeded by his son icus II.

IAEL IX. (Palaeologus) was the son of Andronicus l was associated with him on the throne from 1295, deceased him (1320).

HAELIS, JOHANN DAVID (1717-1791), one of st influential scholars and teachers of last century, d to a family which had the chief part in main- that solid discipline in Hebrew and the cognate ges which distinguished the university of Halle in iod of Pietism. Johann Heinrich Michaelis (1668 was the chief director of Francke's *Collegium ale Theologicum*, a practical school of Biblical and al philology then quite unique, and the author of an ted Hebrew Bible and various exegetical works of ion, especially the *Adnotationes uberiores in Hagio-*, 1720. In his chief publications J. H. Michaelis fellow-worker his sister's son Christian Benedict lis (1680-1764), the father of Johann David, who was likewise influential as professor at Halle, and sound scholar, especially in Syriac. J. D. Michae trained for academical life under his father's eye. was not then the best of universities; a narrow the spirit cramped all intellectual activity, and the eage cious youth, already distinguished by a love for readi a distaste for small pedantries, found much of the t wearisome enough. He acquired, however, a good ledge of the Latin classics, Greek, he tells us, was taught at all, and his knowledge of Greek literatu gained by his own reading in later years, learned his father could teach, and was influenced, especi philosophy, by Baumgarten, the link between t Pietism and Semler, while he cultivated his strong t history under Ludwig. In the winter-semester 1 he qualified as university lecturer. One of his d tions was a defence of the antiquity and divine au of the vowel points in Hebrew. His scholarsh moved in the old traditional lines in which no furth gress was possible, and he was also much exerci religious scruples, the conflict of an independent mi that submission to authority at the expense of encouraged by the type of Lutheranism in which been trained. A long visit to England in 1741 1 him out of the narrow groove of his earlier educatio passing through Holland he made the acquaintance great Schultens, whose influence on his philologica was not immediate, but became all powerful a few later. England offered to him no such commandi sonal influence, and he was not yet able to turn t the stores of the great libraries, but his personal strengthened by contact with a larger life, and hi logical views were turned aside from the pietistic c Michaelis never ceased to regard himself as ess orthodox, though he did not feel able fully to su the Lutheran articles, and more than once declined account to be professor of theology. But his acquired a distinctly rationalistic complexion, a orthodoxy of his Gottingen lectures and publicati dogmatic (delivered from a philosophical chair) is of washed out kind. His really useful work, however other directions; the change of his theological vi important because it relieved him from trammo hampered the free course of his development as a From England Michaelis went back to Halle; but himself out of place, and in 1745 gladly accep invitation to Gottingen as privat docent. In 17 became extraordinary, in 1750 ordinary, profe ssor, Gottingen he remained till his death in 1791. In t years of his new position Michaelis passed through a education. In the young and intellectually v Georgia Augusta he came under the powerful p influence of such men as Gesner and Haller. His i was active in many directions, universal learning was perhaps one of his foibles. Literature—mo well as ancient occupied his attention; one of hi was a translation of four parts of *Clarissa*; and tions of some of the then current English paraphr Biblical books manifested his sympathy with a which, if not very learned, attracted him by its fr His Oriental studies were reshaped by diligent pe the works of Schultens, for the Halle school, wit learning, had no conception of the principles on v fruitful connexion between Biblical and Oriental l can be established. His linguistic work indeed was hampered by the lack of MS material which is felt philological writings, *e.g.*, in his valuable *Supplem* the Hebrew lexicons (1784-92)[1]. He could not

MICHAUD, Joseph (1767–1839), French histo... and publicist, was born of an old family on June 19, 1... at Albens, Savoy. He was educated at Bourg-en-Bresse, ... afterwards engaged in literary work at Lyons, where ... events of 1792 first called into activity the dislike ... revolutionary principles which manifested itself throughout the rest of his life. In 1791 he went to Paris, where, without means, he took part in editing several royalist journals. In 1794 he started *Le Quotidienne*, for his connexion with which he was arrested after the 13th Vendémiaire, he succeeded in escaping his captors, but was sentenced to death *par contumace* by the military commission. Having resumed the editorship of his newspaper on the establishment of the Directory, he was again proscribed on the 18th of Fructidor, but at the close of two years returned to Paris when the consulate had superseded the Directory. His Bourbon sympathies led to a ... imprisonment in 1800, and on his release he for the time abandoned journalism, and began to write or edit books. Along with his brother and two colleagues he published in 1806 a *Biographie moderne, ou dictionnaire des hommes qui se sont fait un nom en Europe depuis* 1789, the earliest work of its kind, in 1808 the first volume of his *Histoire des Croisades* appeared, and in 1811 he originated the *Biographie Universelle*. In 1814 he resumed the editorship of the *Quotidienne*, and in the same year was elected Academician. In 1815 his brochure entitled *Histoire de quinze Semaines ou le dernier règne de Bonaparte* ... with extraordinary success, passing through twenty-six editions within a very short time. His political services were now rewarded with the cross of an officer in the Legion of Honour and the modest post of king's reader, of which last he was deprived in 1827 for having opposed Peyronnet's "Loi d'Amour" against the freedom of the press. In 1830–31 he travelled in Syria and Egypt for the purpose of collecting additional materials for the *Histoire des Croisades*; his correspondence with a fellow explorer, Poujoulat, consisting practically of discussions and elucidations of various important points in that work, was afterwards published (*Correspondance d'Orient*, 7 vols., 1832–35). The *Bibliothèque des Croisades*, in four volumes more, contained the "pièces justificatives" of the *History*. Michaud died on September 30, 1839, at Passy, where his home had been since 1832. His *Histoire des Croisades* was published in its final form in six volumes in 1841 under the editorship of his friend Poujoulat (9th ed., with appendix, by Huillard-Bréholles, 1856). Michaud, along with Poujoulat also edited and in part wrote *Nouvelle Collection des Mémoires pour servir à l'Histoire de France*, 32 vols., 1836–44. See Sainte-Beuve, *Causeries du Lundi*, vol. vii.

MICHAUX, André (1746–1802), a French botanist best known for his works on the flora of North America and as a botanical traveller. In 1779 he spent some time botanizing in England, and in 1780 he explored Auvergne, the Pyrenees, and the north of Spain. In 1782 he was sent by the French Government on a botanical mission to Persia. His journey began unfavourably, as he was robbed by Arabs of all his equipments except his books, but he gained influential support in Persia, having cured the shah of a dangerous illness. After two years he returned to France with a fine herbarium, and also introduced numerous Eastern plants into the botanic garden of France. In 1785 he was sent by the French Government to North America, and travelled through Canada, Nova Scotia, and the United States as far west as the Mississippi. The outbreak of the French Revolution deprived him of means to continue his work in America, and in 1796 he returned to France. He was shipwrecked and lost most of his collections on the voyage. In 1...

nt to Madagascar to investigate the flora of that and died there in 1802. His work as a botanist iefly done in the field, and he added largely to what eviously known of the botany of the East and of a. He also introduced many plants into Euro otanic gardens. He wrote two valuable works on American plants, the *Histoire des chenes de rique Septentrionale* (1801), with 36 plates, and the *Boreali Americana* (1803), 2 vols., with 51 plates.

'HAUX, François André (1770–1855), son of the ng, was, like his father, employed by the French ment to explore the forests of North America with to the introduction into France of trees valuable ir wood or other products. He was very success carrying out this object. He published in 1810–13 *oire des Arbres forestiers de l'Amérique Septentrionale*, ols., with 156 plates, a work full of information on haracters, uses, distribution, and other points of t in the various species. In 1817–19 a translation appeared under the title *North American Sylva*. o wrote a *Voyage à l'ouest des Monts Alléghanys*, besides articles in scientific magazines.

'HELANGELO (1475–1564). Michelangelo Buon best known simply as Michelangelo, the last and me of the great artists of Florence, was the son of ico Buonarroti, a poor gentleman of that city, and of e Francesca di Neri. Ludovico was barely able to the income of his estate, but made it his boast that never stooped to add to it by mercantile or mechani- suits. The favour of the Medici procured him em nt in some minor offices of state, and in the autumn d he was appointed resident magistrate of Caprese, Casentino, for a period of six months. Thither he ingly repaired with his family, and there, on March 5, his second son Michelagniolo or Michelangelo was Immediately afterwards the family returned to ce, and the child was put to nurse with a marble 's wife of Settignano. His mother's health had , it would seem, begun to fail; at all events in two years from this time, after she had borne her d two more sons, she died. While still a young Michelangelo determined in spite of his father's tion to be an artist. He had sucked in the passion, himself used to say, with his foster-mother's milk. a sharp struggle, his stubborn will overcame his s pride of gentility, and at thirteen he got himself d as a paid assistant in the workshop of the brothers ndaio. Domenico Ghirlandaio, bred a jeweller, had by this time the foremost painter of Florence. In rvice the young Michelangelo laid the foundations skill in fresco with which twenty years afterwards founded his detractors at Rome. He studied also, l the Florentine artists of that age, in the Brancacci , where the frescos of Masaccio, painted some sixty efore, still victoriously held their own; and here, in rel with an ill-conditioned fellow-student, Torrigiani, eived the blow of which his face bore the marks to ing day.

ugh Michelangelo's earliest studies were directed ls painting, he was by nature and predilection much inclined to sculpture. In that art he presently d encouragement and training under the eye of ustrious patron, Lorenzo dei Medici. On the nendation, it is said, of Ghirlandaio, he was trans- before the term of his apprenticeship as a painter xpired, to the school of sculpture established by zo in the Medici gardens. Here he could learn to himself against his great predecessor, Donatello, one se pupils was the director of the school, and to com- he works of that master and his Tuscan contemporaries with the antiques collected for the instruction of the sc Here, too, he could listen to discourses on Platonic steep himself in the doctrines of an enthusiastic philo which sought to reconcile with Christian faith the lo the doctrines of the Academy. Michelangelo remai Christian Platonist to the end of his days; he w from his youth up a devoted student of Dante's powers of mind and hand soon attracted attention secured him the regard and favour of his patron, in spite of his rugged, unsociable exterior, and of a temper at best was but a half-smothered volcano.

Michelangelo had been attached to the school and hold of the Medici for barely three years when, in his great patron Lorenzo died. Lorenzo's son Pie Medici inherited the position, but not the qualities, father; Florence soon chafed under his authority towards the autumn of 1494 it became apparen disaster was impending over him and his adh Michelangelo was constitutionally subject to dar sudden presentiments: one such seized him now without awaiting the popular outbreak which soon fol he took horse with two companions and fled to Bo There, being now in his twentieth year, he was re civ kindness by a member of the Aldovrandi family, a his commission executed two figures of saints, and an angel, for the shrine of St Dominic in the church Petronius. After about a year, work at Bologna f and his name having been included in his absence list of artists appointed to provide a new hall of as for the Great Council of Florence, Michelangelo re home. The strange theocracy established by Savo was now in force, and the whole character of civic Florence was for the time being changed. But Michel was not left without employment. He found a fri another Lorenzo, the son of Pierfrancesco dei Med whom he at this time executed a statue of the boy St Having also carved a recumbent Cupid in imitation antique, it was suggested to him by the same that it should be so tinted and treated as to look real antique, and sold accordingly. Without men the price he put upon the work, Michelangelo for a ment lent himself to the counterfeit, and the piece wa actually sold for a large sum to a Roman collecto cardinal San Giorgio, as a genuine work of antiquity dealer appropriating the profits. When present cardinal discovered the fraud, he caused the dea refund; but as to Michelangelo himself, it was repre to the young sculptor that if he went to Rome, the ar who had just involuntarily paid so high a tribute skill would certainly befriend him. He set forth ingly, and arrived at Rome for the first time at the June 1496. Such hopes as he may have entertai countenance from the cardinal San Giorgio were d dispelled. Neither did the banished Piero dei Medi also was now living at Rome, do anything to hel On the other hand Michelangelo won the favou Roman nobleman, Jacopo Galli, and through him French cardinal Jean de Villiers de la Grolaie, ab St Denis. From the former he received a commis a Cupid and a Bacchus, from the latter for a P Mary lamenting over the body of Christ,—works of probably all three, the last two certainly, are preser

helangelo had not been long in Rome before Pope devised fit employment for him. That capacious eadstrong spirit, on fire with great enterprises, had ved the idea of a sepulchral monument to commemorate his glory when he should be dead, and to be ed according to his own plans while he was still He entrusted this congenial task to Michelangelo. esign being approved, the artist spent the winter of 6 at the quarries of Carrara, superintending the ation and shipment of the necessary marbles. In the he returned to Rome, and when the marbles arrived with all his energy at the preparations for the work. while the pope followed their progress eagerly, as all kindness to the young sculptor. But presently isposition changed. In Michelangelo's absence an who was no friend of his, Bramante of Urbino, had elected by Julius to carry out a new architectural e, commensurate with the usual vastness of his conns, namely the rebuilding of St Peter's church. To fluence and the malice of Bramante Michelangelo attributed the unwelcome invitation he now received interrupt the great work of sculpture which he had begun, in order to decorate the Sixtine chapel with fr Soon, however, schemes of war and conquest interpo divert the thoughts of Julius, not from the progress own monument merely, but from artistic enter altogether. One day Michelangelo heard him say at to his jeweller that he meant to spend no more mon pebbles either small or great. To add to the artist's confiture, when he went to apply in person for payment due, he was first put off from day to day, and a actually with scant courtesy dismissed. At this ni mood got the mastery of him. Convinced that n employment only but his life was threatened, he sad took horse and left Rome, and before the messeng the pope could overtake him was safe on Flore territory. Michelangelo's flight took place in April Once among his own people, he turned a deaf ear overtures made from Rome for his return, and throughout the summer at Florence, how occupied v not distinctly informed, but apparently, among things, on the continuation of his great battle cartoon

During the same summer Julius planned and exe the victorious military campaign which ended unopposed entry at the head of his army into Bo Thither, under strict safe-conduct and promises of re favour, Michelangelo was at last prevailed on to h himself. Julius received the truant artist kindly, as i between these two volcanic natures there existed a m affinity, and ordered of him his own colossal liken bronze, to be set up, as a symbol of his conq authority, over the principal entrance of the church Petronius. For the next fifteen months Michel devoted his whole strength to this new task. The at which he undertook it left him, as it turned out, any margin to subsist on. Moreover, in the technic of metal casting he was inexperienced, and an ass whom he had summoned from Florence proved m dinate and had to be dismissed. Nevertheless his prevailed over every hardship and difficulty, and o 21st of February 1508 the majestic bronze colos the seated pope, robed and mitred, with one hand gr the keys and the other extended in a gesture of be tion and command, was duly raised to its station ov church porch. Three years later it was destroyed revolution. The people of Bologna rose against authority of Julius; his delegates and partisans wer out, and his effigy hurled from its place. The wo Michelangelo, after being trailed in derision throug streets, was broken up and its fragments cast int furnace.

Meanwhile the artist himself, as soon as his wor done, had followed his reconciled master back to The task that here awaited him, however, was after the resumption of the papal monument, but the exe of the series of paintings in the Sixtine chapel whi been mooted before his departure. Painting, he averred, was not his business; and he entered misgiving and reluctance upon his new undert Destiny, however, so ruled that the work thus thrust him remains his chief title to glory. His history is indomitable will and almost superhuman energy, yet that hardly ever had its way, and of energy contr at war with circumstance. The only work which in life he was able to complete as he had conceived this of the decoration of the Sixtine ceiling. The had at first proposed a scheme including figures o twelve apostles only. Michelangelo would be conten nought so meagre, and furnished instead a design of hundred figures, embodying all the history of creatio

first patriarchs, with accessory personages of prophets
oyls dreaming on the new dispensation to come, and,
ition, those of the forefathers of Christ. The whole
be enclosed and divided by an elaborate framework
ted architecture, with a multitude of nameless human
supporting its several members or reposing among
shape mediating, as it were, between the features
inanimate framework and those of the great dramatic
ophetic scenes themselves. Michelangelo's plan was
ed by the pope, and by May 1508 his preparations
execution were made. Later in the same year he
oned a number of assistant painters from Florence,
d in the tradition of the earlier Florentine school,
were unable, it seems, to interpret Michelangelo's
s in fresco either with sufficient freedom or sufficient
unity of style to satisfy him. At any rate he soon
ed them, and carried out the remainder of his
l task alone, except for the necessary amount of
mechanical and subordinate help. The physical
ons of prolonged work, face upwards, upon this vast
e of ceiling were adverse and trying in the extreme.
ter four and a half years of toil the task was
hed. Michelangelo had during its progress been
d alike by delays of payment and by hostile intrigue.
solute need of funds for the furtherance of the
king had even constrained him at one moment to
off work, and pursue his inconsiderate master as far
gna. Ill wishers at the same time kept casting
on his capacity, and vaunting the superior powers
hael. That gentle spirit would by nature have been
's enemy, but unluckily Michelangelo's moody, self-
rated temper prevented the two artists being on
f amity such as might have stopped the mouths of
f makers. Once during the progress of his task
angelo was compelled to remove a portion of the
ing and exhibit what had been so far done, when
et alike upon friends and detractors was overwhelm
Still more complete was his triumph when, late in
tumn of 1512, the whole of his vast achievement
closed to view.

ain field of the Sixtine ceiling is divided into four larger
ng with five smaller fields. The following is the order of the

his own manner.

The Sixtine chapel was no sooner complete
Michelangelo resumed work upon the marbles f
monument of Julius. But four months only had
when Julius died. His heirs immediately entered
summer of 1513) into a new contract with Miche
for the execution of the monument on a reduce
What the precise nature and extent of the original
had been we do not know, but the new one was ex
and magnificent enough. It was to consist of a
quadrilateral structure, two courses high, projectin
the church wall, and decorated on its three unattache
with statues. On the upper course was to be pla
colossal recumbent figure of the pope under a
and beside it mourning angels, with prophet
allegoric personages at the angles, sixteen figu
all. The lower course was to be enriched with
four figures in niches and on projecting pedesta
the niches, Victories trampling on conquered Pro
in the pedestals, Arts and Sciences in bondage
entire work was to be completed in nine years
During the next three years, it would seem, Miche
brought to completion three at least of the p
figures, and they are among the most famous of a
ing works of the sculptor's art,— namely, the Mos
in the church of S. Pietro in Vincoli at Rome a
two "Slaves" at the Louvre.

The Moses, originally intended for one of the angles of t
course, is now placed at the level of the eye, in the centr
principal face of the monument as it was at last finishe
deplorably reduced and altered scale, by Michelangelo
assistants in his old age. The prophet, heavily bearded and
with only his right arm bare, sits with his left foot draw
his head raised and turned to the left with an expressio
dignation and menace, his left hand laid on his lap and h
grasping the tables of the law. The work, except in on
places, is of the utmost finish, and the statue looks like on
prophets of the Sixtine ceiling done in marble. The "Sl
the Louvre are youthful male figures of equally perfect ex
nude but for the band which passes over the breast of one
right leg of the other. One, with his left hand raised to
and his right pressed to his bosom, and his eyes almost
seems succumbing to the agonies of death; the other, with
bound behind his back, looks upward still hopelessly str
There is reason to believe that all three of these figures were
between 1513 and 1516. The beginnings of other figures o
intended for the same monument are to be found at Florenc
they were no doubt made and then abandoned some years
viz., four rudely blocked figures of slaves or prisoners, in
of the Boboli gardens, and the so-called Victory in the
Museum, an unfinished group of a combatant kneeling
crushing to death a fallen enemy; with these may be as
a wax model known as Hercules and Cacus in the Sout
sington Museum, and the figure of a crouching man at St
burg.

By this time (1516) Michelangelo's evil star wa
in the ascendant. Julius II. had been succeeded
papal throne by a Medici under the title of Leo X
Medici, too, had about the same time by force and
re-established their sway in Florence, overthrowing t
institutions that had prevailed there since the
Savonarola. Now on the one hand this family w
hereditary friends and patrons of Michelangelo;
other hand he was a patriotic son of republican Fl
so that henceforward his personal allegiance a
political sympathies were destined to be at conflict.

f his art, as has been thought, the pain and per- of this conflict have cast their shadow. For the the consequence to him of the rise to power of the was a fresh interruption of his cherished work on b of Julius. Leo X. and his kinsmen insisted that ngelo, regardless of all other engagements, must and carry out a great new scheme for the enrich- f their own family church of San Lorenzo in e. The heirs of Julius on their part showed an odating temper, and at the request of Leo allowed ree years'-old contract to be cancelled in favour of , whereby the scale and sculptured decorations of ian monument were again to be reduced by nearly Unwillingly Michelangelo accepted the new com thus thrust upon him for the church façade at e; but, having once accepted it, he produced a of combined sculpture and architecture as splendid bitious in its way as had been that for the monu- Julius. In the summer of 1516 he left Rome for to superintend the excavation of the marbles. elangelo was now in his forty second year. Though han half his life was yet to come, yet its best ad, as it proved, been spent. All the hindrances e had encountered hitherto were as nothing to hich began to beset him now. For the supply of ls for the façade of San Lorenzo he had set a firm ns to work, and had himself, it seems, entered into f partnership with them, at Carrara, where he knew rries well, and where the industry was hereditary ll understood. When all was well in progress there is own eye, reasons of state induced the Medici Florentine magistracy to bid him resort instead ain new quarries at Pietrasanta, near Serravalle in itory of Florence. Hither, to the disgust of his old t Carrara and to his own, Michelangelo accordingly ransfer the scene of his labours. Presently he found so impeded and enraged by the mechanical difficulties g and transporting the marbles, and by the disloyalty ompetence of those with whom he had to deal, that fain to throw up the commission altogether. The ts for the façade of San Lorenzo were rescinded in 1518, and the whole magnificent scheme came to . Michelangelo then returned to Florence, where ls of work poured in on him from many quarters. g of France desired something from his hand to eside the two pictures he possessed by Raphael. horities of Bologna wanted him to design a façade r church of St Petronius; those of Genoa to cast a n bronze of their great commander, Andrea Doria. l Grimani begged hard for any picture or statue he ave to spare; other amateurs importuned him for n as a pencil drawing or sketch. Lastly his friend rtisan Sebastian del Piombo at Rome, ever eager to the feud between the followers of Michelangelo se of Raphael, besought him on Raphael's death to at once to Rome, and take out of the hands of the aster's pupils the works of painting still remaining ne in the Vatican chambers. Michelangelo complied ne of these requests. All that we know of his doing time was the finishing a commission received and t in hand four years previously, for a full-sized of a nude Christ grasping the Cross. This statue, ted and sent to Rome in 1521 (with some last touches by subordinate hands in Rome itself), stands now in rch of Sta Maria sopra Minerva; there is little in e Christian spirit as commonly understood, although, e parts which Michelangelo himself finished, there me accomplishment of design and workmanship.

next twelve years of Michelangelo's life (1522–34) ent at Florence, and again employed principally in the service of his capricious and uncongenial patro Medici. The plan of a great group of monume deceased members of this family, to be set up i mortuary chapel in San Lorenzo, seems to have been f and preparations to have been made by Michelang its execution, as early as 1519. It was not, howeve 1524, after Leo X. had died, and his successor Adri had been in his turn succeeded by another Medicean Clement VII., that any practical impulse was given work. Even then the impulse was a wavering one. Clement proposed to associate another artist, San with Michelangelo in his task. This proposal be Michelangelo's peremptory demand abandoned, C next distracted the artist with an order for a new tectural design, – that, namely, for the proposed M or "Laurentian" library. When at last the plans sepulchral monuments took shape, they did not incl had been at first intended, memorials to the foun the house's greatness, Cosimo and Lorenzo the Magn or even to Pope Leo X. himself, but only to two y members of the house lately deceased, Giuliano, Nemours, and Lorenzo, duke of Urbino. Miche brooded long over his designs for this work, and w engaged on its execution – his time being partly also up by the building plans for the Medicean library political revolutions interposed to divert his industr 1527 came to pass the sack of Rome by the Au and the apparently irretrievable ruin of Pope Clement Florentines seized the occasion to expel the Medi their city, and set up a free republican governmen more. Naturally no more funds for the work i Lorenzo were forthcoming, and Michelangelo, invitation of the new signory, occupied himself while with design for a colossal group of Sams the Philistines, to be wrought out of a block of which had been rough hewn already for another p by Baccio Bandinelli. Soon, however, he was ca help in defending the city itself from danger. Clem his enemy Charles V. having become reconciled, bot were now bent on bringing Florence again under the the Medici. In view of the approaching siege, Miche was appointed engineer in chief of the fortification spent the early summer of 1529 in strengthening defences of San Miniato, from July to September absent on a diplomatic mission to Ferrara and Returning in the middle of the latter month, he fou cause of Florence hopeless from internal treache from the overwhelming strength of her enemies. his dark seizures overcame him, and he departed suddenly for Venice. Not cowardice, but despair city's liberties, and still more of his own profession specters amid the turmoil of Italian affairs, was the of his departure. For a while he remained in negotiating for a future residence in France. Then the siege was still in progress, he returned once Florence; but in the final death struggle of her libe bore no part. When in 1530 the city submitted conquerors, no mercy was shown to most of those w taken part in her defence. Michelangelo believed in danger with the rest, but on the intervention of Valori he was presently taken back into favo employment by Pope Clement. For three years still remained at Florence engaged principally on t pletion of the Medici monuments, and on the continu the Medicean library, but partly also on a picture for the duke of Ferrara.

The statues of the Medici monument take rank beside t and the Slaves as the finest work of Michelangelo's cent in sculpture; moreover, though some of the figures are un they constitute as actually executed a complete scheme

of a Madonna and Child (left imperfect because the marble
rt in bulk), and of the two famous monumental groups, each
ng of an armed and seated portrait-statue in a niche, with
blematic figures reclining on each side of a sarcophagus
The portraits are treated not realistically but typically. In
Lorenzo seems to be typified the mood of brooding and
rated inward thought preparatory to warlike action; in
Giuliano, the type of alert and confident practical survey
tely preceding the moment of action. To this contrast of
lit ative and active character corresponds to some extent a
in the emblematic group accompanying the portraits. At
of the Duke Giuliano recline the figures of Night and Day,—
er a female, the latter a male personification—the former
an attitude of deep but uneasy slumber, the latter (whose
d face are merely blocked out of the marble) lifting himself
t wrathful and disturbed awakening. But for Michelangelo's
g grandeur of style, not for the sense which his works con
compulsive heat and tempest of thought and feeling in the
t thus conceived them, both these attitudes might be charged
travagance. Varied, but far less violent, are those of the
panion figure that recline between sleep and waking on
ophagus of the tomb of Lorenzo. Of these, the male figure
n as Evening and the female as Morning (*Crepuscolo* and
. In Michelangelo's original idea, figures of Earth and
were to be associated with those of Night and Day on the
nt of Giuliano, and others of a corresponding nature, no
ith those of the Morning and Evening Twilight on that of
, these hence afterwards fell out of the scheme. Michel-
obvious and fundamental idea was, as some words of his
nd, to exhibit the elements, and the powers of earth and

helangelo had never ceased to be troubled by the heirs
cutors of Julius, as well as by his own artistic con
and ambition, concerning the long postponed comple
the Julian monument. Agreement after agreement
en made, and then from the force of circumstances
In 1532, on the completion of the Medicean monu-
t Florence, he entered into a new and what he firmly
to be a binding contract to complete the work, on a
ee more very greatly reduced, and to set it up in the
of S. Pietro in Vincoli in Rome. But once more
hands of the pope diverted his purpose. Clement
that Michelangelo must complete his decorations
Sixtine chapel by painting anew the great end
ove the altar, adorned until then by frescos of
no. The subject chosen was the Last Judgment,
helangelo began to prepare sketches. For the
o years he lived between Rome and Florence, and
autumn of 1534, in his sixtieth year, settled finally
the remainder of his life at Rome. Immediately
rds Pope Clement died, and was succeeded by a
under the title of Paul III. Even more than his
s or, Paul insisted on claiming the main services of
ngelo for himself, and forced him to let all other
ment's stand. For the first seven years after the
return to Rome, his time was principally taken up
e painting of the colossal and multitudinous Last
nt. This being completed in 1541, he was next
led to undertake two more great frescos, one of the
sion of Paul and another of the Martyrdom of Peter,
w chapel which the pope had caused to be built in
tican, and named after himself *Cappella Paolina*.

resco of the Last Judgment in the Sixtine chapel is probably
t famous single picture in the world. In it Michelangelo
more than ever the omnipotence of his artistic science, and
y daring of his conceptions. The work exhibits the
unclothed human forms in every variety and extremity of
unattempted action and predicament. But of moderation,
as of beauty and tenderness, it is almost entirely devoid.
r from the complexion of his own thoughts, and the
digmatio that was native to his breast, or from the influ-
the passionate and embittered theological temper of the
Michelangelo has here neglected the consolatory aspects of
nity, and insisted on its terrific aspects almost exclusively.

Neither in the qualities of colour and execution is the wor
as the condition of either admits comparison, comparable f
to the earlier and far more nobly-inspired frescos of the
It is to these, and not to the Last Judgment, that the stud

joys of Platonic love, and the power and mysteries
Michelangelo's poetical style is strenuous and conc
like the man. He wrote with labour and much sel
tion; we seem to feel him flinging himself on the
of language with the same overwhelming ener
vehemence,—the same impetuosity of temperame
bined with the same fierce desire of perfection
which contemporaries describe him as flinging hi
the material of marble.

And so the mighty sculptor, painter, and poet
old age. An infirmity which settled on him in 15
the death of Vittoria Colonna in 1547, left him b
health and heart. But his strength held on for
year longer yet. His father and brothers were d
his family sentiment concentrated itself on a
Leonardo, to whom he showed unremitting practic
ness, coupled with his usual suspiciousness and f
of temper. In almost all his relations the old n
tinued to the end to manifest the same loyal and r
heart, accompanied by the same masterful, moo
estranging temper, as in youth. Among the a

the younger generation he held a position of absolute ascendency and authority; nor was his example, as we have said, by any means altogether salutary for them. During the last years of his life he made but few more essays in sculpture, and those not successful, but was much employed in the fourth art in which he excelled, that of architecture. A succession of popes demanded his services for the embellishment of Rome. For Paul III. he built the palace called after the name of the pope's family the Farnese. On the death of Antonio da San Gallo he succeeded to the onerous and coveted office of chief architect of St Peter's Church, for which he remodelled all the designs, living to see some of the main features, including the supports and lower portion of the great central dome, carried out in spite of all obstacles according to his plans. Other great architectural tasks on which he was engaged were the conversion of a portion of the Baths of Diocletian into the church of Sta Maria degli Angeli, and the embellishment and rearrangement of the great group of buildings on the Roman Capitol. At length, in the midst of these vast schemes and responsibilities, the heroic old man's last remains of strength gave way. He died on the threshold of his ninetieth year, on the 18th of February 1564.

For the bibliography of Michelangelo, which is extensive, see the useful though very imperfect compilation of Passerini, *Bibliografia di Michelangelo Buonarroti*, &c., Florence, 1875. The most important works, taken in chronological order, are the following. P. Giovio, supplement to the fragmentary *Dialogus de viris litteris illustribus*, written soon after 1527, first published by Tiraboschi, *Storia della Letteratura italiana*, Modena, 1871; G. Vasari, in *Vite degli più eccellenti architettori, pittori, e scultori*, &c., Florence, 1550; A. Condivi, *Vita di Michelangelo Buonarroti*, 1553; this account, for which the author, a pupil and friend of the master's, had long been collecting materials, was much fuller than that of Vasari, who made use of it in rewriting his own life of Michelangelo for his second edition, which appeared after the master's death (1568). The best edition of Vasari is that by Milanesi, Florence, 1878–83; of Condivi, that by Gori and Manette, Pisa, 1746. The first additions of importance were published by Bottari, *Raccolta di lettere sulla pittura*, &c., Rome, 1754 (2d ed., by Ticozzi, Milan, 1822); the next by Gaye, *Carteggio inedito*, 1840. Portions of the correspondence preserved in the Buonarroti archives were published by Guasti in his notes to the *Rime di Michelangelo Buonarroti*, 1863, and by Daelli in *Carte Michelangelesche inedite*, Milan, 1865. Complete biographies of Michelangelo had been meanwhile attempted by J. Harford, London, 1857, and with more power by Hermann Grimm, *Leben Michelangelo's*, Hanover (5th ed., 1879). A great increment of biographical material was at length obtained by the publication in the four hundredth year after Michelangelo's birth, of the whole body of his letters preserved in the Buonarroti archives,—*Lettere di Michelangelo Buonarroti*, ed. G. Milanesi, Florence, 1875. This material was first employed in a connected narrative by A. Gotti, *Vita di Michelangelo*, Florence, 1875. Next followed C. Heath Wilson, *Life and Works of Michelangelo Buonarroti*, Florence, 1876, the technical remarks in which, especially as concerns the fresco paintings, are valuable. Lastly, the combined lives of Michelangelo and Raphael by Professor A. Springer in Dohme's series of *Kunst u. Künstler*, Leipsic, 1878, contain the best biography of the master which has yet appeared. Of the poems of Michelangelo the best edition is that already referred to,—G. Guasti, *Rime di Michelangelo Buonarroti*, 1863; in earlier additions the text had been recklessly tampered with, and the rugged individuality of the master's style smoothed down. An edition with German translations was published by Hasenclever, Leipsic, 1875; for the English student the translations by Mr J. A. Symonds, in *Sonnets of Michelangelo and Campanella*, London, 1878, are invaluable. (S. C.)

MICHELET, JULES (1798–1874), one of the most voluminous and remarkable writers of France, and one who only lacked a keener power of self-criticism to make him one of the greatest, was born at Paris, August 21, 1798. He belonged to a family which had Huguenot traditions, and which was latterly occupied in the art of printing. His father was a master printer, but seems not to have been very prosperous, and the son at an early age assisted him in the actual work of the press. A place was offered him in the imperial printing office, but his father was able to send him to the famous Collège or Lycée Charle where he distinguished himself. He passed the un examination in 1821, and was shortly after appoint professorship or rather mastership of history in the Rollin. Soon after this, in 1824, he married. The of the Restoration and the July monarchy was one most favourable to rising men of letters of a sor scholastic cast that has ever been known in Fran Michelet had powerful patrons in Villemain, Cous others. But, though he was an ardent politician from his childhood embraced republicanism and a variety of romantic free-thought), he was first of al of letters and an inquirer into the history of th His earliest works were school books, and they w written at a very early age. Between 1825 and produced divers sketches, chronological tables, modern history. His *Précis* of the subject, publi the last mentioned year, is a sound and careful b better than anything that had appeared before written in a sober yet interesting style. In the sa he was appointed maître de conférences at the Normale. Four years later, in 1831, the *Introd l'Histoire Universelle* showed a very different style, ing no doubt the idiosyncrasy and literary power writer to greater advantage, but also displaying the visionary qualities which make Michelet the most s ing but the most untrustworthy (not in facts, w never consciously falsifies, but in suggestion) historians. The events of 1830 had unmuzzled h had at the same time improved his prospects, and in a better position for study by obtaining for him in the Record Office, and a deputy professorshi Guizot in the literary faculty of the university soon afterwards he began his chief and monument the *Histoire de France*, which occupied him for abo years, and of which we shall speak presently. accompanied this with numerous other works, el erudition, such as the *Œuvres Choisies de Vico*, the J *de Luther écrits par lui même*, the *Origines d Français*, and somewhat later the *Procès des Te* 1838 was a year of great importance in Michel He was in the fulness of his powers, his studies his natural aversion to the principles of author ecclesiasticism, and at a moment when the revived of the Jesuits caused some real and more pretende he was appointed to the chair of history at the Co France. Assisted by his friend Quinet, he began a polemic against the unpopular order and the p which it represented, a polemic which made their and especially Michelet's, one of the most popula of the day. He published, in 1839, a History Roman Republic, but this was in his graver and manner. The results of his lectures appeared volumes *Le Prêtre, la Femme, et la Famille* and *L* These books do not display the apocalyptic styl borrowed to a certain though no very great exte Lamennais, characterizes Michelet's later works, contain in miniature almost the whole of his curiou politico-theological creed a mixture of sentime communism, and anti-sacerdotalism, supported by eccentric arguments, but urged with a great eloquence. The principles of the outbreak of 1 in the air, and Michelet was not the least impo those who condensed and propagated them: m original lectures were of so incendiary a kind course had to be interdicted. But when the actu tion broke out Michelet, unlike many other men did not attempt to enter on active political life, an devoted himself more strenuously to his litera Besides continuing the great history, he undert

out, during the years between the downfall of Louis
e and the final establishment of Napoleon III., an
astic *Histoire de la Revolution Française*. Despite
use of its enthusiasm, this is by no means Michelet's
ok. The events were too near and too well known,
rdly admitted the picturesque sallies into the blue
e which make the charm and the danger of his
work. In actual picturesqueness as well as in general
y of picture, the book cannot approach Carlyle's;
s a mere chronicle of the events it is inferior to half
n prosaic histories older and younger than itself.
p d'état lost Michelet his place in the Record Office,
ugh not in any way identified with the republic
stratively, he refused to take the oaths to the
But the new *regime* only kindled afresh his
can zeal, and his second marriage (with Mademoiselle
Malairet, a lady of some literary capacity, and of
can belongings) seems to have further stimulated
ver. While the history steadily held its way, a
of extraordinary little books accompanied and
fied it. Sometimes they were expanded versions of
oles, sometimes what may be called commentaries
panion volumes. In some of the best of them
science, a new subject with Michelet, to which his
believed to have introduced him, supplies the text.
-t of these (by no means the best) was *Les Femmes
Revolution* (1854), in which Michelet's natural and
ble faculty of dithyrambic too often gives way to
and not very conclusive argument and preaching.
next, *L'Oiseau* (1856), a new and most successful
as struck. The subject of natural history was treated,
m the point of view of mere science, nor from that
nment, nor of anecdote, nor of gossip, but from that
author's fervent democratic pantheism, and the
though, as was to be expected, unequal, was often
nt. *L'Insecte*, in the same key, but duller, followed.
succeeded by *L'Amour* (1859), one of the author's
opular books, and not unworthy of its popularity,
rhaps hardly his best. These remarkable works,
amphlets half moral treatises, succeeded each other
le at the twelve months' interval, and the succession
not unbroken for five or six years. *L'Amour* was
ed by *La Femme* (1860), a book on which a whole
e of French literature and French character might
uded. Then came *La Mer* (1861), a return to the
history class, which, considering the powers of the
and the attraction of the subject, is perhaps a little
inting. The next year (1862) the most striking
Michelet's minor works, *La Sorcière*, made its
nce. Developed out of an episode of the history,
ll its author's peculiarities in the strongest degree,
nightmare and nothing more, but a nightmare of
t extraordinary verisimilitude and poetical power.
remarkable series, every volume of which was at
work of imagination and of research, was not even
shed, but the later volumes exhibit a certain fall
. The ambitious *Bible de l'Humanité* (1864), an
al sketch of religions, has but little merit. In *La
me* (1868), the last of the natural history series, the
of staccato style are pushed even further than by
Hugo in his less inspired moments, though as is
ble in the hands of such a master of language as
et the effect is frequently grandiose if not grand.
ls (1869), the last of the string of smaller books
ed during the author's life, is a tractate on educa-
ritten with ample knowledge of the facts and with
helet's usual sweep and range of view, but with
declining powers of expression. But in a book
ed posthumously, *Le Banquet*, these powers reappear
ir fullest. The picture of the industrious and
famishing populations of the Riviera is (whether
fact or not) one of the best things that Michelet ha
To complete the list of his miscellaneous works, two
tions of pieces, written and partly published at d
times, may be mentioned. These are *Les Soldats
Révolution* and *Légendes Démocratiques du Nord*.

The publication of this series of books, and the c
tion of his history, occupied Michelet during both c
of the empire. He lived partly in France, partly in
and was accustomed to spend the winter on the I
chiefly at Hyères. At last, in 1867, the great work
life was finished. As it is now published it fills n
volumes. The first of these deals with the early
up to the death of Charlemagne, the second wi
flourishing time of feudal France, the third with th
century, the fourth, fifth, and sixth with the H
Years' War, the seventh and eighth with the establi
of the royal power under Charles VII. and Louis XI
16th and 17th centuries have four volumes apiece
of which is very distantly connected with French
proper, especially in the two volumes entitled *Ren
and *Réforme*. The last three volumes carry on the
of the 18th century to the outbreak of the Revo
The characteristics which this remarkable history
with Michelet's other works will be noted presentl
present it may be remarked that, as the mere divi
subjects and space would imply, it is planned o
original principles. Michelet was perhaps the
historian to devote himself to anything like a pictu
history of the Middle Ages, and his account is s
most vivid though far from the most trustworth
exists. His inquiry into manuscript and printed auth
was most laborious, but his lively imagination, a
strong religious and political prejudices, made him
all things from a singularly personal point of
Circumstances which strike his fancy, or furnish con
texts for his polemic, are handled at inordinate
while others are rapidly dismissed or passed over alto
Yet the book is undoubtedly the only history of
which bears the imprint of genius, and in this respe
not soon likely to meet a rival.

Uncompromisingly hostile as Michelet was to the
its downfall and the accompanying disasters of the
once more stimulated him to activity. Not only
write letters and pamphlets during the struggle, bu
it was over he set himself to complete the vast task
his two great histories had almost covered by a *His
the Nineteenth Century*. He did not, however, live t
it further than Waterloo, and the best criticism
perhaps contained in the opening words of the intro
to the last volume—"l'âge me presse." The new r
was not altogether a restoration for Michelet, a
professorship at the Collége de France, of which
tended that he had never been properly deprived, v
given back to him. He died at Hyères on the
February 1874, and an unseemly legal strife betw
representatives took place as to his funeral.

The literary characteristics of Michelet are among th
clearly marked and also among the most peculiar in Frenc
ture. A certain resemblance to Lamennais has been alread
and to this may be added an occasional reminiscence of the
of Bossuet. But in the main Michelet, even in the minor c
style, is quite original and individual. His sentences and pa
are as different as possible in construction and rhythm f
orderly architecture of French classical prose. A very
device of his (somewhat abused latterly) is the omissio
verb, which gives the sentence the air of a continued inte
Elsewhere he breaks his phrase, not finishing the regula
at all. In these points and many others the resemblanc
contemporary Carlyle is very striking; and, different
their points of view, their manners of seeing were by no
unlike. History to Michelet is always picturesque; it is
of tableaux. Allusion has been already made to the singu

n which these tableaux are drawn, a perspective so strange
ader unacquainted with the actual size and relation of the
epresented is certain to be deceived. Nothing indeed is
rom Michelet's purpose than deceit. Although a strong
n, an ardent anti-sacerdotalist, and a patriot of fanatical
m, he is always scrupulously fair as far as he understands
is doing. For instance, his hatred for England and
nen is one of the most comically intense passions in litera-
is never tired of exclaiming against their diabolical pride,
ous jealousy of France, their calculating covetousness, and
In his excited imagination the long drama of European
s a kind of conflict of Ormuzd and Ahriman, in which
t is needless to say, plays the first part and England the
Yet he is never unfair to English fortitude and coolness,
ter the childish fashion of some of his countrymen) slurs
glish victories, and often expresses genuine admiration
t is true, with a shudder or two of aversion) for the master-
and constantly advancing prosperity of the English people.
ll his dislike to the priesthood, he never is chary of praise
r monk whenever it can fairly be given, and, with all his
nism, he is never weary of worshipping the heroism of a
g. But his poetical fashion of dealing with events, his
ion of trivial incidents into great facts of history, his fixed
ecially in reference to the intellectual and social condition
val times, the evils of which he enormously exaggerates,
bding prejudices of a general kind combine to distort his
n the strangest fashion. A laborious person might pick
ntemporary authors a notable collection of erroneous views
Michelet is not so much the author as the suggester, for it
his brilliant exaggerations are torn from their context and
in some quite other context as sober gospel that they are
leading to those who do not know the facts, and most
to those who do. This is especially the case in regard to
. Michelet began his great work too early to enjoy the
the resurrection of old French literature which has since
ce; and though his view of that literature partakes of the
enthusiasm which colours his view of everything French,
ndingly incorrect in detail. The most remarkable passage
haps is the passage in his *Renaissance* relating to Rabelais,
and Du Bellay, a passage so widely inconsistent not only
d criticism but with historic fact that the author (a very rare
h him) makes a kind of half apology for it elsewhere. Of
of the age of chivalry proper, the chansons de gestes, the
n romances, the early lyrics and dramas, he evidently knew
, and chose to subordinate what he did know to his general
f the time. Even much later his praise and blame, though
ntly honest, are quite haphazard. Unless, therefore, the
gifted with a very rare faculty of applying the "grain of
what he reads, or unless he be well acquainted with the
cts before coming to Michelet's version of them, he will
ertainly be misled. But despite this grave drawback
ttends all picturesque history) the value of Michelet merely
storian is immense. Not only are his separate tableaux,
derful geographical sketch of France in the beginning of
, the sections devoted to the Templars, to Joan of Arc, to
issance, to the Camisards, almost unequalled, but the in-
and stimulating effect of his work is not to be surpassed.
onstruction is often hazardous and conjectural, sometimes
and demonstrably mistaken, and nearly always difficult
entirely to the ascertained facts, it is always possible in
ways instinct with genius, and always life-like. There are
ones in Michelet: they are at anything only too stirring
y. These criticisms apply equally to the minor books,
hese are necessarily fuller of the author's somewhat weari-
paganda, and less full of brilliantly painted facts. The
lt of Michelet as of not a few other modern authors is the
tively improvised and ephemeral character of too much of
. His immense volume is, much of it, mere brilliant
teering, much more mere description equally brilliant but
iable to pass. Nevertheless he is (especially in French, the
par excellence of measured and academic perfection) so
ristic and singular a figure in his turbid eloquence and
shing insight that he is never likely to lose a place, and a
one, in literary history.

t all Michelet's works, the exceptions being his translations,
ions, &c., are published in uniform size and in about fifty
partly by Marpon and Flammarion, partly by Calmann

(G. SA.)

HELL, JOHN, an eminent English man of science
8th century. He received his university education
een's College, Cambridge. His name appears
in the Tripos list for 1748-49; and in 1755 he was
tor in that examination. He was a fellow of his
and became successively Woodwardian professor
gy (in 1762) and rector of Thornhill in Yorkshire.
He was elected a member of the Royal Society in the same year as Henry Cavendish (1760). He died in 1793. In 1750 he published at Cambridge a small work of some eighty pages, entitled *A Treatise of Artificial Magnets, in which is shown an easy and expeditious method of making them superior to the best natural ones*. Besides the description of the method of magnetization which still bears his name, this work contains a variety of acute and accurate magnetic observations, and is particularly distinguished by a lucid exposition of the nature of magnetic induction. He is now best known as the original inventor of the torsion balance, which afterwards became so famous in the hands of its second inventor Coulomb. Michell described it in his proposal of a method for obtaining the mean density of the earth. He did not live to put his method into practice; but this was done by Henry Cavendish, who made, by means of Michell's apparatus, the celebrated determination that now goes by the name of Cavendish's experiment (*Phil. Trans.*, 1798).

Michell's other contributions to science are—"Conjectures concerning the Cause and Observations upon the Phenomena of Earthquakes," *Phil. Trans.*, 1760, "Observations on the Comet of January 1760 at Cambridge," *Ib.*, 1760, "A Recommendation of Hadley's Quadrant for Surveying," *Ib.*, 1765, "Proposal of a Method for measuring Degrees of Longitude upon Parallels of the Equator," *Ib.*, 1766; "An Inquiry into the Probable Parallax and Magnitude of the Fixed Stars," *Ib.*, 1767; "On the Twinkling of the Fixed Stars," *Ib.*, 1767, "On the Means of Discovering the Distance, Magnitude, &c., of the Fixed Stars," *Ib.*, 1784.

MICHELOZZI, MICHELOZZO (1391-1472?), was a Florentine by birth, the son of a tailor, and in early life a pupil of Donatello. He was a sculptor of some ability in marble, bronze, and silver. The statue of the young St John over the door of the Duomo at Florence, opposite the Baptistery, is by him; and he also made the beautiful silver statuette of the Baptist on the altar frontal of San Giovanni. Michelozzi's great friend and patron was Cosimo I. dei Medici, whom he accompanied to Venice in 1433 during his short exile. While at Venice, Michelozzi built the library of San Giorgio Maggiore, and designed other buildings there. The magnificent Palazzo dei Medici at Florence, built by Cosimo, was designed by him, it is one of the noblest specimens of Italian 15th-century architecture, in which the great taste and skill of the architect has combined the delicate lightness of the earlier Italian Gothic with the massive stateliness of the Classical style. With great engineering skill Michelozzi shored up, and partly rebuilt, the Palazzo Vecchio, then in a ruinous condition, and added to it many important rooms and staircases. When, in 1437, through Cosimo's liberality, the monastery of San Marco at Florence was handed over to the Dominicans of Fiesole, Michelozzi was employed to rebuild the domestic part and remodel the church. For Cosimo I. he designed numerous other buildings, mostly of great beauty and importance. Among these were a guest house at Jerusalem for the use of Florentine pilgrims, Cosimo's summer villa at Careggi, and the strongly fortified palace of Cafaggiuolo in Mugello. For Giovanni dei Medici, Cosimo's son, he built a very large and magnificent palace at Fiesole. In spite of Vasari's statement that he died at the age of sixty-eight, he appears to have lived till 1472. He was buried in the monastery of San Marco, Florence. Though skilled both as a sculptor and engineer, his fame chiefly rests on his architectural works, which claim for him a position of very high honour even among the greatest names of the great 15th-century Florentines.

MICHIGAN, one of the States of the American Union, situated in the region of the great lakes. It lies between 41° 42′ and 47° 32′ N. lat., and 82° 24′ and 90° 31′ W. long., the centre of the State being 670 miles north of west from New York, the nearest point on the seaboard. The area is 58,915 square miles. The State consists of two

MICHIGAN

divisions, known as the Upper and the Lower
ula. The Upper or Northern Peninsula is bounded
N., E., and S. by Lakes Superior, Huron, and
an, and on the W. by the river St Mary and the
f Wisconsin. The Lower Peninsula is bounded on
, N., and E. by Lakes Michigan, Huron, St Clair,
rie, and the St Clair and Detroit rivers, and on the
e States of Ohio and Indiana. The general contour
Lower Peninsula approaches that of a horse-shoe,
n average width of about 200 miles from east to
nd a length of about 300 miles from north to south.
face gradually rises in gentle undulations from the
nding lake to an elevation of about 400 feet above
Huron, no point reaching an altitude of more than
et. The Upper Peninsula is much more rugged in
r and surface, at some points reaching an elevation
t 1100 feet. The territory was originally covered
rests, with only here and there a small open prairie.
unds on five inland lakes, with areas varying from
res to several miles. The rivers are not large
to be navigable, but they afford ample water-power,
particularly valuable for floating down the logs of
mbering districts. The coast line of the State is not
n about 1600 miles in length, and along the whole
distance vessels of 2000 tons may pass without
sight of land.

gical Formation. The Lower Peninsula occupies
ntral part of a great basin, the borders of which
to the east as far as London, Ontario, and to the
far as Madison, Wisconsin. Within these limits
veller starting in any direction from the centre of
ate encounters successively the out cropping edges
er and older strata. The whole series has been
to a nest of wooden dishes; it embraces not
he Laurentian and Huronian systems but also
merous groups that go to make up the Silurian,
evonian, the Carboniferous, and the Quaternary
. These several formations are covered almost
ally with a drift of finely comminuted and triturated
borne thither by moving glaciers and floating
s, or washed to its present position by currents
er, while the surface was still submerged. This
aterial varies in thickness, sometimes extending to
of 200 or 300 feet. While the lower formations
almost inexhaustible deposits of copper, iron,
, and salt, the surface soil is pre-eminently fertile,
all the mineral constituents necessary for the most
ut growth of plants. There are limited areas of
nd somewhat sterile drift soil; but even these
hown themselves under proper treatment to be
of yielding a rich vegetation. For the most
he drift soil is composed of a mixture of clay
nd and gravel. It is easily cultivated, is retentive
ture, and is sufficiently porous to prevent the injury
s by excessive rains.

ate and Natural Products. The mean temperature
sing, the capital of the State, as determined by
ations extending through eighteen years, is 46·71
or about the same as that of Berlin. During the
r months the mean temperature is nearly the same as
Vienna; in the winter it is nearly that of Stockholm.
nual rainfall during the eighteen years previous to
was about 31 inches. This is very evenly distributed
hout the year, though a little more than half the
falls in the five months from May to October.
erage snowfall in the centre of the State is about 4
ough it is seldom that more than 12 inches lie on the
at any one time. The winter temperature is much
d by the open water of the adjacent lakes. The
winds are commonly from the west and north west;
but in sweeping across the open waters of Lake Mic
they are so far softened as to make the climate
milder than that found in the same latitude on the we
side of the lake. This peculiarity is specially favoura
the growth of fruits. Peaches are grown successfully
the 45th parallel, and figs thrive in the open air in lat.
The modifying influence of the lake winds also gives
variety to the flora. The predominant woods are oak, m
beech, elm, ash, cherry, hickory, walnut, basswood, and
All these grow luxuriantly in the vast forests of the S
and afford an abundant supply of the best timber. The
165 species of trees and shrubs indigenous to Mich
and the entire flora of the State makes a list of
species.

Cereals and Fruits. The most important crop of Mic
is wheat, and the average yield per acre, as shown b
latest census, is greater than that of any other State i
Union. The acres own in 1879 were reported as 1,822
and the amount produced as 35,532,543 bushels.
figures show that Michigan is fourth in rank of the w
producing States, the number of bushels grown
exceeded by the crops of Illinois, Ohio, and Indiana
1879 the yield in bushels of the other principal cere
shown by the following figures: Indian corn, 32,461
oats, 18,190,793; barley, 1,204,316; rye, 294,918;
wheat, 413,062; clover seed, 313,063; pease, 538
The crop of potatoes in the same year was 8,02
bushels, and the hay amounted to 1,051,115 tons
the fruits grown in the State apples are the most impo
and these are believed to be unsurpassed in excelle
any country in the world. The sales in 1880
1,831,936 bushels, a considerable quantity going t
markets of Europe. Next in importance is the peach
annually gathered from more than fifty of the count
the State. In 1880 the peach orchards were report
covering 12,908 acres, and the fruit sold as amount
113,118 bushels. The long coast-line of Lake Mic
affords easy access to market even for the most peris
fruits. Besides the facilities thus afforded, the rai
that now thread the State, with an aggregate leng
March 1882 of 4332 miles, afford abundant mea
rapid transportation. As the fruit belt extends from
to south more than 200 miles, the danger of disa
competition in the markets is obviated by prolongat
the season of ripening. At the meeting of the
Horticultural Society held in 1881 it was reported
the average value of the peach crop per acre was
$125. The ten volumes of the *Transactions* of the
Horticultural Society published since its organizati
1870 show that the development of fruit culture
the last decade has been much more rapid than i
other State.

Lumber. The timber produce in Michigan is of su
quality, and the amount is so great that about two-
of the best lumber sold in New York, Philadelphi
Boston go out from its mills. The logs are borne
the lakes, rivers, and small watercourses to the boo
mills situated at convenient points, where the lum
sawed and shipped for the different markets of the
Of these manufacturing districts those known a

f the largest and finest mills of the world In 1854, he first effort was made to collect statistics of this y, it was found that there were only sixty one mills ration, and that the entire annual product was only 0,000 feet Eighteen years later, in 1872, it was ted that the annual product was not less than 000 feet of oak, 12,700,000 of staves, 300 000 000 00,000,000 shingles, and 2, 00,000 000 of wood The number of saw mills had already reached about the number of persons employed 20,000 and the represented $25,000,000 In 1881 the manufacture lumber amounted to 3,919,500,000 feet the value h exceeded $60,000,000 The aggregate value of est products of the State was estimated in 1881 ve reached more than $1,000,000,000 *Tenth Census*, No 6, issued December 1, 1881, estimated the t of standing white pine of merchantable quality at ,000,000 feet, and the amount of standing hard at 700 000,000 cords Besides the amount the authority estimates the amount of hemlock at 000,000 feet with 7,000,000 cord of hard wood ate of 70,000,000 of cedar and tamarack It is le that before many years the hard wood produced State will approach in value the figure representing ue of the pine now sent to the markets of the world robable that Michigan for many years to come will n its precedence as a lumber producing State.

ral Resources Of the mineral products of Michigan st important is iron As early as 1847 the report first State geologist, Dr Douglass Houghton called on to the presence of hematite on the shores of able time after this it was not found in such ties as to make it certain that mining could be made ble Before 1860, however, it became known that n the Upper Peninsula not only existed in vast ties, but also that it was of superior quality From me iron mines were rapidly developed, until in they had come to exceed in value though not in t, even the products of Pennsylvania In 1880 oduct was 1,834,712 tons, with a value at the mines 034,648, as against the yield in Pennsylvania of 57.5 tons, with a value of $5, 17,079 The product higan in 1882 was 2,948, 07 tons of ore, with a value of about $25,000,000 The Michigan ds are of extraordinary richness 62 9 per cent the average of the first class ores, while the furnace often show a much higher yield

t in importance to the iron mines are those of copper are also situated in the Northern Peninsula, in the ain range of trappean rocks which crown the point l extending northwards into Lake Superior This ary peninsula or cape, known as Keweenaw Point o an average height of about 600 feet above the lake, ghest pinnacles reaching nearly double that altitude oint contains what are believed to be the richest -mines ever discovered, the metal is not found as , but as virgin copper almost chemically pure It ly to be separated from its rocky matrix, when it is for the market The largest of the copper mines, Calumet, has built up an industry which employs nen, and its total product of refined copper in 1882 o less than 50,770,719 lb, or one eighth of the production of copper in the world In quality the of the Lake Superior district is such that it commands the highest price at home and abroad Its tenacity arkable, and therefore it is eagerly sought after for ges by all the great military powers. In 1882 the -mines paid dividends amounting to $2,900,000, ing an aggregate of $28,248,000 since they were d.

Within a few years the salt works of Michigan have come to exceed those of any other State in the The first well was sunk in 1859-60, but in 1882 the duction was found to have exceeded that of the works in New York, and to have amounted in the to no less than 3,204,921 barrels. The extraordinary development of this industry is due to several causes careful system of inspection by State authority has its salt unsurpassed in purity. The salt basin is now accessible by navigable waters, so as to have the advantage of cheap transportation, but the wells are situated great lumber-producing districts, and the manufacture thus carried on at very small expense, in connection with the saw mills. The power is furnished by the engines, the exhausted steam is used for the evaporation of brine during the day, and during the night evaporation is still carried on by means of refuse wood and dust, while the staves for barrels are made from refuse timber By this system the best quality of salt is obtained at a minimum expense. The chief reservoir of salt is a series of sand-stones and shales constituting the Waverly group. This salt producing rock covers no less than 8000 square miles, and it is safe to presume that the supply is inexhaustible. The average depth of the wells is about 800 feet, but in some localities wells sunk to nearly 2000 feet have been remunerative. Important salt works have recently been developed in the western part of the State.

There are also certain other minerals of considerable importance. Deposits of gypsum, easily accessible and practically inexhaustible in quantity, and superior in quality are found in several localities both in the eastern and in the western parts of the Lower Peninsula. In the county of Grand Rapids the deposit crops out at the surface, with an average depth of from 10 to 70 feet extends over an area of 10 or 12 square miles. The rock is easily quarried and is either ground for use as a fertilizer or calcined for plaster of Paris. The deposits of coal are supposed to cover about 8000 square miles, but as yet the production at any one point has not been very considerable. In quality the coal is highly bituminous, and is not sufficiently pure to be useful for smelting or for the manufacture of gas. For these reasons the stock of coal in the State is practically untouched. If future explorations and developments should make these deposits available, a new era in the manufacture of iron will be the result. At present the coal for smelting the Lake Superior ores is brought chiefly from Ohio and Pennsylvania Quarries of limestone and of sandstone have been opened in various parts of the State. The brown stone of the Upper Peninsula is of excellent quality, and is capable of receiving a fine finish. The supply is inexhaustible, and the access afforded to the quarries by water gives promise of a thriving industry. The grindstones taken from the Huron Bay quarries are of superior quality, and the slates found in unlimited quantities on the shores of the Huron Bay are unsurpassed in point of durability and colour. Clay and sands of commercial value are found in great abundance. Though the manufacture of glass is yet in its infancy, sands in large quantities have been discovered in Wayne county suitable for the manufacture of plate glass of excellent quality. Brick and tile clays are found in all parts of the State. Though native silver has been found in small quantities in the Upper Peninsula, the systematic working of this metal has not yet been carried on with such results. The *Report* of the commissioner of mineral statistics for 1882 shows that, except as to coal, Michigan is the foremost of all the States in mineral wealth.

Fisheries.— The geographical position of Michigan explains the fact that its fresh-water fisheries are the most productive in the United States. The most important varieties of fish are lake

MICHIGAN

, bass, pickerel, herring, brook-trout grayling, and white-
eneral laws for the protection of fish have been passed; and
ommission has been maintained for some years for the
of propagating the best varieties and planting them in
daptated to their natural development. Up to the close of
e commissioners had planted about 80,000,000 young white-
00,000 silver eels, 1,000,000 lake trout, 2,000,000 salmon,
,000 brook trout, besides smaller numbers of shad, grayling,
d bass. Excellent results have followed, especially in the
ation of white-fish, salmon and eels. In 1879 the total
was 21,913,100 lb, of which 2,902,250 lb were white-fish,
st valuable lake-fish known to epicures and to commerce.
winter large quantities preserved by freezing are taken to
markets, where they are readily sold at a high price.

ational Institutions. As early as 1785 the law of congress
rovided for the sale of land north of the Ohio river reserved
support of public schools "section 16" of each township.
ndamental law devoted to educational purposes one thirty
f all the lands of that vast domain known as the north-
territory. The "Ordinance of 1787," by which this
was organized, further provided that "school and the
of education shall for ever be encouraged." In 1826 this
eneral action was supplemented by a grant to Michigan of
nships of land for the founding and support of a university.
hen Michigan became a State in 1837, its educational policy took
form. The constitution provided, not only that the grant
tion 16" should be devoted exclusively to the support of
of the primary grade, but also that the State and not each
should be the custodian of the lands so appropriated.
stitution expressly provided that the proceeds from the
"school lands" should be held by the State as a perpetual
e interest of which should be annually applied to the sup
primary schools. The land devoted to school purposes in
n under these provisions amounted to 1,077,709 acres, of
n September 1881, 675,000 acres had been sold. On the
lized by these sales, $3,095,679, the State pays interest at
ent, and the resulting income, amounting to $216,645, is
distributed to the schools. This source is supplemented
al taxes, so that in 1881 the total sum realized from all
for the primary schools was $3,611,778.

chools organized under State law are known as graded and
l. In the small districts where the schools are under the
of but one or two teachers, grading is impracticable. Of
l districts there were in 1881 6170, attended by 215,570
, while the graded schools were 491 in number, with an
ce of 152,043. The school census includes all children
the ages of five and twenty, amounting in 1881 to 548,317, of
ere was an average attendance of 391,491. To all children
l age the public schools are free, though a fee may be re-
n advanced studies in the high schools. The immediate
tration of the schools is entrusted to school officers elected
by the tax payers of the individual districts. The State
tion requires that a free school shall be in session at least
onths of every year in each district. In districts of more
and less than 800 children, the law requires at least five
of school, while in districts of more than 800 children,
ion must be not less than nine months in length. In the
chools the division is into primary schools, grammar schools,
h schools, each of these divisions retaining the scholar
ly four years. At the end of the course the student is ready
university, to which, under certain restrictions provided by
self, he is admitted on diploma from the high
The university of Michigan, situated at Ann Arbor, was
ed for instruction in 1841. It now (1883) consists of the
ent of literature, science, and the arts, the department
ine, the department of law, the college of homœopathic
, the school of pharmacy, the college of dental surgery,
school of political science. Connected with the medical
ents are the State hospitals. In 1881-82 there were 86
of instruction and 1571 students. The total income for the
379 80 from Federal grant, State grants, and fees was
9. The general control of the university is placed in the
eight regents elected by popular suffrage at the biennial
elections, two regents being chosen at each election. The
school, situated at Ypsilanti, and generously supported by
e, may be said to complete the school system.

Public and Reformatory Institutions. A school for the deaf,
nd blind, instituted under an Act passed in 1848, is situated
, about 60 miles north-west of Detroit: in February 1882 it
9 pupils. In 1879 a distinct school for the training of the
as established at Lansing. The "State public school for
nt and neglected children" is devoted to the systematic
n of such children as otherwise would have to be maintained
ounty poorhouses. The pupils are divided into "families"
thirty each, and are cared for in separate cottages, each
being under the charge of a "cottage manager." The
eceives dependent children of sound health, and free from
contagious disease; and it is made the duty of the officers
charge of the poor to send all such children between the
three and twelve to it. This institution, the pioneer of i
and one of the most useful of charitable schools, is situated
water, 132 miles south-west of Detroit. In February 18
were 320 children and 21 officers and teachers. The "
School" at Lansing is designed to reclaim juvenile offend
have been convicted of some offence. A farm of 224 acres c
with the school is, in considerable part, tilled by the boy
number of inmates in February of 1882 was 325. A simila
at Adrian has recently been instituted for girls. There a
asylums for the insane at Kalamazoo (715 patients) and
(499 patients). The legislature of 1881 provided for the e
ment of an additional asylum in one of the northern counti
Lower Peninsula.

Population. In 1837 the State had 174,647 inhabitant
numbers according to the different census returns from 1
given in the following table:—

Years	Total			Density per Square
1840	212,267	113,588	98,479	
1850	397,654	209,897	187,757	
1860	749,113	394,694	354,419	12
1870	1,184,059	617,745	566,314	20
1880	1,636,937	862,678	774,259	

At the last census 388,508 of the inhabitants were of foreig
97,340 being natives of the United Kingdom, 89,085 Germa
16,115 Scandinavians. In point of population the State
was twenty-third in 1840, now stands ninth in the Union.

The following are the principal cities in the State, wit
lation at the census of 1880:—Detroit, 116,340; Grand Rap
32,016; Bay City, 20,693; East Saginaw City, 19,016;
City, 16,105; Muskegon City, 11,262; Saginaw City, 10,52
Huron, 8883, Flint City, 8410; Lansing (the State
8319; Ann Arbor, 8061, Adrian City, 7849; Battle Creek
Manistee, 6930; West Bay City, 6397; Alpena City
Ishpeming, 6039.

History and Government.—The State of Michigan is pa
territory that was first settled by the French, and until th
Canada into the hands of the British after the middle of
century was under the government of New France. The
was explored by Jesuit missionaries in the 17th centu
although it was known at an early period that the lan
of exceptional excellence, very little progress was made in
ing the resources of the territory until after the compl
the first half century of the American Union. The s
employed by the general government to inspect the lan
report as to their fitness for settlement by the soldiers of
of 1812 appear to have derived their impressions almost exc
from the low lands in the south-eastern corner of the territor
report, accordingly, was not favourable; and consequently
of immigration that had already begun to set in flowed
past Michigan into the territories farther west. It was la
this reason that the early development of Indiana, Illinoi
and Wisconsin was somewhat more rapid than that of M

CHIGAN, Lake. See St Lawrence.

CHIGAN CITY, a town of the United States, in e county, Indiana, on the south-east shore of Lake gan, 40 miles east-south-east of Chicago. As a ort and a junction for several railroads, it is a of considerable prosperity. It is the largest lumber t in the State, and one of the largest in the west, as numerous manufacturing establishments. The rn State prison (with 577 convicts at the close of is one of the principal buildings. The population sed from 3985 in 1870 to over 10,000 in 1883.

CHMASH (מִכְמָשׂ, מִכְמָס), the scene of one of the triking episodes in Old Testament history (1 Sam. comp. vol. xii. p. 403), was a place in Benjamin, 9 Roman miles north of Jerusalem (*Onom.*, ed. Lag., 0). Though it did not rank as a city (Josh. xviii.), Michmash was recolonized after the exile (Neh. xi. nd, favoured by the possession of excellent wheat *Mishna*, Men. viii. 1), was still a very large village ás) in the time of Eusebius. The modern Makhmas e a small place.

historical interest of Michmash is connected with the cal importance of the position, commanding the north side Pass of Michmash, which made it the headquarters of the nes and the centre of their forays in their attempt to quell t rising under Saul, as it was also at a later date the head- s of Jonathan the Hasmonæan (1 Mac. ix. 73). From en to Mount Ephraim there are two main routes. The pre- avan road keeps the high ground to the west near the water- nd avoids the Pass of Michmash altogether. But another he importance of which in antiquity may be judged of from 28 *sq.*, led southwards from Ai over an undulating plateau to ash. Thus far the road is easy, but at Michmash it descends very steep and rough valley, which has to be crossed before ding to Geba.[1] At the bottom of the valley is the Pass of ash, a noble gorge with precipitous craggy sides. O he crag is crowned by a sort of plateau sloping backwards ound-topped hill. This little plateau, a ut a mile east of esent village of Makhmás, seems to have been the post of ilistines, lying close to the centre of th insurrection, yet ing unusually good communication with their establishments nt Ephraim by way of Ai and Bethel, and at the same time nding the routes leading down to the Jordan from Ai and ichmash itself.

CKIEWICZ, Adam (1798–1855), Polish poet, was n 1798, near Nowogrodek, in the present government nsk, where his father, who belonged to the schlachta ser nobility, had a small property. The poet was ted at the university of Vilna; but, becoming ed in some political troubles there, he was forced minate his studies abruptly, and was ordered to live time in Russia. He had already published two small es of miscellaneous poetry at Vilna, which had been rably received by the Slavonic public, and on his l at St Petersburg he found himself admitted to the g literary circles, where he was a great favourite both his agreeable manners and his extraordinary talent provisation. In 1825 he visited the Crimea, which ed a collection of sonnets in which we may admire the elegance of the rhythm and the rich Oriental ring. The most beautiful are *The Storm*, *Bakchi-* and *Grave of the Countess Potocka*.

1828 appeared his *Konrad Wallenrod*, a narrative describing the battles of knights of the Teutonic with the heathen Lithuanians. Here, under a thin Mickiewicz represented the sanguinary passages of and burning hatred which had characterized the long of the Russians and Poles. The objects of the poem, gh evident to many, escaped the Russian censors, and it was suffered to appear, although the very n taken from Machiavelli, was significant: "Dovete adu sapere come sono duo generazioni da combattere bisogna essere volpe e leone." After a five years' ex Russia the poet obtained leave to travel: he had se made up his mind never to return to that country or l so long as it remained under the government o Muscovites. Wending his way to Weimar, he there the acquaintance of Goethe, who received him cord and, pursuing his journey through Germany, he en Italy by the Splügen, visited Milan, Venice, and Flo and finally took up his abode at Rome. There he the third part of his poem *Dziady*, the subject of wh the religious commemoration of their ancestors pra among Slavonic nations, and *Pan Tadeusz*, his l poem, by many considered his masterpiece. A gr picture is drawn of Lithuania on the eve of Napo expedition to Russia in 812. In 1832 Mickiewi Rome for Paris, where his life was for some time in poverty and unhappiness. He had married a lady, Selma Szymanowska, wh became insane. In he was appointed to th newly founded chair of Sla languages and literatu in the Collége de France, which he was especially qualified to fill, as he was the chief representative of Slavonic literature, Pou having died in 1837. He was, however, only destin hold it for a little more than three years, his last l having been given on the 28th of May 1844. His had become more and more disordered under the inf of religious mysticism. His lectures became a med religion and politics, and thus brought him under the c of the Government. A selection of them has been pub in four volumes. They contain some good sound crit but the philological part is very defective, for Mick was no scholar, and he is obviously only well acqu with two of the literatures, viz., Polish and Russia latter only till the year 1830. A very sad picture declining days of Mickiewicz is given in the memo Herzen. At a comparatively early period the unfor poet exhibited all the signs of premature old age; po despair, and domestic affliction had wrought their upon him. In 1849 he founded a French news *La Tribune des Peuples*, but it only existed a year. restoration of the French empire seemed to kind hopes afresh; his last composition is said to have Latin ode in honour of Napoleon III. On the ou of the Crimean War he was sent to Constantinople to in raising a regiment of Poles to take service again Russians. He died suddenly there in 1855, and his was removed to France and buried at Montmorency.

Mickiewicz is held to have been the greatest Slavonic poe the exception of Poushkin. Unfortunately in other parts of he is but little known; he writes in a very difficult langua one which it is not the fashion to learn. There were both and irony in the expression used by a Polish lady to a fo "Nous avons notre Mic ez à nous." He is one of the b nets of the so-called romantic school. The Poles ha roamed under the yoke of the classicists, and the country t legends and picturesque stories which only awaited the oet to put them into shape. Hence the great popularity his countrymen of his ballads, each of them being connect some national tradition. Besides *Konrad Walle* a *Tadeu* attention may be called to the poem *G* , desert the adventures o a Lithuanian chieftainess i Teuto knights. It is said by Ostrowski to have insp brave Emilia Plater, who was the heroine of th ellion and after having fought in the ranks of the insurgents, grave in the forests of Lithuania. A fine vigorous Oriental *Farys*. Very good too are the odes to Y uth and to t torian Lelewel; the former did much to stimulate the effort Poles to shake off their Russian conquerors. It is enough of Mickiewicz that he has obtained the proud position of th sentative poet of his country; her customs, her superstiti history, her struggles are reflected in his works.

[1] Isa. x. 28 describes the invader as leaving his heavy baggage hmash before pushing on through the pass.

KLE, William Julius (1734–1788), son of the
r of Langholm, Dumfriesshire, holds a respectable
mong the imitative minor poets of the 18th century.
rote a poem on *Knowledge*—carefully versified,
g a moral on the vanity of intellectual pride—
age of eighteen, entered into business as a brewer
father's request and against his own inclinations,
became bankrupt, went to London on outlook for
ts a man of letters, solicited patronage in vain,
a living hardly by writing for magazines, made
mpression in 1760 by "a poem in the manner of
r" called the *Concubine* (afterwards *Syr Martyn*),
pointed corrector to the Clarendon Press, and finally
place among the leading poets of that very barren
y a translation of the *Lusiad* of Camoens into heroic
ts (specimen published 1771, whole work 1775).
t was the repute of the work that when Mickle
ted secretary to Commodore Johnstone visited
in 1779 the king of Portugal gave him a public
on. As a translator of Camoens Mickle has been
ded, but he aimed, not at close rendering of the
l, but at making a poem which should be worthy of
nent place in English literature. This ambition
not capable of fulfilling, though he had great
and vigour. It may be doubted whether the
able forms which he imitated were the best suited
natural gifts. He shows delight in lively action, a
of dramatic effect, and, in the *Concubine*, the sub-
of which might have been conceived by Crabbe,
rable fulness of detail in coarse realistic painting.
ly, if the Scottish poem *There's nae luck about the*
as Mickle's, he mistook his medium. Scott read
mired Mickle's poems in his youth, and, besides
g *Kenilworth* on the ballad of *Cumnor Hall*, was a
al influenced by him in style. Mickle's prose is
nd vigorous.

ROMETER, an instrument generally applied to
es and microscopes for measuring small angular
s with the former or the dimensions of small
with the latter.

re the invention of the telescope the accuracy of
nical observations was necessarily limited by the
hat could be distinguished by the naked eye. The
etween two objects, such as stars or the opposite
of the sun, was measured by directing an arm
ed with fine "sights" (in the sense of the "sights"
e) first upon one of the objects and then upon the
er by employing an instrument having two arms
rnished with a pair of sights, and directing one
sights upon one object and the second pair upon
er. The angle through which the arm was moved,
he latter case, the angle between the two arms, was
f upon a finely graduated arc. With such means no
gh accuracy was possible. Archimedes concluded
s measurement that the sun's diameter was greater
7 and less than 32′; and even Tycho Brahe was so
by his measures of the apparent diameters of the
l moon as to conclude that a total eclipse of the sun
possible.[1] Maestlin in 1579 determined the relative
rs of eleven stars in the Pleiades (*Historia Cœlestis*
Baretti, Augsburg, 1666), and Winnecke has shown
ly Notices R. A. S., vol. xxxiv. p. 116) that the
le error of these measures amounted to about

The invention of the telescope at once extended
possibilities of accuracy in astronomical measurem
The planets were shown to have visible disks, and
attended by satellites whose distance and position
relative to the planet it was desirable to measure
became, in fact, essential to invent a "micrometer
measuring the small angles which were thus for the
time rendered sensible. There is now no doubt
William Gascoigne, a young gentleman of Yorkshire
the first inventor of the micrometer. Crabtree, a frie
his, taking a journey to Yorkshire in 1639 to see Gasc
writes thus to his friend Horrocks. "The first thin
Gascoigne showed me was a large telescope amplifie
adorned with inventions of his own, whereby he ca
the diameters of the sun and moon, or any small an
the heavens or upon the earth, most exactly throug
glass, to a second." The micrometer so mentione
into the possession of Mr Richard Townley of Lanca
who exhibited it at the meeting of the Royal Society
on the 25th July 1667.

The principle of Gascoigne's micrometer is tha
pointers, having parallel edges at right angles t
measuring screw, are moved in opposite directions
metrically with and at right angles to the axis
telescope. The micrometer is at zero when the two
are brought exactly together. The edges are then sepa
till they are tangent to the opposite limbs of the d
the planet to be measured, or till they respectively
two stars, the angle between which is to be deter
The symmetrical separation of the edges is produce
measured by a single screw; the fractions of a revo
of the screw are obtained by an index attached to on
of the screw, reading on a dial divided into 100
parts. The whole arrangement is elegant and inge
A steel cylinder (about the thickness of a goose-
which forms the micrometer screw, has two thread
upon it, one-half being cut with a thread double the

steed, in the first volume of the *Historia Cœlesti*
inserted a series of measurements made by Gasc
extending from 1638 to 1643. These include the m
distances of some of the stars in the Pleiades, a few ob
tions of the apparent diameter of the sun, others
distance of the moon from neighbouring stars, and a
number of measurements of the diameter of the moon
Bevis (*Phil. Trans.*, 1773, p. 190) also gives resu
measurements by Gascoigne of the diameters of the
Jupiter, Mars, and Venus with his micrometer.

Delambre gives[3] the following comparison between t
sults of Gascoigne's measurements of the sun's semi-dia
and the computed results from modern determination

			Gascoigne.	*Conn. d. Te*
October	25 (o.s.)	.....	16′ 11″ or 10″	16′ 10″
,,	31	,, ...	16′ 11″	16′ 11″
December	2	,, ...	16′ 24″	16′ 16″

Gascoigne, from his observations, deduces the gr
variation of the apparent diameter of the sun to be
according to the *Connaissance des Temps* it amou
32″·3.[3] These results prove the enormous advance att
in accuracy by Gascoigne, and his indisputable title t
credit of inventing the micrometer.

Huygens, in his *Systema Saturnium* (1659), des
a micrometer with which he determined the app

[2] is an astonishing accuracy when the difficulty of the objects
ered. Few persons can see with the naked eye—much less
—more than six stars of the Pleiades, although all the stars
by Maestlin have been seen with the naked eye by a few
ls of exceptional powers of eye-sight.

[3] Delambre, *Hist. Ast. Moderne*, vol. ii. p. 590.

diameters of the principal planets. He inserted a slip of metal, of variable breadth, at the focus of the telescope, and observed at what part it exactly covered the object under examination; knowing the focal length of the telescope and the width of the slip at the point observed, he thence deduced the apparent angular breadth of the object. The Marquis Malvasia in his *Ephemerides* (Bologna, 1662) describes a micrometer of his own invention. At the focus of his telescope he placed fine silver wires at right angles to each other, which, by their intersection, formed a network of small squares. The mutual distances of the intersecting wires he determined by counting, with the aid of a pendulum clock, the number of seconds required by an equatorial star to pass from web to web, while the telescope was adjusted so that the star ran parallel to the wires at right angles to those under investigation.[1] In the *Phil. Trans.*, 1667, No. 21, p. 373, Auzout gives the results of some measures of the diameter of the sun and moon made by himself, and this communication led to the letters of Mr Townley and Dr Bevis above referred to. The micrometer of Auzout and Picard was provided with silk fibres or silver wires instead of the edges of Gascoigne, but one of the silk fibres remained fixed while the other was moved by a screw. It is beyond doubt that Huygens independently discovered that an object placed in the common focus of the two lenses of a Kepler telescope appears as distinct and well defined as the image of a distant body; and the micrometers of Malvasia, Auzout, and Picard are the natural developments of this discovery. Gascoigne was killed at the battle of Marston Moor on the 2d July 1644, in the twenty fourth year of his age, and his untimely death was doubtless the cause that delayed the publication of a discovery which anticipated, by twenty years, the combined work of Huygens, Malvaison, Auzout, and Picard in the same direction.

As the powers of the telescope were gradually developed, it was found that the finest hairs or filaments of silk, or the thinnest silver wires that could be drawn, were much too thick for the refined purposes of the astronomer, as they entirely obliterated the image of a star in the more powerful telescopes. To obviate this difficulty Professor Felice Fontana of Florence (*Saggio del real gabinetto di fisica e di storia naturale*, 1755) first proposed the use of spider webs in micrometers,[2] but it was not till the attention of Troughton had been directed to the subject by Rittenhouse that the idea was carried into practice.[3] In 1813 Wollaston proposed fine platinum wires, prepared by surrounding a platinum wire with a cylinder of silver, and drawing out the cylinder with its platinum axis into a fine wire.[4] The surrounding silver was then dissolved by nitric acid, and a platinum wire of extreme fineness remained. But experience soon proved the superiority of the spider web; its perfection of shape, its lightness and elasticity, have led to its universal adoption.

Beyond the introduction of the spider line it is unnecessary to mention the various steps by which the Gascoigne micrometer assumed the modern forms now in use, or to describe in detail the suggestions of Hooke,[5] Wren, Smeaton, Cassini, Bradley, Maskelyne, Herschel, Arago, Pearson, Bessel, Struve, Dawes, &c., or the successive productions of the great artists Ramsden, Troughton, Fraunhofer, Ertel, Simms, Cooke, Grubb, Clarke, and Repsold. It will be sufficient to describe those forms with which the most important work has been done, or which have survived the tests of time and experience.

Before astronomical telescopes were mounted parallactically, the measurement of position angles was seldom attempted. Indeed in those days, the difficulties attached to such measures, and to the measurement of distances with the filar micrometer, were exceedingly great, and must have taxed to the utmost the skill and patience of the observer. For, on account of the diurnal motion, the direction of the axis of the telescope when directed to a star is always changing, so that, to follow a star with an altazimuth mounting the observer requires to move continuously the two handles which give slow motion in altitude and azimuth.

Sir William Herschel was the first astronomer who measured position angles, the instrument he employed is described in *Phil. Trans.*, 1781, vol. lxxi. p. 500. It was used by him in his earliest observations of double stars (1779-83); but, even in his matchless hands, the measurements were comparatively crude, because of the difficulties he had to encounter from the want of a parallactic mounting. In the case of close double stars he estimated the distance in terms of the disk of the components. For the measurement of wider stars he invented his lamp micrometer, in which the components of a double star observed with the right eye were made to coincide with two lucid points placed 10 feet from the left eye. The distance of the lucid points was the tangent of the magnified angles subtended by the stars to a radius of 10 feet. This angle, therefore, divided by the magnifying power of the telescope gives the real angular distance of the centres of a double star. With a power of 460 the scale was a quarter of an inch for every second.

The Modern Filar Micrometer.

When equatorial mountings for telescopes became more general no filar micrometer was considered complete which was not fitted with a position circle.[6] The use of the spider line or filar micrometer became universal, the methods of illumination were improved; and micrometers with screws of previously unheard-of fineness and accuracy were produced. These facilities, coupled with the wide and fascinating field of research opened up by Sir William Herschel's discovery of the binary character of double stars, gave an impulse to micrometric research which has continued unabated to the present time. A still further facility was given to the use of the filar micrometer by the introduction of clock work, which caused the telescope automatically to follow the diurnal motion of a star, and left the observer's hands entirely at liberty.[7]

The modern filar micrometer has now assumed forms of five types.

Type A.—Micrometers in which there are two webs, each movable by a fine screw with a divided head. This is the usual English form of filar micrometer.

Type B.—Micrometers in which one web is movable by means of a fine screw with a divided head, and the other by a screw without a divided head. The latter screw, in ordinary use, is only employed to change the coincidence reading of the two webs, for eliminating the errors of the micrometer screw. This is the ordinary German form of micrometer as originally made by Fraunhofer and since by Merz, and employed by the Struves and other principal Continental astronomers down to the present day.

Type C.—A similar form of micrometer to B, except that the coincidence-point cannot be changed,—there being no second screw to alter the position of the fixed web.

Type D.—A micrometer somewhat similar in general construction to form B, except that, in addition to means of changing the zero point, there is a screw head by which a fine movement can be given to the whole micrometer box, in the direction of the axis of the micrometer screw. This is the modern form of micrometer as constructed by Repsold.

Type E.—Micrometers fitted with two eye-pieces for measuring angles larger than the field of view of an ordinary eye-piece.

The micrometer of type A is due to Troughton; it is represented in figs. 1, 2, 3. Fig. 1 is a horizontal section in the direction of the axis of the telescope. The eye-piece *ab* consists of two plano-convex lenses *a*, *b*, of nearly the same focal length, and with the two

---

[1] *Mém. Acad. des Sciences*, 1717, p. 78 *sq.*

[2] In 1782 (*Phil. Trans.*, vol. lxxii. p. 163) Sir W. Herschel writes:—"I have in vain attempted to find lines sufficiently thin to extend them across the centres of the stars, so that their thickness might be neglected." It is a matter of regret that Fontana's suggestion was unknown to him.

[3] Quekett in his *Treatise on the Microscope* ascribes to Ramsden the practical introduction of the spider web in micrometers. The evidence appears to be in favour of Troughton.

[4] *Phil. Trans.*, 1813, pp. 114-118.

[5] Dr Hooke made the important improvement on Gascoigne's micrometer of substituting parallel *hairs* for the parallel edges of its original construction (Hooke's *Posthumous Works*, p. 497).

[6] Herschel and South (*Phil. Trans.*, 1824, part iii. p. 10) claim that the micrometer by Troughton, fitted to their 5 feet equatorial telescope, is the first position micrometer constructed capable of measuring position angles to 1′ of arc.

[7] So far as we can ascertain the first telescope of large size driven by clockwork was the 9 inch equatorial made for Struve at Dorpat by Fraunhofer; it was completed in 1825. The original idea appears to be due to Passement (*Mém. Acad.*, Paris, 1746). In 1757 he presented a telescope to the king, so accurately driven by clockwork that it would follow a star all night long.

sides facing each other. They are placed at a distance apart n the focal length of *o*, so that the wires of the micrometer, nust be distinctly seen, are beyond *b*. The eye piece slides e tube *cd*, which screws into the brass ring *cl*, through nings in which the oblong frame, containing the micrometer passes. These slides are shown in fig. 2, and consist of rks *k* and *l*, into which the ends of the screws *o* and *p* are fitted. The slides are accurately fitted so as to have no lateral shake, but yet so as to move easily in the direction greatest length of the micrometer box. Motion is communi- the forks by female screws tapped in the heads *m* and *n*

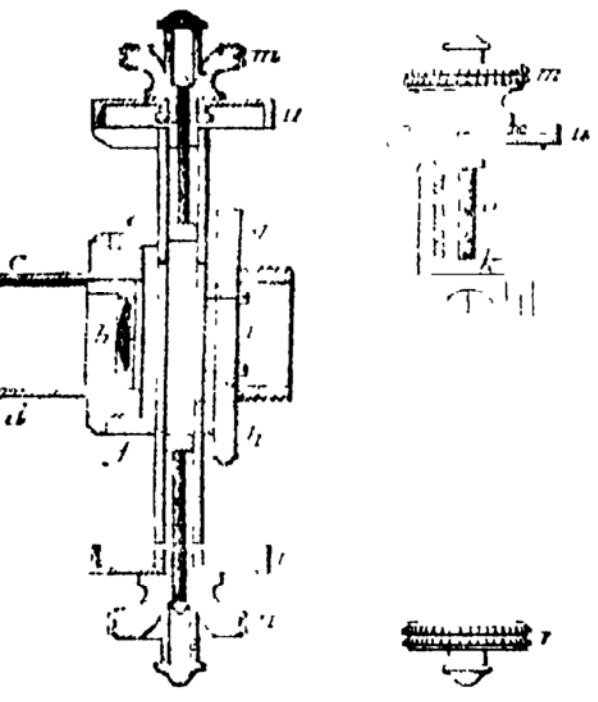

Fig. 1.

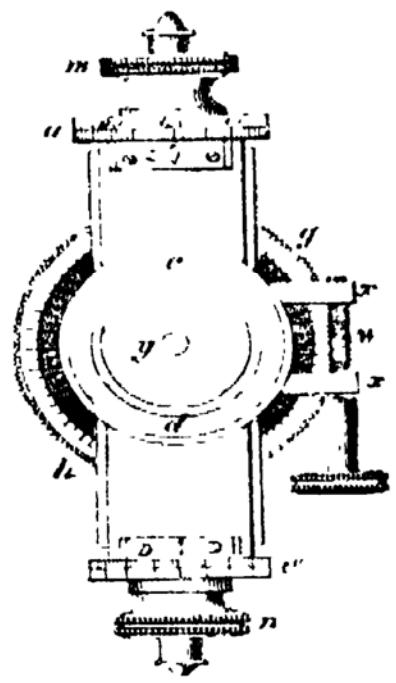
Fig. 3



on the screws *o* and *p* respectively. Two pins *a*, *a*, with springs coiled round them, pass loosely through holes in the *l*, and keep the bearings of the heads *m* and *n* firmly against the ends of the micrometer box. Thus the smallest of either head communicates to the corresponding slide mo- nch, if the screws are accurate, is proportional to the amount which the head is turned. Each head is graduated into al parts on the drums *r* and *s*, so that, by estimation, the can easily be carried to $\frac{1}{1000}$th of a revolution. The total of revolutions is read off by a scale attached to the side of but not seen in the figure.

spider webs are stretched across the forks, one (*v*) being d in a fine groove cut in the inner fork *k*, the other (*w*) in a groove cut in the outer fork *l*. These grooves are simultane- t *in situ* by the maker, with the end of an engine capable fine straight line, so that the webs when accurately laid rooves are perfectly parallel. A wire *xx* is stretched across re of the field, perpendicular to the parallel wires. Each web must pass the other without coming in contact with fixed wire, and without rubbing on any part of the brass. Should either fault occur (technically called "fiddling") it o accurate measurement. One of the most essential points od micrometers is that all the webs shall be so nearly in the ne as to be well in focus together under the highest powers d at the same time absolutely free from "fiddling." For ng position angles a brass circle *qh* (fig. 3, fixed to the tele- the screw *z*, has rack teeth on its circumference that receive n of an endless screw *w*, which, being fixed by the arms *xx* blong box *mn*, gives the latter a motion of rotation round of the telescope, an index upon this box points out on uated circle *m* the angular rotation of the instrument

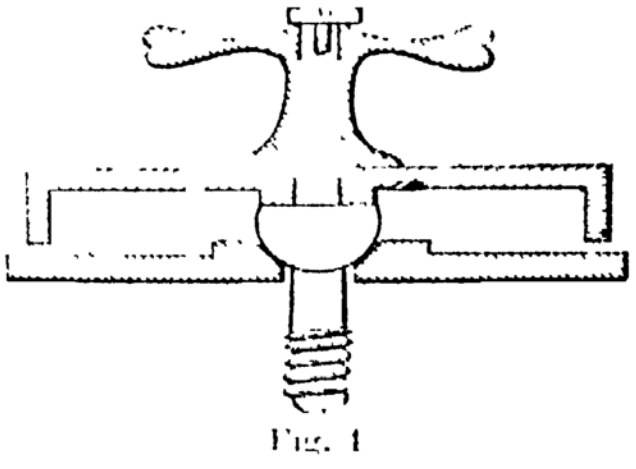


Fig. 4

ngle micrometer still be essential feature of on's general construc- ove described. The English artists have ot changed the mode communicating motion to les, by attaching the permanently to th eter head and tappin crometer screw into . Instead of making ulder of the screw a ing surface, they have e screw a spherical bearing resting in a hollow cone (fig. ed to the end of the box. The French artists still retain on's form. Simms, Troughton's successors, and Cooke (of or symmetry and more effectual elimination of "the loss of alled by the Germans "todter Gang," and sometimes in "back-lash"), have provided two pins with spiral springs, like *q* and *r* (fig. 2), one on each side of the screw which each slide.

Grubb of Dublin, with the intention of avoiding the vari pressure exerted by the spiral springs when the slide is at distances from the head of the screw, has adopted the following plan. Where the screw enters the slide he has a nut *n* attached to a strong spring *pp* (fig. 5), the pressure of which exerts a constant tension in the axis of the screw, tending to bring the threads into close contact, in opposite directions, with their bearings in the nut *n* and the slide *q*. The pressure of this spring is regulated by the screws *s*, *s*, tapped into the thickened ends of the springs. For maintaining the spherical shoulder of the screw in close and constant pressure on its conical bearing he has attached a conical bearing to the spring *p'p'* (fig. 6). The pressure of this on the upper part of the spherical shoulder is regulated by the screws *s'*, *s'*, passing through elongated holes in the spring *p'p'*, and tapped into the end of the box.

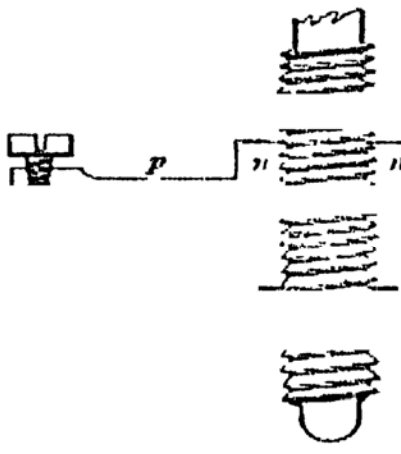

Fig. 5.

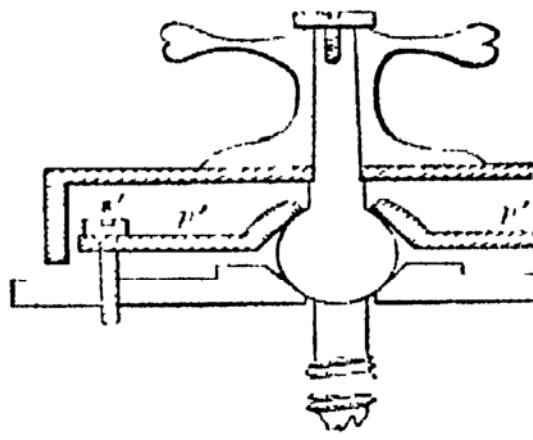

Fig. 6.

The screws of micrometers are generally made with 50 threads to the inch. Troughton's method of reading the of whole revolutions by a silver scale is inconvenient, becau or even $\frac{1}{50}$th of an inch is too small a quantity to read eas the naked eye, especially with the faint illumination t desirable to use when measuring faint objects. Different r including the "comb" (see below) and various kinds of "co have been introduced with more or less success; but rece Repsolds of Hamburg have contrived a plan at once so ample and so efficient that it will be unnecessary to describe those methods which this plan is certain to supersede (see below, type D). Grubb has introduced a modification in the form of the slides with a view to avoid the friction of one slide aga other. On the inner side of the brass plate which forms the of the box *cc*, the side opposite to the eye-piece) four V furrows are placed (fig. 7); and at each end of the slides junctions (fig. 8, end view) which fit into these furrows. T are kept down in their places by springs attached to them press upon the inner side of the lid of the box.

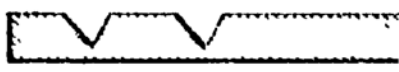

Fig. 7.

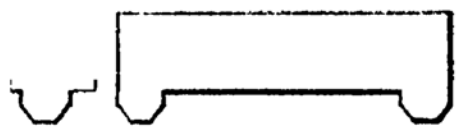

Fig. 8.

Troughton's mode of giving rotation to the position circl abandoned. A much quicker motion in position angle t be obtained without slow motion is often desirable, s observing very close double stars, the uncertainty of each ing may amount to several degrees in the most accurate ments. The plan of a pinion working in a toothed v often employed, but that also is too slow. Most moder meters are now fitted with a clamp and slow motion screw 9, type B). This permits observation of position angles close objects by simple rotation of the box with the hand; w slow motion, after clamping, permits the more delicate mo that are required in measuring the position angle of objects apart.

The Cookes and Grubb have for years almost invariab ferred the position circle from the micrometer to the telesco The whole eye-end with its focussing arrangements rotates, rotation can be measured by a circle attached to the but the tube. There is considerable convenience in this arran One position circle only is required for all the micromet may be employed with the instrument; and the orient reticulated diaphragms, or the adjustment of the directio slit of a spectroscope, may also be accomplished by the sam But, after a very extended experience of all the various existing mountings, the present writer does not hesitate to decided preference for a position circle attached to the micro a rigid attachment of the eye-end to the telescope tube,—havi seen an eye-end attached to a position circle on the butt e telescope-tube in which, after the wear and tear of a fe

, is known as Ramsden's eye-piece, it was made originally by him.

some looseness or shake could not be detected. This is a fatal fault, especially in those delicate observations of difference of declination which have latterly formed so prominent a feature in refined micrometric research. On the other hand, in some good old micrometers at the Royal Observatory, Cape of Good Hope, that are fitted with attached position circles, there is no trace of shake or wear after fifty years of work.

The micrometer of type B represented in fig. 9[1] is the original Merz micrometer of the Cape Observatory, made on Fraunhofer's model. S is the head of the micrometer screw proper, s that of the screw moving the slide to which the so-called "fixed web" is attached, *s'* that of a screw which moves the eye-piece E. C is the clamp and M the slow motion in position angle. L, L are tubes attached to a larger tube N; the latter fits loosely on a strong hollow cylinder which terminates in the screw V. By this screw the whole apparatus is attached to the telescope. The

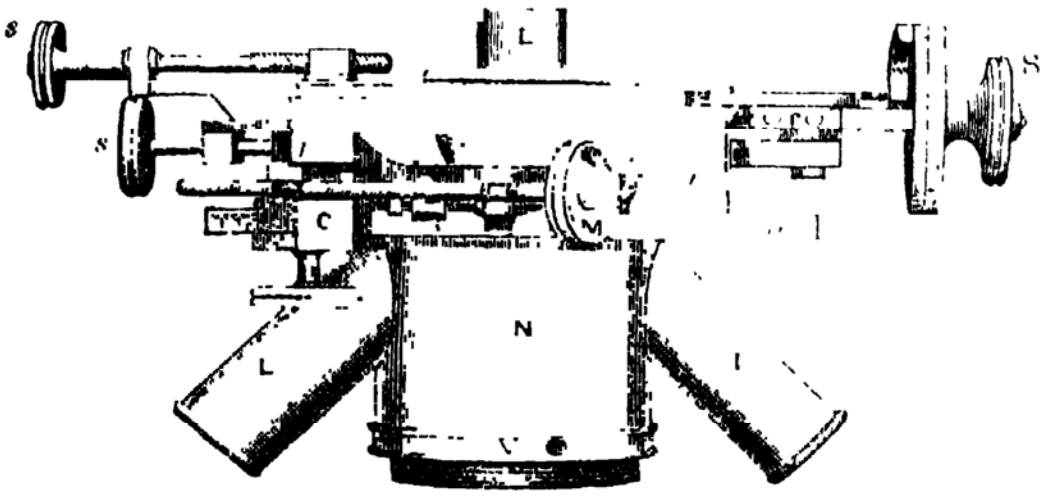

Fig. 9.

nozzles of small lamps are inserted in the tubes L, L, for illuminating the webs in a dark field; the light from the lamps is admitted through apertures in the strong hollow cylinder above mentioned (for illumination, see below). In this micrometer the three slides moved by S, *s*, and *s'* are simple dovetail. The lowest of these slides reposes upon a foundation-plate *pp*, into one end of which the screw *s* is tapped. In the middle of this slide a stiffly fitting brass disk is inserted, to which a small turn-table motion may be communicated by an attached arm, acted on by two fine opposing screws accessible to the astronomer; and by their means the "fixed wire" may be rendered strictly parallel with the movable wire.

The micrometer screw is mounted on the slide which carries the movable web. Fig. 10 shows a plan of this slide; the divided drum of the screw is omitted for sake of clearness. The screw S has a shoulder at *κ*, carefully fitted and ground to a bearing so as to work sweetly in a hole in the very strong spring *σσ*; the other extremity of the screw is formed into a pivot, which fits a hole in the brass piece *ββ*. The end of this pivot, hardened, polished, and slightly rounded—rests on the flat surface of an agate *a*, which is imbedded in the end of the slide, and kept firmly in its place by the brass piece *ββ*. By careful adjustment of the screws *θ*, *θ* sufficient pressure may be left upon *κ* to slightly bend the strong spring *σσ* and thus eliminate all end-shake without preventing easy action of the screw. The screw passes at the same time through the bush B (shown in plan and elevation, fig. 10) attached to *pp* (fig. 9); and there is a fine saw cut, which can be narrowed by the small screw *τ*, to close the bush upon the micrometer screw with a view of preventing "loss of time." The spider web *ω* is cemented on the further side of the thin plate *νννν*, the varnish being applied in the countersunk holes shown by the dotted circles *μ*, *μ*. The slide is countersunk to about half its thickness within the area indicated by *oooo*, in order to allow the adapter of the eye-piece to come sufficiently close to the webs. The eye-piece was originally moved by a pinion working in a rack *r* (fig. 9); but the screw *s'* applied by Simms was found by Maclear to be more convenient for the purpose. Beyond this, and the graduation of the edge of the circle with more strongly cut divisions than those originally engraved on the face of the circle, the instrument remains and is figured in its original form. Pistor and Martius (Berlin) have also made excellent instruments of the above type. There is a celebrated micrometer of their make, with which, in the hands of Brunnow at Dunsink (Dublin), some of the most perfect and refined investigations ever made in practical

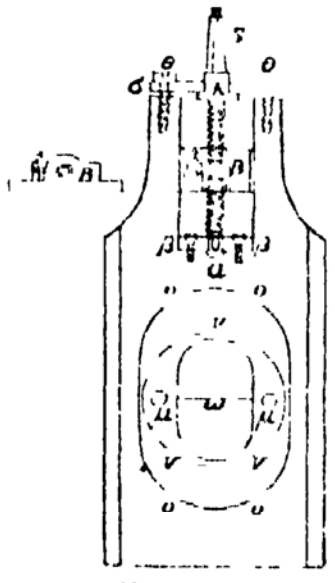

Fig. 10.

[1] When it is remembered that the measurements of the Struves, Dembowski, Secchi, the Bonds, Maclear, and of most modern Continental astronomers have been made with Fraunhofer or Merz micrometers, it is not too much to say that fig. 9 represents the instrument with which three-fourths of the astronomical measurements of the last fifty years have been made.

astronomy have been executed. In this micrometer the screw s mounted on its own slide and has a divided head precisely l the screw S (fig. 9). The plate *pp* is elongated towards s, and corresponding bush B is attached to this elongation. The screw is shifted to another part of the eye-piece slide, so that it does interfere with the increased diameter of the screw *s*. Fraunhofer micrometer in this form belongs to type A, but is quoted un type B for convenience of description.

It is not necessary to give a figure representing type C. Su micrometers have been generally constructed on Troughton's ty (figs. 1, 2, 3) with the omission of one of the screws, and w one or more of the modifications described in detail under type Some have also been made similar otherwise to the Fraunhofer c struction, by omitting the screw *s* with its corresponding sl and attaching the fixed wire to a circular plate in *pp*.

Good instruments have been made on type C by Clark (Cambrid Massachusetts), by Stemheil (Munich), and by the great Fren artists Secretan, Froment, Brunner, Eichens; and good work has be done with them. But it is necessary that the errors of the scr should be very carefully determined, since, in type C, such erro cannot be eliminated by employing different parts of the screw measure the same angle. There is a noteworthy description micrometer that forms a link between types C and D, of which t most famous example (by Clark) is attached to the great Washin ton telescope. It is essentially a micrometer of type C, with a sli (or fork) and a screw of the English form of construction. But t instrument is provided with a screw as at *s* (fig. 9), which, inste of changing the position of the fixed wire, moves the whole micr meter box in the direction of the axis of the measuring-screw. Th the fixed wire can be set exactly on one star by the screw *s* wh the other star is immediately afterwards bisected by the moval wire, and that without disturbing the reading for correction of the wires. No one, unless he has previously worked with such an arrangement, can fully appreciate the advantage of bri ing up a star to bisection by the fixed wire by moving the microme box with a delicate screw motion, instead of having to change t direction of the axis of a huge telescope for the same purpo When it is further remembered that the earlier telescopes were provided with the modern slow motions in right ascension, a that the Struves, in their gigantic labours among the double sta used to complete their bisections on the fixed wire by a pressure the finger on the side of the tube, one is puzzled whether most wonder at the poor adaptation of means to ends or the marvell patience and skill which, with such means, led to such results." should be added that Dawes practically adopted a modification Clark's micrometer by using a slipping piece, and bolting one the heads of his micrometer (*Mem. R. A. S.*, vol. xxxv. p. 13 His slipping piece gave motion to the micrometer by two slid one in right ascension the other in declination, so that "either the webs can be placed upon either of the components of a doub star with ease and certainty."

All micrometers used, in conjunction with a micro-scope, for re ing the divisions of transit circles, heliometer scales, &c., are of t type C. The reading micrometer is shown in fig. 11. C is t objective, D the micrometer box, E the gra nated head of the screw, G the milled he by which the screw *c* is turned, A an ey piece sliding in a tube B, *aa* (fig. 12) the sli

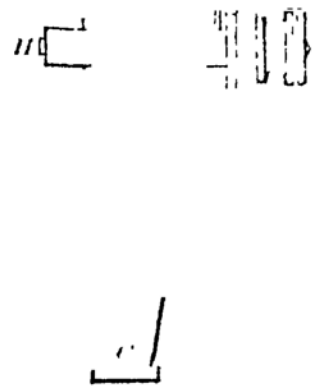

Fig. 11.

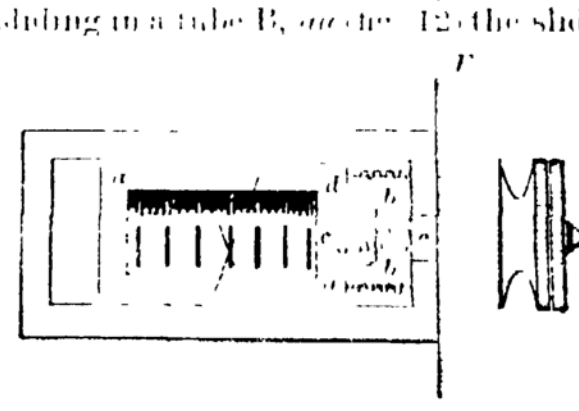

Fig. 12.

and *b*, *b* the spiral springs. The focal length of the objec and the distance between the optical centre of the lens and webs are so arranged that images of the divisions are formed the plane of the webs, and the pitch of the screw is such that division of the scale corresponds with some whole number of volutions of the screw.

There is what is technically called a "comb" inserted in t micrometer box at *d* (fig. 12),- its upper surface being nearly in plane of the wires. This comb does not move with reference to box, and serves to indicate the whole revolution of which a fracti is read on the head. In fig. 12 a division is represented bisected cross webs, and five revolutions of the screw correspond with division of the scale. In all modern reading micrometers the cr webs of fig. 12 are replaced by parallel webs embracing the divis

[2] The late Professor Watson used to say quaintly and with truth, "After the best part of the micrometer is the man at the small end!"

g. 13). The means for changing the length of the tube and the stance of C from the scale are omitted in the figure. These appli-nces are required if the "run" has to be accurately ljusted. By "run" is meant the difference between the ntended whole number of screw-revolutions and the etual measure of the space between two adjacent di-isions of the scale in turns of the screw divided by the umber of intended revolutions. In delicate researches wo divisions of the scale should always be read, not merely for increased accuracy but to obtain the corrections for "run" from the observations themselv

Fig. 13.

Fig. 14 represents an important type of reading micrometer by the Repsolds. Here the web-frame r mounted on the screw itself The muting plane of motion is at p, where the end of the micrometer crew bears upon the hardened flattened end of the screw s, and is ept in bearing against this plane by the spiral spring q Rotation

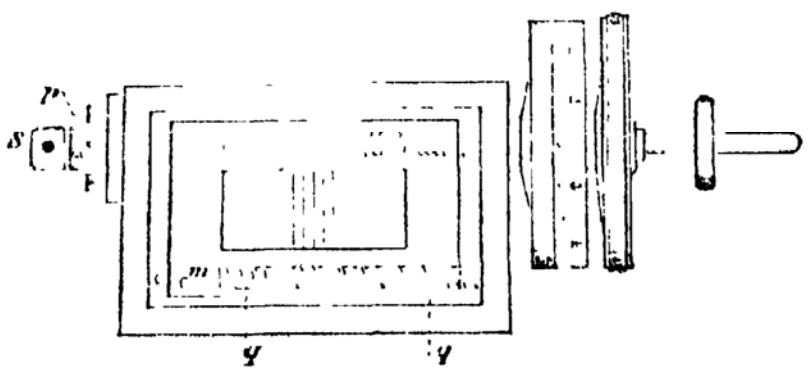

Fig. 14.

f the wire-frame is prevented by the small stud m which passes nough the web frame and projects slightly on both sides of it, st barely touching the inner surfaces of the top and bottom of the icrometer box. The web-frame thus rests solely on the screw and n the point m, and therefore follows it absolutely and accurately.

The comparative merits of the various micrometers are discussed y Lord Lindsay and Mr Gill (*Dunecht Publications*, vol. ii. pp. 3–55, 1877). If the screw of the Repsold micrometer is bent, so hat, for example, the end of the frame next the screw head is raised nd that next the end p lowered, a twist will be given to the web-ame, and the centre of the wire will be moved nearer to the micro-eter head than it should be, while the reverse effect will follow when he head has been turned through 180°. The effect of a similar rror on the other micrometers described would be of a much less mount. They are, however, liable to errors of another character , as in Troughton's original micrometer, the shoulder is square, he hole in the end of the box may be left sufficiently wide to allow or a small error in the parallelism of the screw matrix with the otion of the slide, but the smallest bend in the screw causes the houlder no longer to bear flat, but to ride on its edge, thus intro-ucing an extremely uncertain form of error. If the shoulder is pherical, fitting into a hollow cone on the end of the box, as in the icrometers of Simms, Cooke, and Grubb, an almost inconceivable ccuracy of construction is implied in drilling the matrix of the crew in the slide so that its axis and that of the cone shall be in he same straight line, and both parallel to the motion of a point n the slide. Any departure from perfect accuracy in this respect as the effect of bringing different portions of the spherical boulder o bear on different parts of the cone for different revolutions, and ntroduces errors of a character by no means easy to deal with. In ddition to these objections there always is the greater objection f employing as a delicate contact-measuring surface one that is xposed where oil is used. Dust and oil will arrange themselves in ayers of variable and uncertain thickness and defeat all attempts o secure absolutely consistent results. In Repsold's micrometer he *point d'appui* is a small hardened and polished bearing, requir-ng little lubrication, and perfectly protected from dust, the errors f the screw (some of them exaggerated, certainly) are faithfully eproduced, and consequently determinable, and beyond this the ork to be done by the screw is reduced to a minimum,—no slide-iction having to be overcome. If we are to regard as the most erfect instrument, "not that which has absolutely the smallest rrors, but that which reproduces its errors with the most perfect onsistency," undoubtedly Repsold's form of micrometer is best.

In order to avoid the examination of the screw-errors produced y the non-symmetrical portion of the screw in Repsold's micro-eter, Stone, in December 1879, exhibited at the Royal Astronomical ociety, and described (*Monthly Notices*, p. 240), a modification of epsold's instrument. But, both in his statement of the comparative erits of the Troughton and Repsold micrometers and in the ew form which he figures, Stone overlooks a strong point in the Rep-old form, and in that proposed by Lord Lindsay and Gill three years reviously,[1]—namely, the avoidance of all friction of the slide, and he elimination of all error or strain that may occur from a want of arallelism in the axis of the matrix and the motion of the slide. he Lindsay-Gill micrometer will be better understood from the ollowing description. In fig. 15 Ss is the micrometer screw, its

[1] *Dunecht Publications*, vol. ii., footnote p. 55, Dunecht, 1877.

cylindrical axis is nicely ground to fit a hole in the side of the box at a;[2] the same axis, but ground to a somewhat smaller cylinder, fits neatly but smoothly a hole in the web-frame at b. A screw, cut on the same axis, is tapped into the web-frame at s, and the axis terminates in a pivot which fits a hole in a brass plate cc. The end of the pivot—hardened and slightly rounded rests on a flat agate[3] bearing a, which is imbedded in the plate B, and securely held *in situ* by pressure of the plate cc. The plate B is firmly attached to the bottom of the box. q, q are spiral springs mounted on pins. Both springs and pin pass freely through the web-frame at p, p, and the pins (but not the springs) pass freely through the frame at n, n.[4] The parallel webs for observing the division (fig. 13) are mounted on the forked end of the frame at ww.

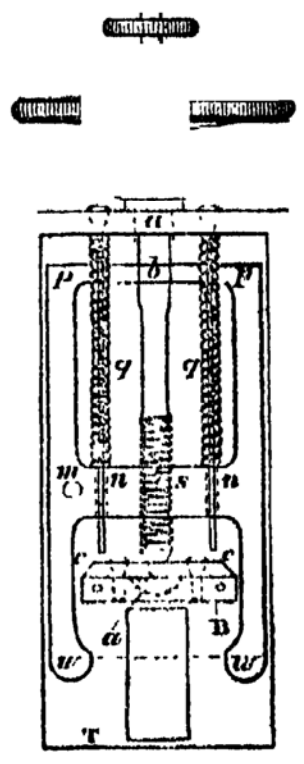

Fig. 15.

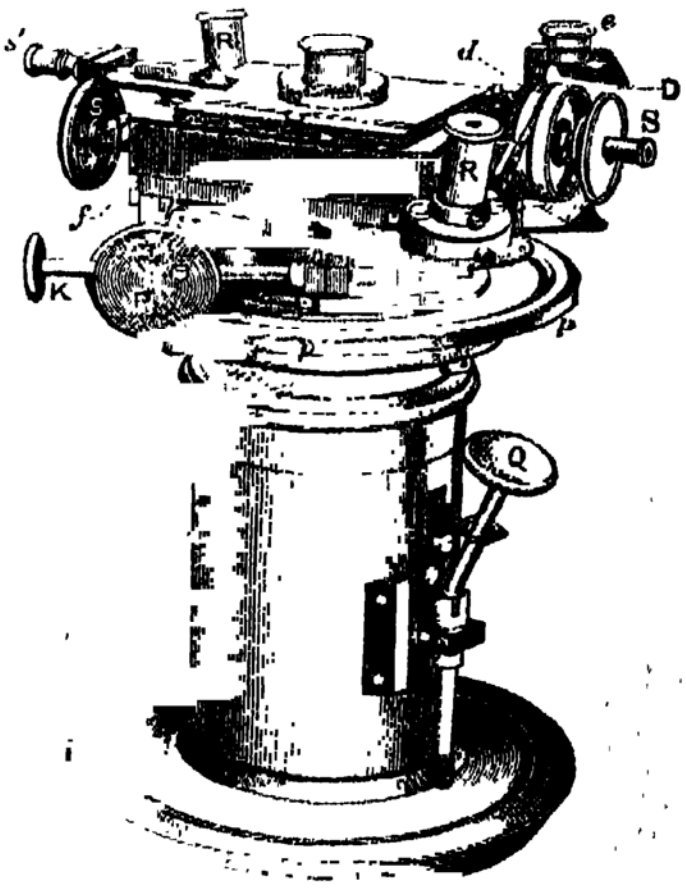
The web-frame is narrower and thinner than the breadth and height of the interior of the box, and is only prevented from rotating by the delicate touch of the projecting ends of the pin m on the inner surfaces of the top and bottom of the box. It appears that a frame so mounted fulfils all theoretical conditions of accuracy. It is perfectly free to follow the motion of the screw and accurately to reproduce its errors, notwithstanding any reasonable faults of workmanship; and no permissible shake or fouling of the bearing at a can produce sensible error in the distance between the bearing surface of the agate plane and the spider webs. The motion is produced with the minimum of friction; and the "feel" of the screw is therefore as delicate and perfect as it is possible to make it.

The micrometer of type D shown in fig. 16 has recently been made by the Repsolds for the Cape Observatory. As this instrument combines all their most recent modifications, we describe it in detail. Fig. 17 represents the same micrometer with the upper side of the box removed. The letters in the description refer to both figures.



S is the head of the micrometer screw, s that of the screw by which the micrometer box is moved relative to the plate f (fig. 16), s' that of the screw which moves the eye-piece slide. K is the clamp in position angle, P the slow motion screw in position angle; pp is the position circle, R, R its two readers. The latter are in fact little microscopes carrying a vernier etched on glass, in lieu of a filar micrometer. These verniers can be read to 1′, and estimated to 0′·2. D is the drum-head which gives the fraction of a revolution, d that which gives the whole number of revolutions, I is the index or pointer at which both drums are read. This index is shown in fig. 17, but only its mode of attachment (X, fig. 17) in fig. 16. The teeth of the pinion z, fig. 17, are cut on the axis of the micrometer screw. The drum d and its attached toothed wheel are ground to turn smoothly on the axis of the screw. The pinion z and the toothed wheel d are connected by an intermediate wheel and pinion Y; the numbers of teeth in the wheels and pinions are so proportioned that twenty-four revolutions of the micrometer screw produce one revolution of the drum and wheel d. (This is the description of Repsold's counter referred to under type A.) The divisions of both drums are conveniently read, simultaneously, by

[2] There would be some advantage in allowing the screw's axis to pass with a little shake through the hole in the end of the box at a, and then, extending the length of the larger cylinder, transfer the bearing from a to a well-fitting hole in a piece fixed like B to the bottom of the box. This form would also give some facilities of construction, and all the oiled surfaces would be perfectly protected.

[3] Sapphire is better; the agate bearing of such a screw has been found very sensibly worn.

[4] If it is desired to prevent possible contact of these pins with the frame, the ends of the pins may be made to enter guiding holes in cc.

the lens e; at night the lamp which illuminates the webs and the position circle also illuminates the drum-heads (see on illumination below). $\alpha\alpha\alpha\alpha$ is the web-frame (fig. 17), $\beta\gamma$ is a single rod consisting of two cylinders accurately fitting in the ends of the micrometer box, the larger cylinder being at β. There is a hole in the web-frame which smoothly fits the larger cylinder at β', and another which similarly fits the smaller cylinder at γ'. A spiral spring, coiled round the cylinder γ, resting one end on the shoulder formed by the difference of the diameters of the cylinders β and γ and the other on the inside of the web-frame, presses the latter continuously towards γ. Contact of the web-frame of the micrometer with the side of the box at γ would therefore take place, were it not for the micrometer screw. This screw fits neatly in the end of the box at ϵ, passes loosely through the web frame at ϵ', is tapped into the frame at ζ', and its end rests on a flat hardened surface at ζ. Rotation of the web-frame about $\beta\gamma$ is prevented by the heads of the screws at m; the head of the screw on the lower side of the frame reposes on the plane $\nu\nu$, that on the upper side (fig. 17) touches lightly on the inner surface of the lid of the box. Such rotation can obviously be controlled within limits that need not be further considered. But freedom of rotation in the plane of the paper

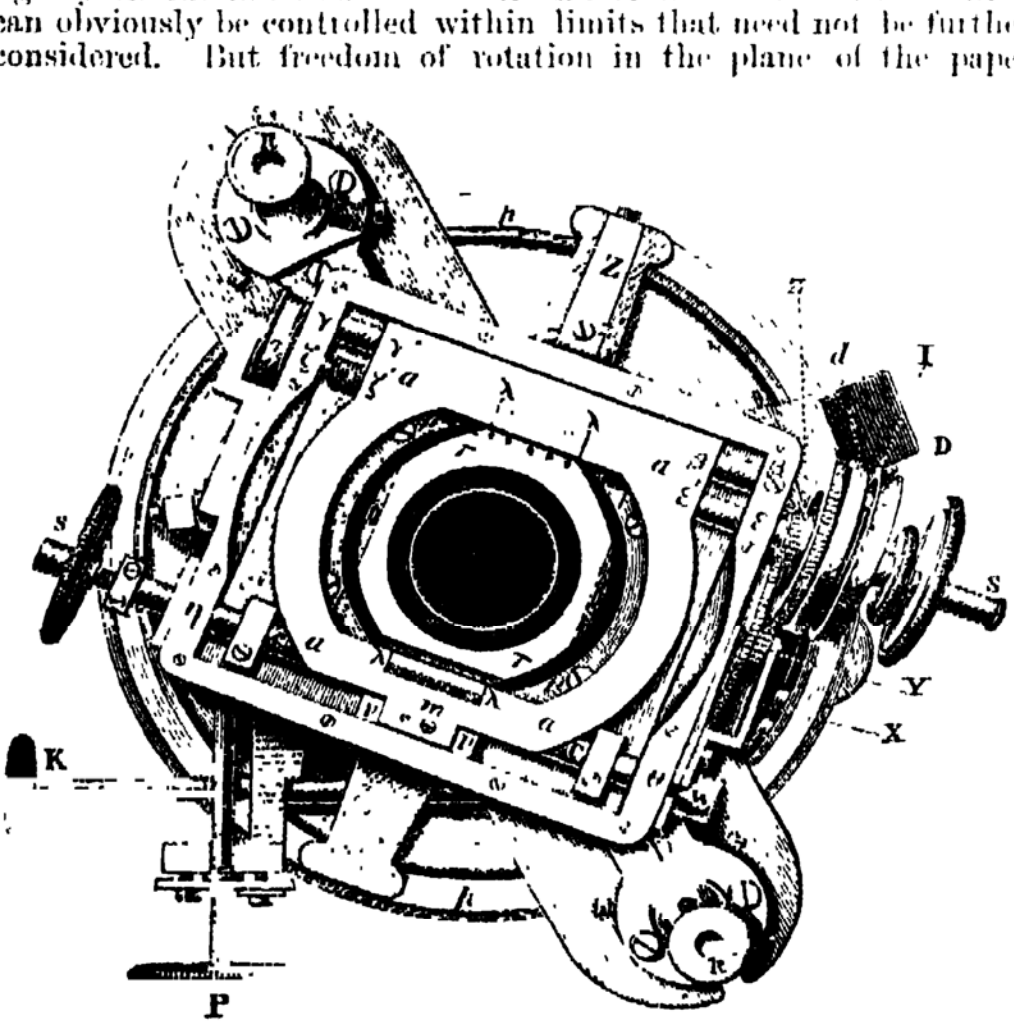


Fig. 17.

(fig. 17) is only prevented by good fitting of the holes β', γ'; and, since the weight of the slide is on one side of the screw, misfit here will have the effect of changing the reading for coincidence of the movable with the fixed web in reverse positions of the micrometer. With the Cape micrometer a systematic difference has been found in the coincidence point for head above and head below amounting to 0″·14. This corresponds, in the Cape instrument, with an excess of the diameters of the holes over those of the cylinders of about $\frac{1}{1000}$th of an inch,—a quantity so small as to imply good workmanship, though it involves a systematic error which is very much larger than the probable error of a single determination of the coincidence point. The obvious remedy is to make all measures on opposite sides of the fixed web before reversing in position angle,—a precaution, however, which no careful observer would neglect. In measuring differences of declination, where the stars are brought up by the diurnal motion, this precaution cannot be adopted, because it is necessary always to bisect the preceding star with the fixed web. But in $\Delta\delta$ measures index error can always be eliminated by bisecting both stars with the same web (or different webs of known interval fixed on the same frame), and not employing the fixed web at all. Had the spring q been placed as in fig. 14, and the cylinders β and γ been made to bear like the pivots of a transit on segmental bearings in the frame at β' and γ', it is probable that the difference in coincidence points would not have existed. Such a modification appears advisable, unless this construction, by leaving the end m less free, should make the "feel" of the screw less sweet and perfect. The discordance in zero when known to exist is really of no consequence, because the observations can be so arranged as to eliminate it.

The box is mounted on a strong hollow steel cylinder CC (fig. 17) by holes η, θ in the ends of the box, which fit the cylinder closely and smoothly. The cylinder is rigidly fixed in the studs C, C, and these are attached to the foundation plate f. The cylinder contains towards η a sliding rod, and towards θ a compressed spiral spring. There is thus a thrust outwards of the spring upon the hollow cap W (attached outside the box), and a thrust of the rod upon the end of the screw s. The position of the box relative to the plate f, in the direction of measurement, depends therefore on the distance between the end of the screw s and the fixed stud C. A screwing in of s thus causes the box to move to the left, and *vice versâ*. Rotation of the box round CC is prevented by downward pressure of the spring Z on a projection attached to the side of the box. The amount of this pressure is regulated by the screw z.

The short screw whose divided milled head is σ shifts the zero of the micrometer by pushing, without turning, the short sliding rod whose flat end forms the *point d'appui* of the micrometer screw at ζ. The pitch of the screw σ is the same as that of the measuring screw (50 threads to the inch), and its motion can be limited by a stop to half a revolution.

The five fixed webs are attached to the table $\tau\tau$, which is secured to the bottom of the box by the screws ρ. The three movable webs are attached to the projections $\lambda\lambda$ on the frame $\alpha\alpha$. The plane surfaces $\tau\tau$ and $\lambda\lambda$ are composed of a bronze of very close texture which appears capable of receiving a finish having almost the truth and polish of an optical surface. It seems also to take a very clean V cut, as the webs can be laid in their furrows with an astonishing ease and precision. These furrows have apparently been cut *in situ* with a very accurate engine, for not the slightest departure from parallelism can be detected in any of the movable webs relative to the fixed webs. Extraordinary care has evidently been bestowed in adjusting the parallelism and distance of the planes τ and λ, so that the movable wires shall almost, but not quite, touch the surface τ. The varnish to fix the webs is applied, not on the surface τ as is usual, but on a bevel for the purpose,[1] the position of the webs depending on their tension to keep them in their furrows. The result is that no trace of "fiddling" exists, and the movable and fixed webs come sharply together in focus with the highest powers. Under such powers the webs can be brought into apparent contact with such precision and delicacy that the uncertainty of measurement seems to be as much in the estimation of the fraction of the division of the head as in the accuracy of the contact. It is a convenient feature in Repsold's micrometer that the webs are very near the inner surface of the top of the box, so that the eye is not brought inconveniently close to the plate when high powers are used.

Micrometers of the type E have been invented by Alvan Clark and Grubb. Clark's micrometer was exhibited at the June meeting of the Royal Astronomical Society in 1859 (*Monthly Notices R. A. S.* vol. xix.). It is capable of measuring angles up to about one degree. It is "furnished with two eye-pieces, composed of small single lenses, mounted in separate frames, which slide in a groove and can be separated to the required distance. A frame carrying two parallel spider lines, each mounted separately with its own micrometer screw, slides in a dovetailed groove in front of the eye pieces, and by a free motion in this frame each web can be brought opposite its own eye-len- In using this micrometer, the first step is to set the position-vernier to the approximate position of the objects to be measured. Then the eye-lenses are separated till each is opposite its own object. The frame containing the webs and their micrometer screws is then slid into its place; and the webs, having been separated nearly to their proper distance by their free motion in the frame, are placed precisely on the objects by their fine screws, the observer's eye being carried rapidly from one eye-lens to the other a few times, till he is satisfied of the bisection of each of the objects by its own web. The frame is then removed for reading off the measure by means of an achromatic microscope, on the stage of which it is placed." The advantages which Clark claims are these:

"1. Distances can be observed with great accuracy up to about one degree, and the angles of position also.

"2. The webs, being in the same plane, are perfectly free from parallax, and are both equally distinct, however high the magnifying power may be.

"3. The webs are also free from distortion and from colour.

"4. A different magnifying power may be used on each of the objects,—which may be advantageous in comparing a faint comet with a star."

It appears to us that the method of removing a slide in order to measure the interval between the webs is liable to objection, not only because of the risk to the webs, but because the taking of measurements of such a different character with a different instrument is inconvenient and troublesome. It is true that the intervals between the webs could be measured by an assistant, and two or more different slides be employed to save time; but astronomers will probably generally prefer the method introduced by Grubb described below. It is understood that Clark has since improved this instrument by an ingenious arrangement of prisms which permits both webs, even though separated one degree in a large telescope, to be seen in the same eye piece. The arrangement is not described, and is said to be, as yet, somewhat troublesome to arrange previous to measurement, though when arranged it gives very good results.

Grubb (*Scientific Proceedings of Royal Dublin Society*) thus describe

[1] The marks of varnish so applied will be seen in fig. 17

hat he calls his "duplex micrometer," shown in perspective in fig. :—"A plate of glass about 2½ inches square is ruled with twenty-ne lines in one direction $\frac{1}{10}$th inch apart, and two lines in the other rection 2 inches apart. The extreme lines of the set therefore rm a perfect square of 2 inches. These lines are ruled with xceeding accuracy and care, but provision is left for ascertaining ny errors that remain either as to distance or want of perfect quareness. Along ne side of the square mounted a micro-eter frame in the rdinary way, actu-ted by a screw of ne hundred thread o the inch. The icrometer frame carries eleven line orresponding exact to each alternate ne in the gla eticule, so that when e first spider line made coincident ith the first dia-ond line on the lass the last spider

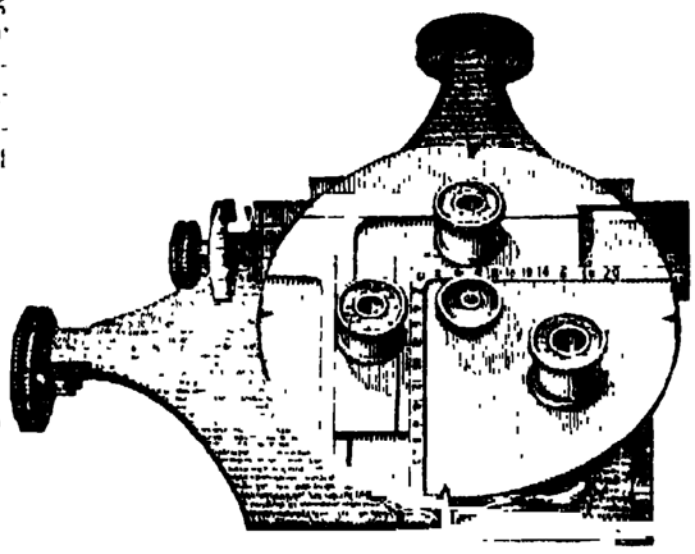

Fig. 18.

ne will be coincident with the last line on the glass, and each of e spider lines will be coincident with all the odd numbers of iamond lines, 1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21. Over this glass late is placed a brass cap in which two eye-pieces are mounted, ne sliding in a groove at right angles to the other, so that, hile one has its journey backwards and forwards on the horizontal ne, the other has its journey on the vertical line, according to ow the cap is placed, for this cap is capable of rotation to meet arious circumstances.

"*How to Use the Instrument.*—1. The two stars are brought on the orizontal line, and the distance measured from centre to centre long that line. This distance is measured by counting the number spaces on the glass, adding the residue as measured by the icrometer screw. Thus the screw is never used for larger measures an $\frac{1}{10}$th inch, and therefore errors of screw and temperature errors e much reduced. In bisecting, one star is brought into the field one eye-piece, and a bisection is made with one of the diamond ne—by moving the micrometer by one or other of its slipping piece rews. Then the other eye-piece is moved till the second star is en, and a bisection is made with the nearest spider line by moving e micrometer head. Then the eye can be moved back to the first ye-piece, and the bisection checked, and again back to the other ye-piece. When it is seen that both are satisfactory the measure n be read off. 2. The micrometer is turned round till the orizontal line becomes parallel to the path of apparent motion of e star. This is easily found by stopping the clock and allowing e star to run along the horizontal wire. Now the other star will e found to cross the vertical line somewhere, while the first star is n the horizontal line. This second star is then bisected on the ertical line, while the first star is bisected by one of the spider nes; thus the difference in right ascension is found. We then ave two sides of a right-angled triangle, and of course all the lements are known.

"*To Investigate the Errors arising out of the Distance of the Lines.*—Of course the usual plan of taking transits can be adopted, and to ascertain if the lines be perpendicular at right angles a special additional ye-piece is provided so that transits can be taken across each iagonal of the square."

This instrument has great advantage over Clark's in case of djustment not true, and has done good work at the University Observatory, Oxford (*Mon. R. A. S.*, vol. xlvii. pp. 5, 12). Professor Pritchard claims too much when he estimates its work as qual in accuracy with that of the heliometer—at least the published esults do not contain such a view. But it is a very valuable nstrument for measuring objects too faint for the limited aperture of most heliometers, and which at the same time are farther apart han the field of view of its micrometer eye-piece.

The accuracy of the duplex micrometer would be very greatly ncreased if Clark's idea above mentioned, of viewing both widely eparated wires in one eye-piece of high power could be reduced to convenient practical form.

Method of Webbing the Eye Micrometer.

The webbing of a micrometer is a process that should be familiar o all practical astronomers. English opticians usually proceed as ollows. A spider (the variety is marked by a cross on the back, nd is found in English gardens about decayed wood) is caught, nd placed on a wire fork. The insect immediately attaches a web o the wire and begins to lower itself by a web to the ground. This web is wound up on the fork till ten or twelve turns, separated by convenient space, have been secured. A brush with varnish is then passed along the prongs; the webs are thus securely fixed to the fork. The parallel prongs of the fork must be sufficiently far apart to allow the web frame of the micrometer to pass between them. The frame to be webbed is placed on a flat dull black surface between the prongs of the fork, the latter being carefully arranged so that one of the webs lies nearly in the furrow ruled in the frame for its reception. As the web-frame is generally thicker than the fork, the web will now be stretched across the former, with a certain amount of tension, and is brought into the furrow with a finely pointed piece of soft wood. If the surface of the frame is well polished, and the furrows sharply cut, without "burr," the web should leap sharply and decidedly into its place. Each end of the web is then secured by a drop of shellac varnish, which should be allowed to harden thoroughly before the frame is touched. The webs can be very readily so handled against a black background, with the aid of a hand lens of 2 or 3 inches focus. In experienced hands this method gives good results, but the following, which is generally followed on the Continent, is preferable.

A web, about 2 inches longer than the width of the frame, is unwound from a cocoon,[1] and small pieces of lead are attached to its extremities by beeswax. One end of the web, with its attached lead, is laid on a piece of cork floating in a tumbler of water; the other end is allowed to hang down in the water, where it becomes thoroughly saturated and untwisted. It is then laid across the fork, and dropped into its furrows in the manner above described, the little lead weights exerting a definite tension. Varnish[2] is immediately applied to secure the webs, and the frame is not touched till it is dry.

The bevel-edge of the web-frame introduced by Repsold (type D) offers great facilities for accurate webbing, and should be employed in all future micrometers.

Illumination of Micrometers.

When micrometer observations are made by night it is necessary to have some mode of rendering the webs visible, either by rays of light at right angles to the axis illuminating the webs, or by rays nearly coincident with the axis of the telescope. In the former case we get bright webs in a dark field, in the latter dark webs on a bright field.

In the older telescopes bright web illumination is produced by small lamps with nozzles that enter the tubes L, L (fig. 9). The illumination is regulated in colour and intensity by wedges of coloured or darkened glass passing through slides in the nozzles. But it is inconvenient to have lamps so near the observer's eye, and it is at least very difficult to obtain a perfectly dark field when the wires are illuminated in this way.

The Clarks, in their micrometer of the great Washington telescope, have made the end of box T (fig. 15) transparent, and light is thrown on the webs from a lamp held by an assistant. Holden has very recently applied a lamp ingeniously hung so as to preserve its verticality and the constant direction of its light in a similar way, adding a plain silvered mirror inside the box and opposite the lamp, so as to illuminate the webs symmetrically. In the Clarks' and Holden's methods it is only the webs at right angles to the screw that are illuminated.

For illumination of the field, in very old telescopes, light was thrown on a small ivory reflector fixed outside the object-glass in the axis of the telescope by an arm fitting on the cell of the lens. This involved the aid of an assistant to direct lamplight on the ivory reflector, or the very frequent change of a lamp support. Afterwards the light from an attached lamp was introduced through a hole in the telescope-tube and thrown upon an elliptical plane (generally dull-gilt) having its centre part cut away sufficiently to avoid interruption of the cone of rays from the object glass. Many ingenious modes of suspending the lamp have been invented for the purpose of securing a constant direction of its light coupled with verticality of the lamp. One of the best of these, due to Cooke, is shown in fig. 19. L is the lamp, P a prism to reflect

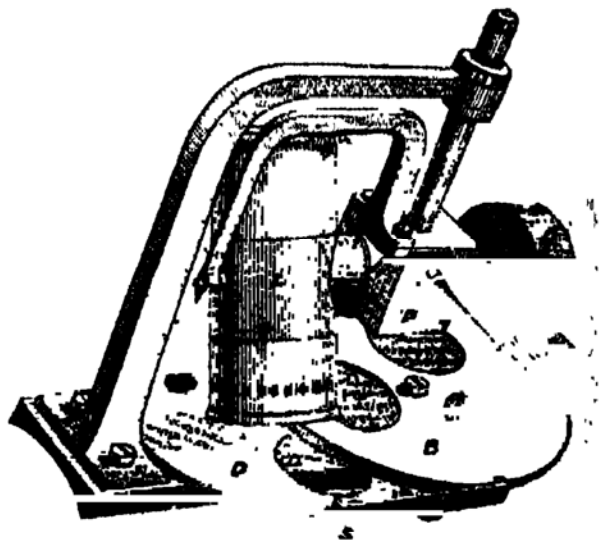

Fig. 19.

[1] It is asserted that webs from cocoons are more elastic, better shaped, and more durable than those obtained during an effort of the insect to escape. The best webs we have seen were from a cocoon obtained in Holland, but we have been unable to ascertain the name of the variety of spider.

[2] Argelander used to apply two drops of varnish at each end of his webs. He first fixed each extremity by a drop of shellac varnish, and after that had dried he applied a drop of copal varnish nearer the centre of the frame; the latter took a long time to harden, but gave ultimately a much stronger attachment.

nto the tube, D a disk to regulate the quantity of light, k with glasses to regulate the colour of the light, S a o clamp the disks, C the counterpose of the lamp, G a preserve the horizontality of the axis CL. But astronomers the genius of Grubb the introduction of a more efficient vement system, viz., the performance of all necessary illu- n of an astronomical telescope by a single lamp, and the ontrol of the illumination of the field or webs, and the n of these as to intensity or colour by simple motions from nd. It is impossible to speak too highly of Grubb's efforts irection; he has broken the ground in this department of nical engineering, and rendered the working of so huge an ent as the Vienna telescope of 27 inches aperture not only nt, but easier for a single observer than that of a very lescope of the older constructions.

the illumination of the field wires and scales of micro- Grubb's original method has recently been surpassed by h is due to the Repsolds. We shall therefore describe the

of the ring causes the four slides to approach or recede from When the handle *p'* is in the middle of its range, the ether form a disk as large as the hole in the diaphragm *dd*, prevent all light from entering the telescope tube. When ed to one side of its range the slides move outwards leaving opening in the centre so that the light falls on the prism *n*, whence it is diverted to a silvered reflector cemented on the middle of the inner surface of the object-glass, and is then reflected back along the axis of the telescope to illuminate the field at *a*. When *p'* is pushed to the other side of its range the slides again overlap at the centre, excluding light from *n* and allowing it to fall upon the reflector *s* instead. From *s* the light is thrown upon the webs *ω*, *ω* by reflexion from a white papier maché surface lined on the inside of a thin hollow brass truncated cone *xx*. The edge of this cone forms the circle seen within *rr* in fig. 17. All stray light is prevented by the light-guard tube *mm*, which is attached to and moves with the rotating part of the micrometer. The result is to produce a symmetrical illumination of the whole system of webs on a perfectly dark field. It is also obvious that by placing *p'* at any intermediate position between the centre and the extremes of its range any desired modification of bright wire or bright field illumination can be obtained at pleasure.

The light falling on the papier maché hollow cone is intercepted at three points by prisms, one of which *w* is shown in section. These prisms are inserted in the cylinder which carries the foundation plate of the micrometer box and rotate with it. Two of them divert light upon the reflectors *s* seen from different points of view in figs. 16, 17, 20. The third prism after two reflexions (fig. 16, 20) illuminates the micrometer head. The whole arrangement is in the highest degree elegant, and we have found it most simple and convenient in practice. The screen C (figs. 20 and 21) made of thin copper and attached to AB effectually protects the observer's eye from stray light from the lamp.

It has been found essential, in bright field illumination, when the highest accuracy is desired, to have the illuminating rays parallel with the telescope axis.

In the best telescopes of the future some plan like that of Repsold's, above described, will doubtless be adopted. It is probable also that with the introduction of condensers, in connection with the incandescent carbon light in vacuum, electricity will ultimately supersede the oil or paraffin lamp in illuminating astronomical instruments. A small "Swan lamp" can be placed anywhere, is unaffected by wind, and gives off comparatively little heat. These are most valuable qualities for the purpose in question.

The astronomer-royal (Mr Christie) has recently used luminous paint to render the measuring pointer of the Greenwich spectroscope viewable at night. This paint, after exposure during the day to sunlight, shines at night with a dull phosphorescence sufficient to make the micrometer pointer, to which it is applied, faintly visible, and it is stated, with very satisfactory result.

On the use of the five micrometer consult Struve, *Mensura Micrometrica*, St Petersburg, 1837, Brunnow *Practical and Spherical Astronomy*, Chauvenet *Practical and Spherical Astronomy*, Brunnow, *Astronomical Observations and Researches made at Dunsink*, Dublin 1860, 1870, 1879. Bessel *Astr. Beobachtungen*; and the papers of Dembowski in the *Memorie de Venezia*.

Double Image Micrometers.

The discovery of the method of making measures by double images is stated to have been first suggested by Roemer about 1678. But no such suggestion occurs in the *Basis Astronomiae* of Horrebow (Copenhagen, 1735), which contains the only works of Roemer that remain to us. It would appear that to Savary is due the first invention of a micrometer for measurement by double image. His heliometer (described in a paper communicated to the Royal Society in 1743, and printed, along with a letter from Short, in *Phil. Trans.*, 1753, p. 156) was constructed by cutting from a complete lens *abcd* the equal portions *agbe* and *cgfe* (fig. 22). The segments *abk* and *cfd* so formed were then attached to the end of a tube having an internal diameter represented by the dotted circle (fig. 23). The width of each of the portions *agbe* and *cgfe* cut away from the lens was made slightly greater than the focal length of lens = tangent of sun's greatest diameter. Thus at the focus two images of the sun were formed nearly in contact as in fig. 24. The small interval between the adjacent limbs was then measured with a wire micrometer.

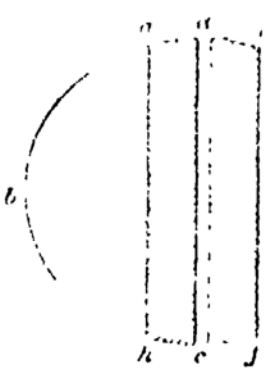

Fig. 22.

Fig. 23.

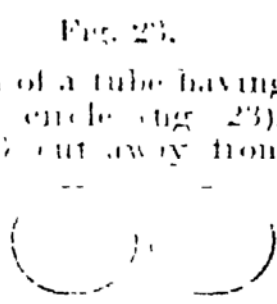

Fig. 24.

Savary also describes another form of heliometer, on the same principle, in which the segments *agbe* and *cgfe* are utilized by cementing their edges *gh* and *ef* together (fig. 25) and covering all except the portion indicated by the unshaded circle. Savary expresses preference for this second plan, and makes the pertinent remark that in both these models "the rays of red light in the two solar images will be next to each other, which will render the sun's disk more easy to be observed than the violet ones. This

e mentions "because the glasses in the two sorts are somewhat
nsmatical, but mostly those of the first model which could
n before bear no great charge" of magnifying power.

A third model proposed by Savary consisted of two complete
enses of equal focal length, mounted in cylinders
de by side, and attached to a strong brass plate be-
ig. 26). Here, in order to fulfil the purposes of the pre-
ious models, the distance of the centre of the lenses
om each other should only slightly exceed the tan-
ent of one diameter to focal length of lens.
avary dwells on the difficulty both of procuring
enses sufficiently equal in focal length and of accurately
djusting and centring them.

In the *Mem. de l'Acad. des Sciences*, 1748, Bouguer des-
ribes an instrument which he calls a héliomètre
alitude in his *Traité d'Optique* (p. 139) he mentions
uch a héliomètre which had been in his possession
rom the year 1729, and of which he gives a representation on
Plate XXVIII. fig. 3 of the same volume. Bouguer's héliomètre was at first similar to that of Savary's
third model, with the important difference that the two object-glasses being
fixed, one of them is movable by a screw
moved by a divided head. No auxiliary
eye-glass or micrometer was required, as in
Savary's héliomètre to measure the interval
between the limbs of two adjacent images
of the sun it became only necessary to turn
the screw with the divided head to change
the distance between the object-glasses till
the two images of the sun are in contact as
in fig. 27. The differences of the readings
of the screw which corresponded to one afford
the means of measuring the variation of
the sun's apparent diameter.

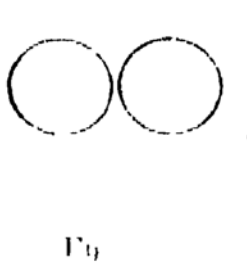

Fig. 25.

Fig. 26.

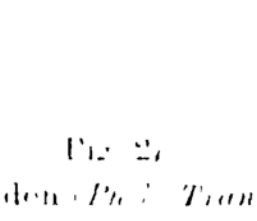

Fig. 27.

On the 4th April 1754 Dollond communicated a paper to the Royal Society of London (*Phil. Trans.*, vol. xlviii. p. 567) in which he shows that a micrometer can be much more easily constructed by dividing a single object-glass through its axis than by the employment of two object-glasses. He points out also that a telescope with an object-glass so divided still produces a single image of any object to which it may be directed, provided that the optical centre of the segments are in coincidence; and provided the segments retain their same relative positions to each other as before the glass was cut; so that if the segments are separated in any direction two images of the object viewed will be produced. So that the most convenient direction of separation for micrometric purposes is to slide these straight edges one along the other as the figure in the margin (fig. 28) represents them: "for thus they may be moved without suffering any false light to come in between them, and by this way of removing them the distance between their centres may be very conveniently measured, viz., by having a vernier's division fixed to the brass work that holds one segment, to slide above a scale on the plate to which the other part of the glass is fitted.

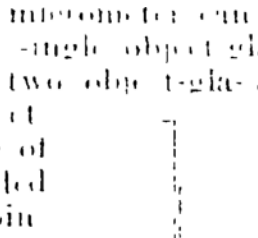

Fig. 28.

Dollond then points out three different types in which a glass so divided and mounted may be used as a micrometer.

"1. It may be fixed at the end of a tube, of a suitable length to its focal distance, as an object-glass, the other end of the tube having an eye-glass such as is usual in astronomical telescopes.

"2. It may be applied to the end of a tube much shorter than its focal distance, by having another convex glass within the tube, to shorten the focal distance of that which is cut in two.

"3. It may be applied to the open end of a reflecting telescope, either of the Newtonian or the Cassegrain construction."

Dollond adds his opinion that the third type is "much the best and most convenient of the three", yet it is the first type that has survived the test of time and experience, and which is in fact the modern héliomètre.

Fig. 29 illustrates Dollond's divided object-glass héliomètre of the third type. A is the end of the reflecting telescope, upon which the adapter B is fitted. B carries a wheel (not seen in the figure) formed of a ring racked at the outer edge, and fixed to the brass plate CC, so that a pinion moved by the handle D may turn it into any position. Two plates F, G, with the attached semi-lenses, move in slides fixed to the plate CC, a simultaneous motion, in contrary directions, being communicated to them by turning the handle E, which drives a concealed pinion that works in the two racks seen in the highest part of the figure. The amount of separation of the semi-lenses is measured by a scale 5 inches long, subdivided to $\frac{1}{10}$th of an inch, and read by a vernier on the plate F to $\frac{1}{100}$th of an inch. In practical use this micrometer has never given satisfactory results (see Mosotti in the *Efemeride* of Milan for 1821). It must be remembered, however, that when Dollond gave preference to this type he had not *invented* the achromatic object-glass; his preference was fully justified under these circumstances. So far as we know no héliometer with a divided achromatic object-glass was ever made by the elder Dollond on the principle of his first type. His son, however, made what he called an "elder" micrometer, which was a great improvement on the elder Dollond's second type.

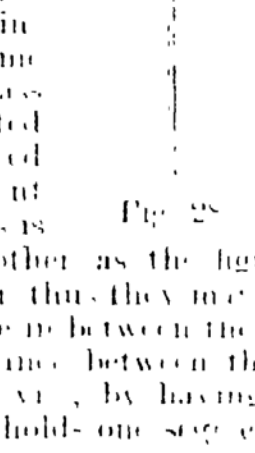

Fig. 29.

In the older construction the brass mountings of the semi-lenses obstructed the light entering the telescope in proportion to their separation, and the images were so coloured as to prevent the use of any but very low powers. In the later construction the movable segments are formed from a negative achromatic lens of much larger aperture than the object-glass of the telescope with which the micrometer is employed, and, for convenience in mounting, the segments *abh* and *cdi* (fig. 22) are removed. In the fine example of this instrument at the Royal Observatory, Cape of Good Hope, the movable lenses consist of segments of the shape *gach* and *cacf* (fig. 22) cut from a complete negative achromatic combination of 8¼ inches aperture and about 41 feet focal length, composed of a double concave flint lens and a double convex crown. This is applied to an excellent achromatic telescope of 3¼ inches aperture and 12 inches focal length. The instrument is represented in fig. 30, the same letters indicate the analogous parts of fig. 29. The frame CC moved by teeth on its outer edge, carries one of the lenses G of the lens, and a similar frame with teeth carries the other half F. A scale 8¼ inches long is fastened like an edge-bar to the frame of the segment G, and each inch is subdivided into twenty parts, which are read off by a vernier to $\frac{1}{1000}$th of an inch, and, by estimation, this can easily be carried to $\frac{1}{5000}$th or $\frac{1}{4000}$th of an inch. The two movable frames are imbedded in a fixed plate HH, screwed to the adapter B having a circular hole in its middle equal to the diameter of the object-glass. The slide of the segment G is moved by turning the milled head to the right of A, and the other segment F by means of a rack and pinion on the opposite side, the latter being turned from the eye-end by a handle not seen in the figure. A screw is provided for clamping the slide of the segment G, as it is intended that only the segment F shall be moved in making the final bisection. There is an index attached to the slide of G, reading on a rough scale engraved on the plate H, which is obviously intended for setting the optical centre of the segment G approximately as far from the optical axis of the telescope on one side as the optical centre of the segment F will be on the other side during the intended measurement. This arrangement not only permits the measurement of angles twice as great as would be possible if one segment were fixed, but is also important in increasing the symmetry of the measures. The vernier is placed at one end of the scale when the optical centres of the segments are in coincidence, and is provided with screws at I, which are intended for adjusting the zero of the scale. The younger Dollond has in this model retrograded, in some respects, from the admirable example of his father, who, as shown in fig. 29, not only gave the lenses automatic opposite motion symmetrically with respect to the axis of the telescope, but seems also to have provided for entire elimination of index error by making it possible to observe all angles on opposite sides of zero—a precaution possible in the later form only when very small angles are measured. Rotation of the micrometer in position angle is provided for as in the earlier form, but the instrument is not furnished with a position circle.

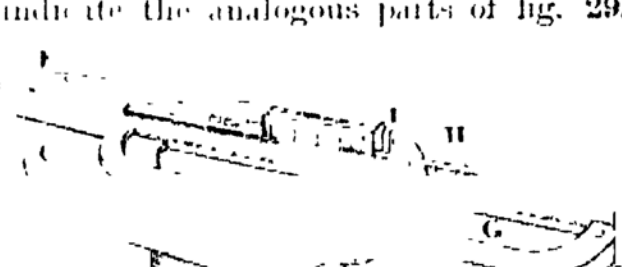

Fig. 30.

With one of these instruments of somewhat smaller dimensions (telescope 2½ inches aperture and 3½ feet focus) Triesnecker made a series of measurements at the observatory of Vienna which has been recently reduced by Dr Schur of Strasburg (*Nova Acta der Ksl. Leop. Carol. Deutschen Akademie der Naturforscher*, xlv. No. 3). The angle between the stars ζ and *g* Ursæ maj. (708″·55) was measured on four nights; the probable error of a measure on one night was ± 0″·44. Jupiter was measured on eleven nights in the months of June and July 1794; from these measures Schur derives the values 35″·39 and 37″·94 for the polar and equatorial diameters respectively, at mean distance, corresponding with a compression 1/14·44. These agree satisfactorily with the corresponding value

35″·21, 37″·60, 1/15·69 afterwards obtained by Bessel (*Konigsberger Beobachtungen*, xix. 102). From a series of measures of the angle between Jupiter's satellites and the planet, made in June and July 1794 and in August and September 1795, Schur finds the mass of Jupiter $= \frac{1}{1018.55 \pm 1.45}$, a result which accords perfectly with the received value of the mass derived from modern researches. The probable errors for the measures of one night are ±0″·547, ±0″·889, ±0″·542, ±1″·096, for Satellites I., II., III., and IV. respectively. It is probable that Tiesnecker deduced the index error from his measures of the diameter of Jupiter, and in 1794, the measures of diameter are made on the same nights with those of the measures of distance of the satellites, and it is possible that measures of diameter may have been made in 1795 but not published.

Considering the accuracy of these measures (an accuracy far surpassing that of any contemporary [illegible] somewhat surprising that the form of micrometer was never systematically used in any sustained or important astronomical researches, although a number of instruments of the kind were made by Dollond. Probably the first example of its employment is in observation of the transit of Mercury (November 4, 1868) by Mr Main, at the Royal Observatory, Cape of Good Hope (*Monthly Notices R. A. S.*, vol. xxix. p. 197–209). The most important part, however, which this type of instrument seems to have played in the history of astronomy arises from the fact that one of them was in the possession of Bessel at Konigsberg during the time when his new observatory there was being built. In 1812 Bessel entered into correspondence with Fraunhofer (then almost exclusively engaged in Germany, were used by verniers only.

[illegible] angle between the components of the double star δ Cygni and observed the great comet of [illegible] of the disc of the sun on May 4, 1818. In the discussion of these observations (*Konigsberger Beobacht.*, Abth. 3, p. xv) he found that the index error of the scale changed systematically in different position angles by quantities which were independent of the direction of gravity, but depended solely on the direction of the micrometer relative to the axis of the object glass. Bessel attributed this to non-homogeneity in the object glass, and determined with great care the necessary corrections. But he was so delighted with the general performance of the instrument, with the sharpness of the images, and the possibilities which a kindred construction offered for the measurement of considerable angles with micrometric accuracy, that he resolved, when he should have the choice of a new telescope for the observatory, to secure some form of heliometer.

Nor is it difficult to imagine the probable course of reasoning which led Bessel to select the model of his new heliometer. Why, he might ask, should he not select the simple form of Dollond's first type? Given the achromatic object-glass, why should not it be divided? This construction would give all the advantage of the younger Dollond's object glass micrometer and more than its sharpness of definition, without liability to the systematic errors may be due to want of homogeneity of the object glasses, for the lenses will not be turned with respect to each other, but, in measurement, will always have the same relation in position angle to the line joining the objects under observation. It is true that the scale will require to be capable of being read with much greater accuracy than $\frac{1}{100}$th of an inch, for that, even in a telescope of 10 feet focus, would correspond with 2″ of arc. But, after all, this is no practical difficulty.—for screws can be used to separate the lenses, and, by these screws, as in a Gascoigne micrometer, the separation of the lenses can be measured, or we can have scales for this purpose, read by microscopes, like the Troughton[1] circles of Pond, or those of the Carey circle, with almost any required accuracy.

Whether Bessel communicated such a course of reasoning to Fraunhofer or whether that great artist arrived independently at like conclusions, we have been unable to ascertain with certainty. The fact remains that before 1820 Fraunhofer had completed one or more of the five heliometers (3 inches aperture and 39 inches focus) which have since become historical instruments. In 1821 the great Konigsberg heliometer was commenced, and it was completed in 1829.

To sum up briefly the history of the heliometer. The first application of the divided object glass and the employment of double images in astronomical measures is due to Savary in 1743. To Bouguer in 1748 is due the true conception of measurement by double image without the auxiliary and of a filar micrometer, viz., by changing the distance between two object glasses of equal focus. To Dollond in 1754 we owe the combination of Savary's idea of the divided object-glass with Bouguer's method of measurement, and the construction of the first really practical heliometers. To Fraunhofer, some time not long previous to 1820, is due, so far as we can ascertain, the construction of the first heliometer with an achromatic divided object-glass, *i.e.*, the first heliometer of modern type.

[1] The circles by Reichenbach, then almost exclusively used in Germany, were

[2] The diameter of Venus was measured with one of these heliometers at the observatory of Breslau by Brandes in 1820 (*Berlin Jahrbuch* 1824, p. 164).

Double-Image Micrometers with Decided Lenses.

Various micrometers have been invented besides the heliometer for measuring by double image. Ramsden's dioptric micrometer consists of a divided lens placed in the conjugate focus of the innermost lens of the erecting eye tube of a terrestrial telescope. The inventor claimed that it would supersede the heliometer, but it never done anything for astronomy. Dollond claims the independent invention and first construction of a similar instrument. Peters (*Practical Astronomy*, vol. ii. p. 182). Of these and kindred instruments only two types have proved of practical value. Amici of Modena (*Mem. Soc. Ital.*, xviii. (1816) pp. 344–359) describes a micrometer in which a negative lens is introduced between the eye piece and the object-glass. This lens, divided and mounted like a heliometer object glass, the separation of the lenses produces the required double image and is measured by a screw. Dawes has very successfully used this micrometer in conjunction with a filar micrometer, and finds that the precision of the measures in this way greatly increased (*Monthly Notices*, vol. xviii. p. 9, and *Mem. R. A. S.*, vol. xxxv. p. 117).

In the improved form[3] of Airy's divided eye-glass micrometer (*Mem. R. A. S.*, [illegible]09), the rays from the object-glass pass successively through lenses as follows:

1st lens	Concave lens	Focal length p
2nd lens	Achromatic convex lens	Arbitrary q
3rd lens	Eye-piece	r

The lens b is divided, [illegible] one of the [illegible] is moved by micrometer screw. The magnifying power is varied by changing the lens a for another in which p has [illegible] value. The magnifying power of the eye piece is that [illegible] of focus r.

In 1850 Airy pointed out that the other optical conditions could be equally satisfied if the divided lens were made concave instead of convex, with the advantage of giving a larger field of view (*Monthly Notices*, vol. x. p. 160).

The last improvement on this instrument is mentioned in the *Report* of the R. A. S. council February 1865. It consists in the introduction by Simms of a fifth lens, but no satisfactory description has [illegible]d. There is only one practical published investigation of Airy's micrometer that is worthy of mention, viz., that of Kaiser, *Annalen der Sternwarte zu Leiden*, iii. 111–174. The reader is referred to that paper for an exhaustive history and discussion of the instrument. It is somewhat surprising that, after Kaiser's investigations, observers should, as in time, as many have done, to discuss their observations with the instrument as at [illegible] screw value were constant for all an

Steinheil (*Journal Savant de Munich*, 28th February 1843) describes a "héliomètre-oculaire" which he made for the great Pulkowa refractor, the result of consultations between himself and the late Struve. It is essentially the same in principle as Amici's micrometer, except that the divided lens is an achromatic positive instead of a negative lens. Struve (*Description de l'Observatoire Central de Pulkowa*, pp. 196, 197) adds a few remarks to Steinheil's description, in which he states that the images have not all desirable precision, a fault perhaps inevitable in all micrometers with divided lenses, and which is probably in this case aggravated by the fact that the rays falling upon the divided lens have considerable convergence. He however, successfully employed the instrument in measuring double stars [illegible] 1″ or 2″, and using a power of 300 diameters, with results that agreed satisfactorily amongst themselves and with those obtained with the filar micrometer. If Struve had employed a properly proportioned dou

[3] For description of the earlier forms see *Cambridge Phil. Trans.*, vol. x. *Greenwich Observations*, 1849.

[4] We understand that a very thorough investigation of Airy's double micrometer used by De Opelard at Mauritius on Lord Lindsay's expedition has been made by him and will soon be published.

[5] Dawes (*Monthly Notices* January 1858, and *Mem. R. A. S.* vol. xxx. p. has suggested and used a valuable improvement for producing round images instead of the elongated images which are otherwise inevitable when the pas through a bevelled lens of which the optical centres are not in coincide [illegible], the introduction of a diaphragm having two circular apertures [illegible] line of collimation of the tel the diameter of each aperture [illegible] the semidiameter of the co rays at the distance of the diaphragm from the focal point of the object gl Practically the difficulty of making these diaphragms for the different powe the exact required equality is insuperable, but, if the observer is content to a certain amount of light, we see no reason why they may not readily be slightly less. Dawes found the best method for the purpose in question was limit the aperture of the object glass by a diaphragm between a double eye aperture, placing the line joining the centres of the circles approximately in position angle under measurement. Dawes successfully employed the double circular aperture also with Amici's micrometer. The present writer has successfully used a similar plan in measuring position angles of a Centauri with the heliometer, viz., by placing circular diaphragms on the two segments of the object glass.

ular diaphragm, fixed symmetrically with the axis of the telescope in front of the divided lens and turning with the micrometer, it is probable that his report on the instrument would have been still more favourable. The particular instrument had been fashioned to correct, having led Struve to some of those corrections of the Dorpat heliometer which ultimately bore such valuable fruit (see below).

Ramsden (*Phil. Trans.*, vol. xcv. p. 129) had suggested the division of the small speculum of a Gregorian telescope and the introduction of double motion by rotation of the semi-circles in the plane perpendicular to the axis. Brewster (*Encyc. Metrol.*, Sheet, vol. xiv. p. 749) proposed to act on a like principle, dividing the plane mirror of a Newtonian telescope. Again, to obtain an ocular heliometer by which a double image is similarly produced by a divided prism of total reflexion placed in parallel rays. But practically both of these methods are failures. In the latter the field is full of false light, and it is not possible to give sufficiently intimate and steady adjustment to the nearer pair of prisms of total reflexion, and a small telescope through which the rays must pass, consequently loses much of its light.

Micrometer depending on Double Refraction.

To the Abbé Rochon (*Journ. de Paris*, Jan., 1801, pp. 169, 198) is due the happy idea of applying the two images formed by double refraction to the construction of a micrometer. He fell upon a most ingenious plan of doubling the amount of double refraction of a prism by using two prisms of rock crystal, so cut out of the solid as to give each the same quantity of double refraction, and yet to double the quantity in the effect produced. The combination so formed is known as Rochon's prism. Such a prism to be placed between the object-glass and eye piece of a telescope. The separation of the images increases as the prism is approached to the object-glass, and diminishes as it is approached towards the eye-piece.

Arago (*Comptes Rendus*, xxiv., 1847, pp. 400, 402) found that a Rochon micrometer, when the prism was approached close to the eye piece for the measurement of very small angles, the smallest imperfections in the crystal or its surfaces were enormously magnified. He therefore selected for any particular measurement such a Rochon prism as when fixed between the eye and the eye piece (*i.e.*, where a sunshade is usually placed) would, combined with the normal eye piece employed, bring the images just to be measured nearly in contact. He then altered the magnifying power by sliding the field lens of the eye-piece (which was fitted with a slipping tube for the purpose) along the eye tube, till the images were brought into contact. By a scale attached to the sliding tube the magnifying power of the eye piece was deduced, and this combined with the angle of the prism employed gave the angle measured. If p'' is the refracting angle of the prism, and n the magnifying power of the eye piece, then $p'' n$ will be the distance observed. Arago made many measures of the diameters of the planets with such a micrometer.

Dollond (*Phil. Trans.*, 1821, pp. 101, 103) describes a double-image micrometer of his own invention in which a sphere of rock crystal is substituted for the eye lens of an ordinary eye-piece. In this instrument (figs. 31, 32) a is the sphere, placed in half axle, on

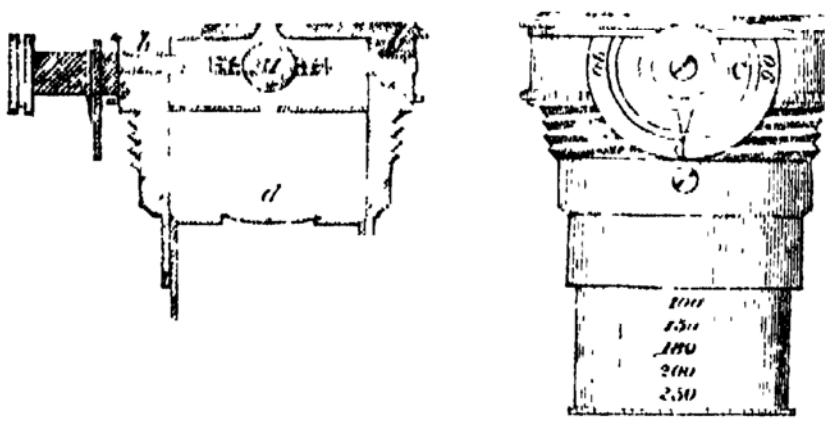

Fig. 32.

axis bb, so that when its principal axis is parallel to the axis of the telescope it gives only one image of the object. In a direction perpendicular to that axis it must be so placed that when it is moved by rotation of the axis bb the separation of the images shall be parallel to that motion. The angle of rotation is measured on a graduated circle C. The angle between the objects measured = $z \sin 2\theta$, where z is a constant to be determined for each magnifying power employed,[1] and θ the angle through which the sphere has been turned from a position of coincidence of its principal axis with that of the telescope. The maximum separation is consequently at 45° from zero. The readings can be made on both sides of zero for eliminating index error. There are considerable difficulties of construction, but these have been successfully overcome by Dollond, and in the hands of Dawes (*Mem. R. A. S.*, xxxv. p. 111 *sq.*) such instruments have done valuable service. They are liable to the objection that their employment is limited to the measurement of very small angles, viz., 15″ or 14″ when the magnifying power is 100, and varying inversely as the power. Yet the beautiful images which these micrometers give permit the measurement of very difficult objects as a check on measures with the parallel-wire micrometer.

The Modern Heliometer.

The Konigsberg heliometer is represented in fig. 33. No part of the equatoreal mounting is shown in the figure, as it resembles in every respect the usual Fraunhofer mounting. An adapter h is fixed on a telescope tube, made of wood, in Fraunhofer's usual fashion. To this adapter is attached a flat circular flange h. The slides carrying the segments of the divided object-glass are mounted on a plate, which is fitted and ground to rotate smoothly on the flange h. Rotation is communicated by a pinion, turned by the handle c (concealed in the figure, which works in teeth cut on the edge of the flange h. The counterpoise e balances the head about its axis of rotation. The slides are moved by the screws a and b, the divided heads of which serve to measure the separation of the segments. These screws are turned from the eye-end by bevelled wheels and pinions, the latter connected with the handles a', b'. The reading micrometers e, f also serve to measure, independently, the separation of the segments, by scales attached to the slides; such measurements can be employed as a check on those made by the screws. The measurement of position angles is provided for by a graduated circle attached to the head. There is also a position circle, attached at m to the eye-end, provided with a slide to move the eye-piece radially from the axis of the telescope, and with a micrometer to measure the distance of an object from that axis. The ring which carries the supports of the handles a', b', c is capable of a certain amount of rotation on the tube. The weight of the handles and their supports is balanced by the counterpoise z. This ring is necessary in order to allow the rods to follow the micrometer heads when the position angle is changed. Complete rotation of the head is obviously impossible because of the interference of the declination axis with the rods, and therefore, in some angles, objects cannot be measured in two positions of the circle. The object glass has an aperture of 6½ inches, and 102 inches focal length.

Fig. 33.

Königsberg heliometer.

There are three methods in which this heliometer can be used.

First Method. One of the segments is fixed in the axis of the telescope, and the eye piece is also placed in the axis. Measures are made with the moving segment displaced alternately on opposite sides of the fixed segment.

Second Method. – One segment is fixed, and the measures are made as in the first method, excepting that the eye-piece is placed symmetrically with respect to the images under measurement. For this purpose the position angle of the eye-piece micrometer is set to that of the head, and the eye-piece is displaced from the axis of the tube (in the direction of the movable segment) by an amount equal to half the angle under measurement.

Third Method. – The eye-piece is fixed in the axis, and the segments are symmetrically displaced from the axis each by an amount equal to half the angle measured.

Of these methods Bessel generally employed the first because of its simplicity, notwithstanding that it involved a resetting of the right ascension and declination of the axis of the tube with each reversal of the segments. The chief objections to the method are that, as one star is in the axis of the telescope and the other displaced from it, the images are not both in focus of the eye-piece,[2] and the rays from the two stars do not make the same angle with the optical axis of each segment. Thus the two images under measurement are not defined with equal sharpness and symmetry. The second method is free from the objection of non-coincidence in focus of the images, but is more troublesome in practice from the necessity for frequent readjustment of the position of the eye-piece. The third method is the most symmetrical of all, both in observation and reduction; but it was not employed by Bessel, on the ground that it involved the determination of the errors of two screws instead of one. On the other hand it is not necessary to reset the telescope after each reversal of the segments.[3]

[1] Dollond provides for changing the power by sliding the lens d nearer to or further from a.

[2] The distances of the optical centres of the segments from the eye-piece are in this method as 1 : cosine of the angle under measurement. In Bessel's heliometer this would amount to a difference of $\frac{1}{1000}$th of an inch when an angle of 1° is measured. For two degrees the difference would amount to nearly $\frac{1}{10}$th of an inch. Bessel confined his measures to distances considerably less than 1°.

[3] In criticizing Bessel's choice of methods, and considering the loss of time involved in each, it must be remembered that Fraunhofer provided no means of

When Bessel ordered the Konigsberg heliometer, he was anxious to have the segments made to move in cylindrical slides, of which the radius should be equal to the focal length of the object-glass. Fraunhofer, however, did not execute this wish, on the ground that the mechanical difficulties were too great.

Wichmann states (*Konigsb. Beobacht.*, xxv. p. 4) that Bessel had indicated, by notes in his handbook, the following points which should be kept in mind in the construction of future heliometers: (1) The segments should move in cylindrical slides;[1] (2) the screw should be protected from dust;[2] (3) the zero of the position circle should not be so liable to change;[3] (4) the distance of the optical centres of the segments should not change in different position angles or otherwise;[4] (5) the points of the micrometer screws should rest on ivory plates;[5] (6) there should be an apparatus for enlarging the screen.[6]

The elder Struve, in describing the Pulkowa heliometer,[7] made by Merz in 1839 on the model of Bessel's heliometer, submits the following suggestions for its improvement:[8] (1) to give automatically to the two segments simultaneous equal and opposite movement;[9] and (2) to make the tube of brass instead of wood, to attach the heliometer head firmly to this tube, to place the eye-piece permanently in the axis of the telescope, and to fix a strong cradle on the end of the declination axis, in which the tube, with the attached head and eye-piece, could rotate on its axis.

Both suggestions are important. The first is originally the idea of Dollond (fig. 29), its advantages were overlooked by his son (description of fig. 30), and it seems to have been quite forgotten till resuggested by Struve. But the method is not available if the separation is to be measured by screws, it is found, in that case, that the direction of the final motion of turning of the screw must always be such as to produce motion of the segment against gravity, otherwise the "loss of time" is apt to be variable. Thus the simple connexion of the two screws by cog-wheels to give them automatic opposite motion is not an available method unless the separation of the segments is independently measured by scales.

Struve's second suggestion has been adopted in nearly all succeeding heliometers. It permits complete rotation of the tube and measurement of all angles in reversed positions of the circle; the handles that move the slide can be brought down to the eye-end, inside the tube, and consequently made to rotate with it; and the position circle may be placed at the end of the cradle next the eye-end where it is convenient of access. Struve also points out that by attaching a fine scale to the focussing slide of the eye piece, and knowing the coefficient of expansion of the brass tube, the means would be provided for determining the absolute change of the focal length of the object-glass at any time by the simple process of focussing on a double star. This, with a knowledge of the temperature of the screw or scale and its coefficient of expansion, would enable the change of screw value to be determined at any instant. Or, if we suppose the temperature of the instrument to be the same in all its parts, the changed scale value becomes simply a function of the reading of the focal scale.

It is probable that the Bonn heliometer was in course of construction before these suggestions of Struve were published or discussed, since its construction resembles that of the Konigsberg and Pulkowa instruments. Its dimensions are similar to those of the former instrument. Bessel, having been consulted by the celebrated statesman Sir Robert Peel, on behalf of the Radcliffe trustees, as to what instrument, added to the Radcliffe Observatory, would probably most promote the advancement of astronomy, strongly advised the selection of a heliometer. The order for the instrument was given to the Repsolds in 1840, but "various circumstances, for which the makers are not responsible, contributed to delay the completion of the instrument, which was not delivered before the winter of 1848."[10] The building to receive it was commenced in March 1849 and completed in the end of the same year. This splendid instrument has a superb object-glass of 7·1 inches aperture and 126 inches focal length. The makers availed themselves of Bessel's suggestion to make the segments move in cylindrical slides, and of Struve's to have the head attached to a brass tube; the eye-piece is set permanently in the axis, and the whole rotates in a cradle attached to the declination axis. They provided a splendid, rigidly mounted, equatorial stand, fitted with every luxury in the way of slow motion, and scales for measuring the displacement of the segments were read by powerful microscopes from the eye-end.[11] It is somewhat curious that, though Struve's second suggestion was adopted, his first was overlooked by the makers. But it is still more curious that it was not afterwards carried out, for the communication of automatic symmetrical motion to both segments only involves a simple alteration previously described. But, as it came from the hands of the makers in 1849, the Oxford heliometer was incomparably the most powerful and perfect instrument in the world for the highest order of micrometric research. It so remained, unrivalled in every respect, till 1873; it remains still, optically, the most powerful heliometer in the world, and, with a few alterations, it might almost rival the most recent instruments in practical convenience and accuracy. These alterations, all of which could be made without great difficulty, are the following:

(*a*) Beyond the automatic symmetrical motion above described the instrument should be fitted with means for adjusting the screen from the eye-end (see footnote[9] in last column).

(*b*) The arrangement of the scales should be changed. At present both scales are read separately by separate micrometers, each relative to a separate fiducial line. What the observer requires is the difference of the readings of the two scales, and this can obviously be most quickly and accurately obtained if the edges of the two scales are brought together, and both are read, relatively to each other, by the same micrometer.

(*c*) The unsatisfactory motion in position angle should be replaced by the action of a pinion (attached to the cradle) in the teeth of a wheel (attached to the tube).[12]

(*d*) The position circle should be read by telescopes or microscopes attached to the cradle, and accessible from the eye-end.

(*e*) It would add greatly to the rapidity of work and the ease of the observer if a small declination circle were attached to the cross-head, capable of being read from the eye-end.

As the transit of Venus of 1874 approached, preparations were set on foot by the German Government in good time; a commission of the most celebrated astronomers was appointed, and it was resolved that the heliometer should be the instrument chiefly relied on. The four long-neglected small heliometers made by Fraunhofer were brought into requisition. Fundamental alterations were made upon them – their wooden tubes were replaced by tubes of metal, means of measuring the focal point were provided, symmetrical motion was given to the slides; scales on each slide were provided instead of screws for measuring the separation of the segments, and both scales were read by the same micrometer microscope; a metallic thermometer was added to determine the temperature of the scales. These small instruments have since done admirable work in the hands of Schur, Hartwig, Kustner, and Elkin.

The Russian Government ordered three new heliometers (each 4 inches aperture and 5 feet focal length) from the Repsolds, and the design for their construction was superintended by Struve, Auwers

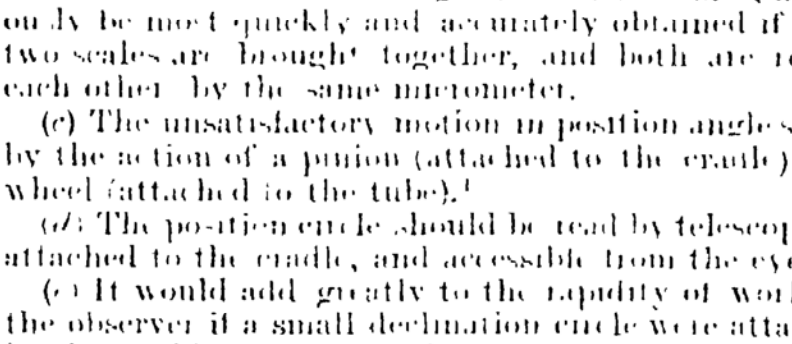

Fig. 31.

and Winnecke, the last named making the necessary experiments at Carlsruhe. Fig. 31 represents the type of instrument which

[1] This most important improvement would permit any two stars under measurement each to be viewed in the optical axis of each segment. The optical centres of the segments would also remain at the same distance from the eye-piece at all angles of separation. Thus, in measuring the largest as well as the smallest angles, the images of both stars would be equally symmetrical and equally well in focus. Modern heliometers made with cylindrical slides measure angles over two degrees, the images remaining as sharp and perfect as when the smallest angles are measured.

[2] Bessel found in course of time, that the original corrections for the errors of his screw were no longer applicable. He considered that the changes were due to wear, which would be much lessened if the screws were protected from dust.

[3] The tube, being of wood, was probably liable to warp and twist in a very uncertain way.

[4] We have been unable to find any published drawing showing how the segments are fitted in their cells.

[5] We have been unable to ascertain the reasons which led Bessel to choose *ivory* planes for the end-bearings of his screws. He actually introduced them in the Konigsberg heliometer in 1840 and they were renewed in 1848 and 1850.

[6] A screen of wire gauze, placed in front of the segment through which the fainter star is viewed, was employed by Bessel to equalize the brilliancy of the images under observation. An arrangement, afterwards described, has been fitted in modern heliometers for placing the screen in front of either segment by a handle at the eye-end.

[7] This heliometer resembles Bessel's, except that its foot is a solid block of granite instead of the ill-conceived wooden structure that supported his instrument. The object-glass is of 7·4 inches aperture and 123 inches focus.

[8] *Description de l'Observatoire central de Pulkowa*, p. 208.

[9] Steinheil applied such motion to a double-image micrometer made for Struve. This instrument suggested to Struve the above-mentioned idea of employing a similar motion for the heliometer.

[10] Manuel Johnson, M.A., Radcliffe observer, *Astronomical Observations made at the Radcliffe Observatory, Oxford, in the year* 1850, Introduction p. iii.

[11] The illumination of these scales is interesting as being the first application of electricity to the illumination of astronomical instruments. Thin platinum wire was rendered incandescent by a voltaic current. A small Swan light and condenser would probably now be found more satisfactory.

[12] This has been recently carried out by Stone, the present Radcliffe observer, on Gill's suggestion.

reading the screws or even the heads from the eye-end. Bessel's practice was to unclamp in declination, lower and read off the head, and then restore the telescope to its former declination reading, the clockwork meanwhile following the stars in right ascension. The setting of both lenses symmetrically would, under such circumstances, be very tedious.

A similar heliometer was made by the
epsold to the order of Lord Lindsay
or his Marsden expedition in 1874. It
ffered only from the three Russian in-
truments in having a mounting by the
ooke in which the declination circle
ads from the eye-end[3] This instru-
ent was afterwards most generously
nt by Lord Lindsay to Gill for his ex-
edition to Ascension in 1877

These four Repsold heliometers proved

following) for the elimination of the effect of flexure on the position angles.

There is very little left to criticize in this instrument. It embraces the results of all knowledge and experience on the subject to the present time. In one point, however, modern heliometers have a disadvantage compared with the older forms. A great advance in accuracy was, no doubt, made when the screw was abandoned as a means both of moving and measuring the displacement of the slides.[1] But it is obviously much quicker to read and record the indication of one screw head than to bisect two or four scale-divisions and enter the corresponding readings. Auwers, in his researches on the parallax of 61 Cygni,' was able, with the Konigsberg heliometer, to make forty pointings in about an hour; it is quick work to make sixteen pointings (reading two divisions on each scale at each pointing) with the modern heliometer in the same time, when attention is paid to the desirable reversal of the segments and of the position circle and the resettings in right ascension and declination. Now time during opportunities of good definition (or otherwise)[2] is too precious to be sacrificed, it can be saved even by ten-fold labour afterwards. Carrington[3] has suggested the possible use of photography to record the readings of astronomical circles, and since his day "Swan lights" and "sensitive dry plates" seems to have brought his suggestion within the range of practice. A special microscope, fitted with an aplanatic photographic objective and a well contrived carrier, might be made automatically to expose a different part of a narrow dry plate, by mere pressure or turning of a button after each bisection. Each plate might easily record the sixteen bisections which constitute a complete measure of two pairs of stars (as in a parallax determination). As it is only necessary to photograph two divisions of each scale, the photographic enlargement of these divisions need only be limited by the sensitiveness of the plates and the power of the illumination to produce a picture in a conveniently short space of time. The plates employed at night could be conveniently developed the following day and measured with a special apparatus at any convenient time and with almost any desired accuracy. Were such a system reduced to practice it would at least double, perhaps treble, an observer's possible output of work.

Gill has introduced a powerful auxiliary to the accuracy of heliometer measures in the shape of a reversing prism placed in front of the eye-piece, between the latter and the observer's eye. If measures are made by placing the image of a star in the centre of the disk of a planet, the observer may have a tendency to do so systematically in error from some acquired habit or from natural astigmatism of the eye. But by rotating the prism 90° the image is presented entirely reversed to the eye, so that in the mean of measures made in two such positions personal error is eliminated. Similarly the prism may be used for the study and elimination of personal errors depending on the angle made by a double star with the vertical. The best plan of mounting such a prism has been found to be the following. l', l^2 (fig. 37) are the eye lens and field lens respectively of a Merz positive eye-piece. In this construction the lenses are much closer together and the diaphragm for the eye is much farther from the lenses than in Ramsden's eye-piece. The prism is fitted accurately into brass slides (care has to be taken in the construction to place the prism so that an object in the centre of the field will so remain when the eye piece is rotated in its adapter). There is a collar, clamped by the screw at S, which is so adjusted that the eye-piece is in focus when pushed home, in its adapter, to this collar. The prism and eye piece are then rotated together in the adapter.

Micrometers which Involve the Employment of the Diurnal Motion

Advantage is often taken of the diurnal motion to measure the relative positions of stars. The varieties of reticles and scales that have been employed are far too numerous even for mention in detail. The following are the means and method by which most work has been done, and they are typical of all the others. In the focus of his meridian telescope Lacaille had a brass diaphragm in which was cut a hole, having parallel, sharp, straight edges of the shape shown in fig. 38. The longer diagonal of the rhomboid so formed was at right angles, and the shorter parallel, to the diurnal motion. The method of observation consisted in noting the instant of ingress and egress of each star which presented itself. The mean of the times thus noted for each star gave the time of its transit over the imaginary line ab, whence the difference between the instant of ingress and that of egress (converted into arc by the known approximate declination) gave the length of the chord traversed by the star parallel to the imaginary line cd. Hence (the camera constant of the rhomboid being known) the difference of the star's declination from the line cd became known. The observer was of course careful to note whether the star passed to north or south of cd. Thus every star that crossed the field was observed, all their right ascensions were referred to the clock time of passing cd, and all their declinations to that of cd; hence their mutual differences of right ascension and declination were known. In this way, in the short space of ten months, Lacaille observed nearly ten thousand stars at the Cape of Good Hope in the years 1751-52.

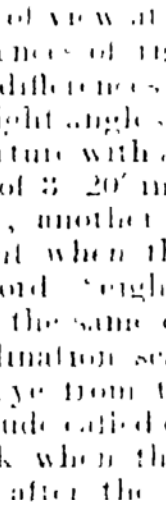

Fig. 38.

Fraunhofer's ring micrometer consists of a ring of steel, very truly turned, mounted in a hole cut in a circular disk of glass. The ring is placed in the focus of a telescope, and viewed by a positive eye piece. The observer notes the instants when the two objects enter and emerge from each side of the ring. The only data required for computing the difference of right ascension and declination of the two objects are the times above mentioned, the diameter of the ring, and the approximate declination of one of the objects. The latter is always known. The methods of determining the former and of reducing the observations are to be found in every work on practical astronomy. The ring micrometer has been largely used in observing comets.

Argelander, in making his famous survey of the northern heavens, employed a reticle of wires, the straight edge of which (true by diurnal motion) crosses the centre of the field of view at right angles to the diurnal motion of the stars. Differences of right ascension were directly observed at this edge, while differences of declination were noted by straight lines drawn at right angles to the edge at each 10′ of arc. A [illegible] 3 inches aperture with a magnifying power of 10 diameters commanded a field of 3° 20′ in declination. One observer was placed at the telescope, another at the clock. The telescope observer marked the instant when the star touched the glass edge, by calling sharply the word "eight" or "nine," &c., which also indicated the magnitude, the same observer also noted and recorded the reading of the declination scale (where the wires crossed it), without removing his eye from the telescope. The clock observer wrote down the magnitude called out by the telescope observer, and the instant by the clock when the word was given. The two records were then compared after the observations of the night were over. In this way Schönfeld and Krueger (Argelander's assistants) observed and catalogued about three hundred thousand stars. The probable error of an observation is about ±0·07 sec. in right ascension and ±0″·4 in declination.

Bond[7] employed a very similar arrangement, differing only from Argelander's in having the scale cut on a sheet of transparent mica $\frac{1}{1000}$th of an inch in thickness. Very oblique illumination was employed, and the divisions and figures were seen bright upon a dark background. The range of declination was limited to 10′, the scale was divided to 10″, the right ascensions were observed by chronographic registration, and the great refractor of the Cambridge U.S. Observatory (with an aperture of 15 inches and power of 140) was employed. The probable errors in right ascension and declination were found to be ±0·06 sec. in right ascension and ±0″·6 in declination—results of marvellous accuracy considering the amount of work accomplished in a short time and the faintness (eleven to twelve magnitudes) of the stars observed.

We were on the point of criticizing Bond's programme as somewhat too ambitious for realization without cooperation (it would take about twenty-six thousand hours of observing to carry out the northern hemisphere alone) when we received from Peters of Clinton, U. S., the first twenty maps of a series which will include the whole of the sky between declination +90° and −30°. If we consider that all the stars in these maps of the eleventh magnitude or brighter have been observed by a method similar to Bond's, that the enormous additional labour of frequent reversion has been undertaken, and all stars visible with a power of 80 on a 15 inches aperture (about fourteenth magnitude) have been filled

[1] Screws, as Auwers's discussion of Bessel's observations of Parallax in 61 Cygni," *Abhandlungen der Konigl. Akad. der Wissenschaften zu Berlin* 1868) has shown, are apt to wear and change their error. For besides, unable to apply force and friction to a delicate standard of measure.

[2] *Astron. Nachrichten*, No. 1416.

[3] For example, in determining the diurnal parallax of a planet the most favourable conditions are limited on the one hand by the uncertainties of refraction at large zenith distances, and on the other by the small parallax factors of small zenith distances. It would probably be best to secure all the observations between 50° and 60° ZD, and this would only be possible with special facilities for reading the scales.

by alignment, *and that all this results from the unaided labour of a single observer*, we shall find that our ideas of *the possible* have to be modified, when such a man undertakes a work with persistent unity of purpose for more than twenty years (1876–98).

There is another more modern mode of registering differences of declination that has been in use at the Berlin Observatory since 1879, and is described by Dr Knorre in the *Astronomische Nachrichten* for July 1881. The instrument is called the micrograph. It has a well-grooved micrometer screw, the same screw carries a tracing-point or pencil. The observer having bisected a star by the wire, keeps it so by means of an india-rubber ball connected with the micrometer screw, and moves a box made on the principle of the vacuum breaker of the aneroid barometer. The expansion of the box causes a sheet of paper in contact with two pricker-points, on the micrometer order before mentioned, the other point to move. The action of the vacuum box also automatically shifts the paper forward by a small quantity at each observation. Three successive observations are recorded in regular order. For measuring the observed differences of declination it is the easiest way to measure with a glass scale divided for the purpose corresponding to the distance of each record of the moving pricker from the fixed pricker. It is found, with the declinometer at the Berlin equatorial, that the observed declinations have a very probable error of 1″·0. It is obvious that by using a barograph in connection with this instrument both right ascensions and declinations could be recorded with great accuracy and rapidity.

Heliometric Micrometers.

Clausen (*Astr. Nach.*, No. 111) proposed a form of micrometer consisting of a divided plate of parallel glass placed within the cone of rays from the object-glass at right angles to the telescope axis. One half of this plane remains fixed, the other half is movable. When the inclination of the movable half with respect to the axis of the telescope is changed by rotation about an axis at right angles to the plane of division, two images are produced. The amount of separation is very small, and depends on the thickness of the glass, the index of refraction, and the focal length of the telescope. Secchi (*Comptes Rendus*, xli., 1855, p. 906) gives an account of some experiments with a similar micrometer, and Porro (*Comptes Rendus*, xlv. p. 1058) claims the original invention and construction of such a micrometer in 1845. Clausen, however, has undoubted priority. Helmholtz in his "Ophthalmometer" has employed Clausen's principle, but arranges the plates so that both move symmetrically in opposite directions with respect to the telescope axis. Should Clausen's micrometer be employed as an astronomical instrument it would be well to adopt the improvement of Helmholtz.

Burton and Grubb (*Monthly Notices*, vol. xli. p. 596), after calling attention to Lamont's paper *Jahrbuch d. k. S. b. Munchen*, p. 187, and Lattrow's paper *Proc. of Vienna Acad. of Sciences*, vol. xx. p. 265, on a like subject, proceed to describe a most ingenious form of "Ghost Micrometer," in which the *image* of a fine line or lines ruled on (or rather cut through) a silver film deposited on glass is formed at the common focus of an object-glass and eye-piece of a telescope. A faint light being thrown on the outside of the silvered plate, there appear bright lines in the field of view. We have not had an opportunity of testing this, nor Grubb's more recent models; but should it be found possible to produce such images satisfactorily without diffraction and with an apparatus convenient in general form, such micrometers will probably supersede the ordinary micrometer. Their absolute freedom from diffraction, the perfect control of the illumination and thickness of the lines, and the facility with which it will be possible to construct scales for any required purpose, will be important features of the new method.

For the use of micrometers in connexion with the microscope, see p. 277 of the present volume. (D. GI.)

MICRONESIA. The term "Micronesia" embraces that region of the Pacific north of the great Melanesian islands, where, either perhaps from a greater or more rapid subsidence, or from the decreasing activity northwards of the coral builders, the islands become, generally speaking, smaller and lower, and finally cease. Accordingly, excepting the Marianas or Ladrone, which are of volcanic origin, and a few isolated instances of elevation in the Carolines, the Micronesian islands, though many of the groups cover a vast area, are almost without exception very small low coral (atoll) formations. Besides the LADRONE and CAROLINE ISLANDS (*q.v.*) Micronesia includes the Marshall and Gilbert groups, and some geographers include the Anson group, a number of small widely-scattered islets to the west of Hawaii, the M group farther west, and the Bonin Islands north Ladrones.[1]

North-easterly winds prevail during the winter over the Marshalls, Ladrones, and Carolines, e the extreme west, while between May and Septem influence of the monsoon causes unsettled weath the west, with heavy gales. In the Gilberts the s trade-wind brings fine weather at this season.

The ethnological features of Micronesia are mu definite than the geographical, for its populatio one great branch of the fair Polynesian race, distin from the other by well-marked differences in app language, and institutions. Its ethnological relat not thoroughly understood. The proximity of Ja the Philippine on the west and of the Papuan an Polynesian islands on the south and south-east s what in fact we find, a combination of elements in degrees of fusion. In some places the oblique M eye is noticed, and (along with certain Indo customs) there is often a scantiness of beard and "Malay" look, which increases westwards, and s imply relations with the archipelago subsequent departure thence of the pure Polynesians. In the the traces of Polynesian (Samoan) influences are and are confirmed by tradition. Among the Carol the Marshalls darker and more savage communi found, suggesting a Melanesian element, which is traceable in the Ebon (Marshall) and other langua

Each of the four groups, from long isolation, ha oped peculiarities of its own. The most advanc the "Chamorros" of the Ladrones, owing to the natural resources of the islands, and perhaps more contact with influences from the west; but as a people they no longer exist, having been nearly ex ated by the Spaniards in the 17th century. advancement come the Carolines. The general t well-proportioned rather slightly built figure, wit and regular features; head high and well-prope but forehead rather retreating, and narrow at the t cheek bones and chin slightly prominent; colour so darker than the Polynesians, the Marshalls being and more vigorous than the Carolines, while the type is still darker and coarser. The upper class surpasses the common people in physique and intel

There is a peculiar division of society into clans, the membership of which constitutes the clo Persons of the same sept must not intermarry, an two islands or communities meet in war the men one sept, however widely separated by distance or time, will not injure or fight with each other. community is usually composed (but there are loca ences) of —(1) an upper class of chiefs, from among the head (*tamol* or *iros*) is chosen; (2) a lower noble class; and (3) common people, mostly rights of property. These last are only allowed o Assemblies of the chiefs everywhere limit the authority. In the Marshalls the sovereign has control over many of the atolls, and in the Gilb above distinctions have nearly disappeared; the h has lapsed, and, especially in the southern islands, t of largest substance is the most powerful, and so establishes a local supremacy. Here and there are as in Tonga, of a spiritual sovereign, the desc probably of a conquered dynasty. Succession is the female side, which assures to women a certain

[1] These islands, which contain a mixed immigrant popula claimed, and have been recently surveyed, by Japan. But annexed to England by Captain Beechey in 1827. (See Von *Denkwürdigkeiten einer Reise nach . . . . Mikronesien*, &c.

eads besides to some curious results (see paper by y in *Das Ausland*, 1880, No. 27). The upper class ie keepers of traditions, boat-builders, leaders of tions; tattooing is generally done by them, the t increasing with a man's rank; the custom here as definite religious associations. Both sexes are ed. The people are singularly amiable and well ed, but will repay ill usage with treachery. The n (although chastity is not expected before marriage) newhat more moral than the Polynesians, and are d with respect, as are the aged. The natives are and hospitable to strangers (except on the poorer and islands), bright and intelligent, active traders, expert ators and fishermen. They have a hand-loom from beautiful fabrics of banana, hibiscus, and other fibres roduced. The Marshall Islanders are the boldest ost skilful navigators in the Pacific. Their voyages any months' duration, in great canoes sailing with ger to windward, well-provisioned, and depending on kies for fresh water, help to show how the Pacific olonized. They have a sort of chart, *medo*, of small tied together, representing the positions of islands e directions of the winds and currents. A two-edged n, of which the blade is of sharks' teeth, and a sive armour of braided sennit, are also peculiar to the s; a large adze, made of the *Tridacna gigas*, was rly used in the Carolines, probably by the old r race.

languages of Micronesia, though grammatically alike, differ in their vocabularies. They have the chief characteristics Polynesian, with Malay affinities, and peculiarities such as the suffixes and inseparable pronouns and, as in Tagal, of the infix ote changes in the verb; in the west groups there is a tend- closed syllables and double consonants, and a use of the pala- *j*, *sh*, the dental *th*, and *s* (the last perhaps only in foreign , which is alien to the Polynesian. These letters are g in the Gilbert language, which differs considerably from others, and has much greater affinities with the Polynesian. religious myths are generally identifiable with the Polynesian, belief in the gods proper is overshadowed by a general tion of ancestors, who are supposed from time to time to certain blocks of stone, set up near the family dwelling, and nded by circles of smaller ones. These stones are anointed il, and worshipped with prayer and offerings, and are also used rposes of divination, in which, and in various omens, there is ral belief. In the Marshalls, in place of these stones, certain trees are similarly enclosed. The spirits also sometimes t certain birds or fishes, which are then *tabu*, as food, to the ; but they will help to catch them for others. All this recalls the *karwars* or ancestral images of New Guinea. es are very rare, though these blocks of coral are sometimes nded by a roofless enclosure opening to the west. The bodies dead, and sometimes even of the sick, are despatched to sea ards, with certain rites; those of the chiefs, however, are , for the order has something essentially divine about it, odies therefore are sacred, and their spirits naturally assume sition above described. Such a belief greatly strengthens the authority, for the spirits of his ancestors are necessarily more ful than any other spirits. Thus too it comes that the chiefs, l belonging to them, are tabu as regards the common people. are various other subjects and occasions of tabu, but the tion has not the oppressive and all-pervading character it has in Polynesia. Its action is often economical or able, *e.g.*, the ripening cocoa-nuts are tabu as long as the bread- asts, thus securing the former for future use; or it is put on death, and the nuts thus saved are given to the family—ness to them, and a mark of respect for the dead.

flora of the Gilbert and Marshall groups is of the usual c character, with close Indo-Malay affinities. It is much than that of the Carolines,[1] with its Moluccan and Philip- lements, and this again is surpassed by that of the Ladrones. e Gilberts the scattered woods of cocoa-palm and *Pandanus* ittle undergrowth, while the south Marshalls, being within the constant precipitation, have a dense growth of (mostly) low and shrubs, with here and there a tropical luxuriance and y unusual on atolls. The *Pandanus* grows wild profusely, and xceptional importance, being the chief staple of food, so that the cocoa-nut, which, however, flourishes chiefly in the G used mainly to produce oil for exportation. The bread-fr chiefly in the south Marshalls. The taro (*Arum co* and others) is cultivated laboriously, deep trenches bei the solid rock for its irrigation, but this and other plants o tion, and indeed the vegetation generally, fall off in nu quality northwards. Various vegetables are grown on ported for the purpose. Marine plants are rare. Wilkes Makin Island, Gilbert group, a "fruit resembling the goo called "teiparu," from which a preserve is made. This s like the tipari or Cape gooseberry of India (*Physalis pe* And their *karaka*, a drink made from the sap of the flowe the cocoa-palm (unfermented before the arrival of European the attack of southern Asia.

The fauna, like the flora, becomes poorer eastwards, bi much more numerous on the high islands than on the ato the few are chiefly aquatic. On Bonabe (Puynipet) out o nine species eleven are sea birds, and of the remaining eight are peculiar to the island. From the Pelews fifty-six s recorded (twelve peculiar), and from the neighbouring M group (Ulithi) twenty (six peculiar). Yet curiously no recorded common to these two groups and peculiar to th common fowl is found everywhere, wild or tame, and in so is kept for its feathers only. The rat and a *Pteropus* are indigenous land mammals. The Indian crocodile is fou east as the Pelews. There are five or six lizards, in *Gecko* and *Ablepharus*. Insects are numerous, but of f Scorpions and centipedes are common, but are said to be

The houses in the Gilberts and Marshalls (much less than in the Carolines) consist merely of a thatched roof r posts or on blocks of coral about 3 feet high, with a flo level, which is reached from an opening in the centre. the principal people sleep, and it serves as a storeh accessible to rats, which infest all the island.

The Marshall archipelago consists of two nearly parall of atolls, from 100 to 300 miles apart, the west known as east as Ratak. They lie between 4° 30′ and 12° N., and 165° 15′ and 172° 15′ E., and run about N.N.W. a They were discovered in 1529 by Saavedra, who, observing tattooing of the inhabitants (the first allusion to the p the Pacific), called them Los Pintados. Among modern Wallis first visited them in 1767; Captains Marshall bert reached them in 1788, and Kotzebue (1816) explo more thoroughly. Each group contains fifteen or sixte which range from 2 to 50 miles in circumference. An a feature is reported on some of them, viz., that the gr portion of land, or at all events of oil, is not found as us windward side of the lagoon, for the prevailing north sweeps, it is said, the materials of which the soil of such composed across to the lee side. Jaluit Island is the e emporium of the whole region. There is a curious tra Ebon Island of the Darwinian fact that the atoll once f barrier reef of an island now sunk beneath the lagoon. T tion of Ratak is about 6000, of Ralik 4000; there is little u between the two groups.

The Gilbert archipelago, discovered by Byron in geographically a south continuation of the Marshalls, th separating them being 50 leagues wide. It lies betwe S. and 3° 20′ N., and between 172° 30′ and 177° 15′ E., tains sixteen atolls, not including two hilly islands, Ba Nawodo, which lie 5 to 6° to the west. Several have good a inside the lagoon, with entrances on the lee side. On so or west reef is wanting, owing to the abrading force of storms. During these large trees are washed ashore, t containing pieces of fine basalt, of which implements There is a far larger proportion of land to submerged lagoon than in the Marshalls, the land sometimes risi above the sea, whereas in the Marshalls the average le reef rock is less than a foot above the surface; but, th supply of fresh water is exceptionally great, in fact enou luxury of a bath, the soil (especially in the south) is very productive. Yet the population, about 50,000, is exc dense. The usual scattered houses are replaced by com of roofs which, shaded by cocoa-palm, and each with its below, line the shore. Their numbers are unchecked eit constant practice of abortion or by fighting, to which much addicted, their weapons being more formidable t of their neighbours. This exceptional vigour may be decidedly hybrid character of the race. Hawaiian mi under American superintendence, have laboured here su

[1] About 180 species have been observed on Kusaie, one-fourth of plants being ferns.

MICROPHONE. See TELEPHONE.

MICROSCOPE

E microscope is an optical instrument for the examination of minute objects or parts of objects, enlarge the visual pictures formed upon the retina observer by the rays proceeding from them.

roscopes are distinguished as *simple* or *compound*. former, the rays which enter the eye of the observer from an object brought near to it after refraction h either a single lens or a combination of lenses as a single lens, its action as a "magnifier" depend its enabling the eye to form a distinct image of the at a much shorter distance than would otherwise be . The latter consists of at least two lenses, so placed ly to the object, to the eye, and to one another that ged image of the object, formed by the lens placed to it (the "object-glass"), is looked at through the nt the eye (the "eye-glass"), which acts as a roscope in "magnifying" it, so that the com roscope may be described as a simple microscope look at an enlarged image of the object, instead he object itself.

ory of the Simple Microscope.—Any solid or liquid rent medium of lenticular form having either one and one flat surface or two convex surfaces whose nt coincident, may serve as a "magnifier," what is ial being that it shall have the power of so refracting rays which pass through it as to cause widely ing rays to become either parallel or but slightly ent. Thus if a minute object be placed on a slip of and a single drop of water be carefully placed upon drop will act as a magnifier in virtue of the con of its upper surface, so that when the eye is at sufficiently near it (the glass being of course held ntally, so as not to distort the spherical curvature of op) the object will be seen much enlarged. And if ll hole be made in a thin plate of metal, and a drop of water be inserted in it, this drop, having onvex surfaces, will serve as a still more powerful fier. There is reason to believe that the magnifying wer of transparent media with convex surfaces was arly known. A convex lens of rock crystal was by Layard among the ruins of the palace of Nimrud. is pretty certain that, after the invention of glass, spheres blown of that material and filled with were commonly used as magnifiers (comp. vol. xiv.). The perfection of gem-cutting shown in ancient especially in those of very minute size, could not been attained without the use of such aids to the power, and there can be little doubt that the rs who could execute these wonderful works could hape and polish the magnifiers best suited for their r other." i. e. Though it is impossible to say when x lenses of glass were first made by grinding, it is certain that they were first generally used to assist ry vision as "spectacles," the use of which can be back nearly six centuries; and not only were cle-makers the first to produce glass magnifiers (or e microscopes), but by them also the telescope and the ound microscope were first invented. There seems ason to believe, however, that lenses of very high fying power (or short focus) were produced until and for them had been created by the introduction e compound microscope, in which such lenses are ed as "object-glasses"; and the difficulty of working of high curvature with the requisite accuracy led in st instance to the employment of globules made by the ends of threads of spun glass. It was in this way that Robert Hooke shaped the minutest of the with which he made many of the numerous disc recorded in his *Micrographia*; and the same metho employed by the Italian microscopist Father Di Tor seems to have been Leeuwenhoek that first succee grinding and polishing lenses of such short foc perfect figure as to render the simple microscope a instrument for most purposes than any compound scope then constructed,—its inferiority in magnifying being more than counterbalanced by the superior cl of the retinal picture. And, in despair of any such fication in the compound form as should remove the defects which seemed inherent in its plan of constr scientific opticians and microscopic observers alik their chief attention for a considerable period improvement of the simple microscope. In order t nature of these improvements may be understoo principle of its action must be first explained.

The normal human eye has a considerable power adjustment, by which its focal length is so varied forms equally distinct pictures of objects brought ordinary reading distance (say 10 inches) and of whose distance is many times that length,—the size visual picture of any object diminishing, however the increase in the distance to which it is removed, amount of detail distinguishable in it following th proportion. Thus a man who looks across the stre placard posted on the opposite wall may very distinc its general form and the arrangement of its heading, a be able to read what is set forth in its largest type, unable to separate the lines, still more to read the of what is set forth below. But by crossing the so as to bring his eye nearer the picture he finds able to read the smaller type as easily as he befo the larger,—the visual picture on his retina havin magnified, say 10 times in linear dimension, reduction of the distance of his eye from 40 fee Similarly, if he holds a page of excessively minute arm's length (say 10 inches) from his eye, he may be to read it, not because his eye does not form a retinal picture of the page at that distance, but the details of that picture are too minute for distinguish them. But if he brings the page fr inches to 10 inches distance, he may be able to without difficulty,—the retinal picture being enlarg times linear (or sixteen times superficial) by this a mation. Now the rays that enter the eye from eac of a remote object diverge so little as to be vi parallel; but the divergence increases with the appr tion of the object to the eye, and at 10 inches th of their divergence is as wide as permits the ordin to bring them to a focus on the retina. When the is approximated more closely, an automatic contrac the pupil takes place, so that the most diverging each pencil are cut off, and a distinct picture formed (though not without a feeling of strain) wh object is (say) from 5 to 8 inches distant,—givi greater minuteness of visual detail in conformity w increase of size. A further magnifying power obtained without the interposition of any lens, by at an object, at 2 or 3 inches distance, through a in a card; for by thus cutting off the more di rays of each pencil, so as to admit only those wh be made to converge to a focus on the retina distance, a distinct and detailed picture may be ob though at the expense of a great loss of light. Mo

...encils which issue from its several points, so that
...nter the eye at the moderate divergence which they
... have if the object were at the ordinary nearest limit
...inct vision. And, since the shorter the focus of the
...e more closely may the object be approximated to
...e, the retinal picture is enlarged, causing the object
...pear magnified in the same proportion. Not only,
...er, are the component rays of each pencil brought
...divergence into convergence, but the course of the
... themselves is changed, so that they enter the eye
... an angle corresponding to that under which they
... have arrived from a larger object situated at a
...r distance; and thus, as the picture formed upon the
... by the small object *ab*, fig. 1, corresponds in all

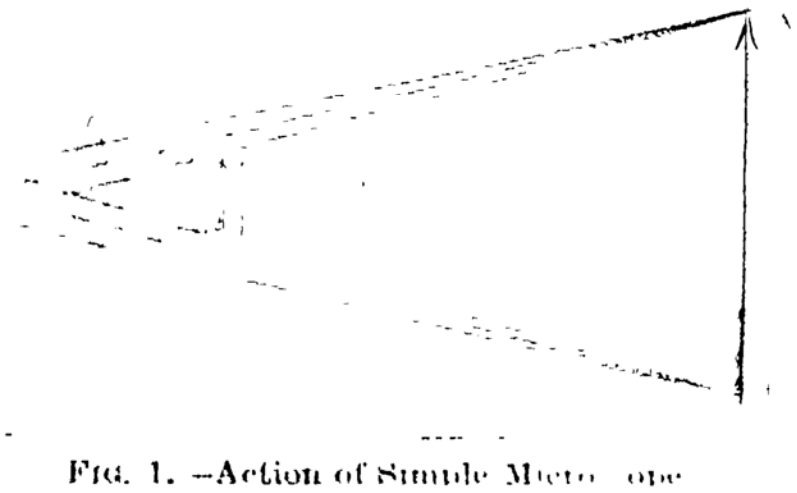

FIG. 1.—Action of Simple Microscope.

...ts with that which would have been made by the
...object AB of several times its linear dimension
...d at the nearest ordinary limit of distinct vision, the
... is seen (by the formation of a "virtual image") on
...nified scale.

...is obvious that the "magnifying power" of any
...x lens so used is measured by the ratio between the
...sions of the retinal picture formed with its assistance
...ose of the picture formed by the unaided eye. Thus,
...he use of a convex lens having 1 inch focal length
...n form a distinct retinal image of an object at only
...ch distance, this image will have ten times the
... dimensions of that formed by the same object at a
...ce of 10 inches, but will be only eight times as large
...e picture formed when the object can be seen by
...ry vision at 8 inches distance, and only four times
...ge as the picture of the same object formed by a
...c eye at a distance of 4 inches. It is usual to
...te the magnifying power of single lenses (or of com-
...ons that are used as such) by the number of times that
...ocal length is contained in 10 inches,—that of 1 inch
... being thus taken as ten times, that of $\frac{1}{10}$ inch as
...ndred times, and so on. But the rule is obviously
...ary, as the actual magnifying power varies in each
...dual with the nearest limit of distinct vision. Thus
...e myopic who can see an object clearly at 4 inches
...ce, the magnifying powers of a 1 inch and $\frac{1}{10}$ inch
...ill be only 4 and 40 respectively. The amplifying
... of every single convex lens, however, is impaired (1)

When combinations of this kind a...

eted, spherical aberration is almost wholly got rid chromatic dispersion is so slight that the angle of e may be considerably enlarged without much of distinctness. Such "doublets" and "triplets," been brought into use in England while the com- microscope still retained its original imperfections, very serviceable to such as were at that time ting minute biological investigations: for example, mirable researches of Dr Sharpey on ciliary action nals (1830-35) and Mr Henry Slack's beautiful ons of the elementary tissues of plants, as well as ellent observations on vegetable cyclosis (1831), ade by their means. No one, however, would now lla.ton "doublet" or "triplets" of high power in a compound achromatic microscope; and for the microscopes of low power that are useful either for g or for picking out minute specimens (such as other constructions are preferable, as giving a ield and more light. As a hand magnifier the ngton lens, which is a sphere of glass with a oove ground out of its equatorial portion, has lvantages.[1] By making this groove sufficiently oth spherical and chromatic aberrations can be almost insensible, and, as the rays falling on any he spherical surface can only pass to the eye either or near the centre, the action of every part of that the same, so that the image of the object will be ht, the eye (when properly focussed) whether its parts r to the axis of the sphere or more remote from it, is be itself turned to one side or the other. Again, athematically shown by Sir John Herschel in 1821 the combination of a meniscus with a double con- the four surfaces of these lenses having certain onate curvatures spherical aberration could be extinguished for rays parallel to the axis, the tion being thus an "aplanatic" doublet, while combination, which he termed a "periscope," gives a remarkable range of oblique vision with vers, and almost entirely extinguishes chromatic on, although at the expense of residual spherical on. These combinations have been mounted both -magnifiers and as single microscopes, for both rposes they are much superior to single lenses of magnifying power. But such combinations have atly improved by the introduction of concave of s, so as to render them achromatic as well as e, and nothing, according to the writer's experi- n now be used with greater advantage for all the s answered either by the simple microscope or d magnifier than Browning's "platyscopic" lenses "achromatic doublets" of Steinheil of Munich the combinations gives a large flat field, with t light, admirable definition, and freedom from ion.

pared above "doublets" of very short focus were used in order to be magnifying power, it was requisite to mount n that would enable the focal adjustment to be d would permit the use of a special illuminating apparatus at one side. But now that comparatively low powers employed the coarse rack and pinion movement is quite for their focal adjustment and nothing more is required

difficult to understand how the name of Coddington came to ned to the grooved lens, seeing that he neither was nor to be the inventor of it. Dr Wollaston's first "doublet" of a pair of plano-convex lenses with their plane surfaces to each other, and a stop diaphragm with central aperture placed them. Sir D. Brewster has shown that this construction is most ous when the two lenses are hemispheres, and the central between their two plane surfaces is filled up by a transparent ving the same refractive index as glass. And from this the is obvious to the grooved sphere, which had been made for rewster long before the high commendation it received from ngton brought it into general repute.

for the illumination of the object than a concave mirror beneath the stage when it is transparent, and a condensing lens above when it is opaque. The various patterns of simple microscope now made by different makers vary in their construction, chiefly in regard to portability, the size of their stages, and the mode in which "rests" or supports to the hands are provided. These, in Continental instruments, are very commonly attached to the stage; but, unless the stage itself and the pillar to which it is fixed are extremely massive, the resting of the hands on the supports is apt to depress the stage in a degree that affects the focal adjustment; and where portability is not an object it seems better that the hand-supports should be independent of the stage. For a laboratory microscope, the pattern represented in fig. 2 has been found very convenient,—the framework being of mahogany or other hard wood, the stage

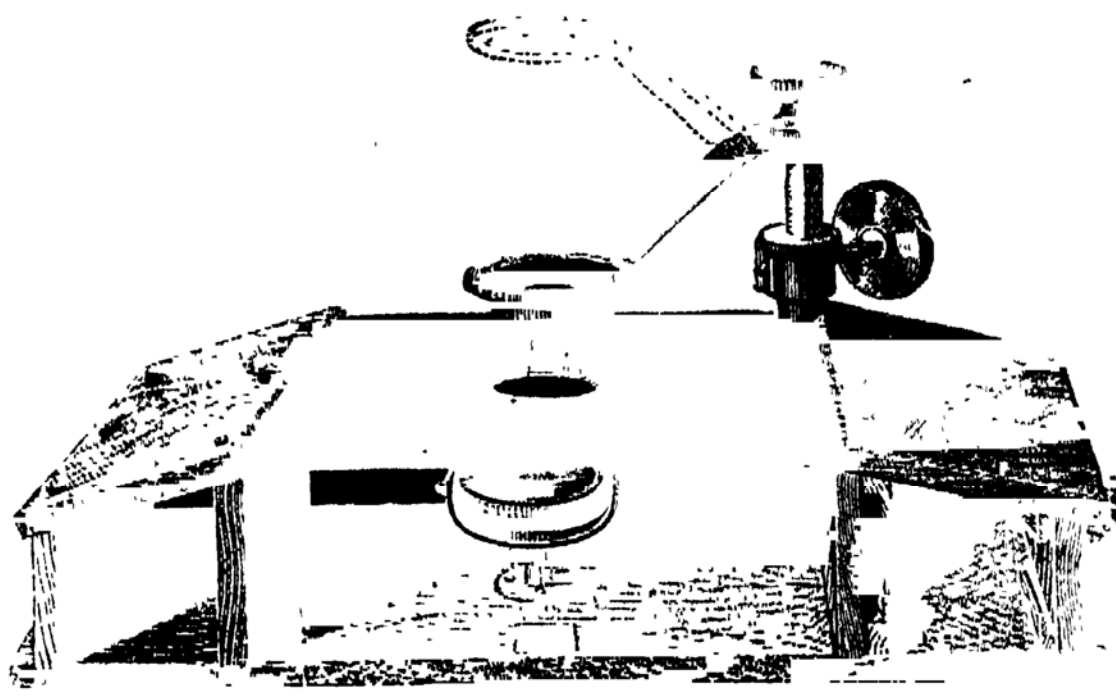

Fig. 2.—Laboratory Dissecting Microscope.

being large enough to admit a dissection or carry a water-trough of considerable size, and the bent arm that carries the "powers" being made capable of reversion, so as to permit the use of lenses of very long as well as of very short focus. As it is desirable that the stage should not be acted on chemically by sea-water, acids, or other reagents, it may be made either of a square of plate-glass or of a plate of ebonite with an aperture in the middle; and either of these may be made to slide in grooves in the side supports, so that one may be substituted for the other. The arm may be easily made (if desired) to carry the body of a compound microscope, so as to apply it to the examination of objects dissected or otherwise prepared under the simple microscope, without transferring them to another instrument. A portable form of simple microscope is shown in fig. 30.

Compound Microscope.—The placing of two convex lenses in such relative positions that one should magnify an enlarged image of a small near object formed by the other naturally soon followed the invention of the telescope, and seems to have first occurred to Hans Zansz or his son Zacharias Zansz, spectacle makers at Middelburg in Holland, about 1590. One of their compound microscopes, which they presented to Prince Maurice, was in the year 1617 in the possession of Cornelius Drebell of Alkmaar, who then resided in London as mathematician to king James I. In order to make clear the successive stages by which the rude and imperfect microscope of that period has, after remaining for two centuries unimproved in any essential particular, been developed within the last half-century into one of the most important instruments of scientific research that the combination of theoretical acumen and manipulative skill has ever produced, it is necessary to explain the principle of its construction, and to show wherein lay the imperfection of its earlier form.

In its simplest construction, as already stated, the compound microscope consists of only two lenses,—the "object-glass" OD, fig. 3, which receives the light-rays direct from the object AB placed near it, and forms an enlarged but reversed image A′B′ at a greater distance on the other side, and the "eye glass" LM, which receives the rays that diverge from the several points of this image as if they proceeded from the points of an actual object occupying the position and enlarged to the dimensions A′B′, and brings these to the eye at E, so altering their course as to

simple microscope in magnifying that image to the
r. It was early found useful, however, to interpose
lens FF, fig. 4 (the "field-glass"), between the
glass and the image formed by it, for the purpose
ng such a slight convergence to the pencil of rays as
duce the dimensions of the image, and thus allow
r part of it to come within the range of the eye

Diagram of Simplest
of Compound Micro-

FIG. 4. Diagram of Complete
Compound Microscope.

so that more of the object can be seen at once.
t was soon perceived that the eye-glass and the
ass might be advantageously combined into an
piece," in which a perforated diaphragm might be
d at the focal plane of the image (*i.e.*, in the focus of
e-glass), so as, by cutting off the peripheral portion
field of view, to limit it to what can be seen with
le distinctness.

s obvious that the magnifying power of such an
ment would depend (1) on the proportion between
ze of the image formed at BB and that of the
object, and (2) upon the magnifying power of the
ss. And further the proportion which the size of
age bears to that of the object depends upon two
,—(1) the focal length of the object glass, and
e distance between the object-glass and the plan
ccupied by the image it forms. If we dimmish
cal length of the object-glass, the object must be
t nearer to it, so that, while the distance of the
on the other side remains unchanged, that distance
to bear a larger proportion to the distance of the
and the size of the image is augmented in a cor-
ding ratio. On the other hand, the object glass
ning unchanged, the distance at which it forms the
of the object can be increased by a lengthening of the
f the microscope; and, as this involves a shortening
of the distance between the object-glass and the obje
proportion which the former bears to the latter is augm
and the image is correspondingly enlarged. Th
increase in the magnifying power of the compound
scope may be gained in three modes, which may b
either separately or in double or triple combination,
(1) shortening the focus of the object-glass, (2) lengt
the tube of the microscope, and (3) increasing the ma
ng power of the eye glass by shortening its focus.
t may be remarked, also lengthens the distance
mage from the object glass, by bringing the foca
BB nearer the eye glass. The second of these m
was not unfrequently used in the older microscopes,
were sometimes made to draw out like telescopes, s
increase the amplifying power of their object glasses.
whilst very inconvenient to the observer, such a len
ing of the one distance involved such a shortening
other as greatly impaired the distinctness of the im
increasing the aberrations of the object glass, so th
method came to be generally abandoned for one of the
two

When lenses of from 1 to 4 inches focus were u
object glasses, and their apertures were restricted by
to the central part of each, tolerably distinct image
given of the larger structural arrangements of such obj
sections of wood or the more transparent wings of ins
which images would bear a further moderate enlarg
by the eye glass without any serious deterioration ei
want of definition or the introduction of colour f
But when lenses of less than 1 inch focus were em
in order to obtain a higher magnifying power, the
obliquity of the rays so greatly increased their aber
that defective definition and the introduction o
colours went far to nullify any advantage obtainabl
the higher amplification, while the limitation
aperture required to keep these aberrations withi
moderate limits occasioned such a loss of light a
seriously to detract from the value of the picture.
other hand, the use of deeper eye pieces to enlarg
images formed by the object glasses not only brou
more strongly all the defects of those images, but intr
a new set of errors of their own, so that very litt
gained by that mode of amplification. Hence many
best of the older microscopists (notably LEEUWE
q.v.) made some of their most valuable discoveries
use of the simple microscope; and the amount of ex
work thus done surprises every one who studies the
of microscopic inquiry. This was still more the
already stated, when the use of single lenses of ver
focus was superseded by the introduction of the Wo
doublet. And the substitution of these doublets
single lenses of object glasses, while the single lens
eye glass was replaced by a Herschel's aplanatic d
and the field glass was a convex lens whose two curv
the proportion of 1:6 (the form of least spherical
tion), constituted the greatest improvement of wh
instrument seemed capable in pre-achromatic times.

It has been only within the last sixty years (18
that the microscope has undergone the important i
ment which had been worked out by Dollond
refracting telescope more than sixty years previ
namely, the correction of the chromatic aberration
objectives by the combination of concave lenses

[1] This combination was made in the first microscope of w
writer became possessed, about the year 1830, and he well
the great superiority to any compound microscope of the old
tion which was proved by its power of separating the lin
Menelaus scale, and of bringing into view the detail of the str
animalcules, with a clearness that only an achromatized ob
could surpass.

with convex lenses of crown, while their spherical
tion is corrected by the combination (as in Herschel's
tic doublet) of convex and concave surfaces of
nt curvatures. The minute size and high curvature
lenses required as microscopic objectives were long
ered as altogether precluding the possibility of success
production of such combinations, more especially
condition, they would have to meet differ altogether
those under which telescopic object-glasses are
yed. For the rays from distant objects fall upon the
with virtual parallelism and the higher the power
ed the longer is the focus given to them, and the
r is the deflexion of the rays. In the microscope, on
ner hand, the object is so closely approximated to the
ve that the rays which proceed to it from the latter
always a very considerable divergence; and the
on to which they are subjected increases with that
ion of the focal length of the objective which is
cessary condition of the increase of its magnifying
And thus, although the telescopic "triplet"
l out by Dollond (consisting of a double concave of
ass, interposed between two double convex lenses of
can be so constructed as to be not only completely
ic (or free from spherical aberration) but almost
tely achromatic (or free from chromatic aberration),
nstruction is only suitable for microscopic objectives
foci and small angular aperture, the rays falling
ich have but a very moderate divergence. At
, as will presently appear, some of the early attempts
achromatization of the microscope were made in
rection, it was soon abandoned for other plans of
ction, which were found to be alike theoretica
retically superior.

eems to have been by Professor Amici, in
, about 1812, that the first attempts were made at
romatization of microscopic objectives, but, these
ts not proving successful, he turned his attention to
oduction of a reflecting micro-scope, which was a
improvement upon the non achromatized compound
opes then in use. In the year 1820, however, the
was taken up by Selligues and Chevalier of Paris,
dopted the plan of superposing three or four com
e, each consisting of a double convex of crown
d to a plano concave of flint. The back combina
at nearest to the eye) was of somewhat lower po ver
ose placed in front of it, but these last w of
e focus, and no attempt was made by these opticians
the construction of the several pairs thus united
to make them correct each other's aberrations
although a considerable magnifying power could
obtained, with an almost complete extinction of
the aberration, the aperture of these objectives
not be greatly widened without the impairment of
definition of the image by a "coma" proceeding
uncorrected spherical aberration.

Ignorance, it would appear, of what was being done
Paris opticians, and at the instigation of Dr Goring
ntific amateur, Mr Tulley, well known in London
able constructor of telescopic objectives, began,
he year 1824, to work object glasses for the micro
on the telescope plan. After many trials[1] he
ed, in 1825, in producing a triplet of $\frac{3}{10}$ inch focus,
ng a pencil of 18°, which was so well corrected as
form very satisfactorily with an eye-piece giving a
ying power of 120 diameters. He afterwards made
r triplet of shorter focus, which, when placed in
front of the previous one, increased the angle of th
mitted pencil to 38°, and bore an eye-piece gi
magnifying power of 300 diameters. These tripl
said by Mr Ross to have never been exceeded by any
combinations for accurate correction throughout the

Having come into possession, at the end of 1
an objective of Chevalier's construction, Mr J. J.
carefully examined its properties, and compared the
those of Tulley's triplets; and this comparison hav
him to institute further experiments he obtained
which were at first so conflicting that they mus
proved utterly bewildering to a less acute mind,[2] bu
finally led him to the enunciation of the principle on
all the best microscopic objectives are now const
For he discovered that the performance of such
posite objectives greatly depends upon the relative p
of their component combinations,- the effect of t
plano concave upon the spherical aberration produ
the double convex of crown varying remarkably ac
to the distance of the luminous point from the from
objective. If the radiant is at a considerable dista
rays proceeding from it have their spherical error
corrected; but, as the source of light is brought ne
the glass, the flint lens produces greater propor
effect, and the under-correction diminishes, until at
a point is reached where it disappears entirely, th
being all brought to one point at the conjugate f
the lens. This then, is one aplanatic focus. If, h
the luminous point is brought still nearer to the gl
influence of the flint continues for a time to increa
he opposite condition of over correction shows itself
on still further approximation of the radiant, th
comes to operate with less effect, the excess of co
diminishes and at a point still nearer to the glass va
and a second aplanatic focus appears. From thi
onwards under correction takes the place of over-cor
and increases till the object touches the surface
glas As every such doublet, therefore, has two ap
foci for all points between which it is over-corrected
for all points beyond it is under-corrected, the opt
enabled to combine two or more doublets with
security against spherical error. This will be
avoided if the rays be received by the front glass f
shorter aplanatic focus, and transmitted through th
glass in the direction of its longer aplanatic pene
the approximation of the two doublets over-correcti
be reduced, while their separation will produce an
rection; and thus, by merely varying the distance b
two such combinations, the correction of the sp
error may be either increased or diminished accordi
definite rule. Slight defects in one glass may t
remedied by simply altering its position in relation
other, an alteration which may be made with ver
disturbance of the colour-correction. This imp
principle was developed and illustrated by Mr List
memoir read to the Royal Society on January 21,
On some Properties in Achromatic Object-glasses, app
to the Improvement of the Microscope; and it was by
ing on the lines there laid down that the three
opticians Ross,[3] Powell, and James Smith soo

[1] due to Mr Joseph J. Lister to mention that Tulley's final
with this low power seems to have been attained by working
gestion given him by that gentleman. See *Monthly Micro-*
Journal, vol. III. (1870), p. 134.

[2] Thus he found that, while each of Chevalier's doublet
lens, when used singly, presented a "blur" or "coma" o
this coma, instead of being exaggerated by the combination o
these doublets, was much diminished. On the other han
two of Tulley's triplets, each of which performed admi
itself, were used together, the images of all objects not in th
presented a strong blur inwards with an under-correction of co

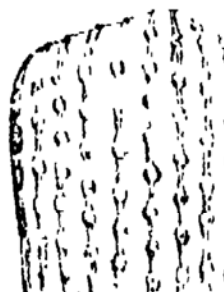
[3] In 1837 Mr Lister gave Mr Ross a projection for an obj
$\frac{1}{4}$ inch focus, in which a triple front was combined with two d
The great superiority of this lens, admirably executed by Mr Ros
him to adopt its plan as the standard one for high powers; and
in general use,—the back lens also being sometimes made as

microscopic objectives that surpassed any then con-
ted on the Continent, while the subsequent adoption
e same principles by French and German opticians,
o by Professor Amici of Florence, soon raised their
tives to a corresponding level.

has proved more advantageous in practice to
the several components of an achromatic objective
ct each others' aberrations than to attempt to render
perfect in itself; and the mode in which this is
nplished will vary with the focus and angular aperture
to each combination. Thus, while a single "telescopic
t" answers very well for the lowest power usually
(4 inches focus), and the same plan may be used
gh at the sacrifice of angular aperture for objectives
inches, 2 inches, and even 1 inch focus, the best per
ance of these powers requires the combination of two
lets. And, while this last system also serves for
tives of $\frac{3}{4}$ inch and $\frac{1}{2}$ inch of low angle, a third com
nt is required for giving to these objectives the
ure that renders them most serviceable, as well as for
gher powers. Instead of combining three achromatic
lets, however, many makers prefer placing in front a
convex of crown, and adding a third lens of crown to
oublet at the back, still using a doublet in the middle,
whole combination thus consisting of six lenses, four
rown and two of flint. Further, Mr Wenham has
n that the whole colour-correction may be effected in
iddle by interposing a double concave of dense flint
een two double-convex lenses of crown, the back lens,
ll as the front, being then a plano-convex of crown,
ng five lenses in all. This plan of construction, though
le to objectives of moderate angular aperture, and
ntageous in regard to comparative simplicity and
my of construction, does not seem so well adapted for
tives to which the largest attainable aperture is to be
, these being usually constructed with a triplet in
, a doublet in the middle, and a triplet at the back, so
consist of eight separate lenses. And the first class
ructors of achromatic objectives in the United States
ly place in front of these, in their highest powers, a
plano-convex of crown, by the addition of which a
er working distance can be obtained. But, as every
addition increases the liability to error from imper-
ons in the centring and grinding of the lenses (as
as loss of light by the partial reflexion of oblique
from their surfaces), it is obvious that the most exact
manship, involving a proportionate costliness, is
red to bring out the full effect of such complex com
tion. And where angular aperture is regarded as the
ty of primary importance it will be usually found
rable to have recourse to objectives constructed on
r the "water" or the "oil" immersion system, to be
ntly described.

e great increase thus attained in the perfection
e corrections of microscopic objectives for both
cical and chromatic aberration of course rendered
ssible to make a corresponding increase in their
lar aperture. The minute scales of the wings of
erflies and other insects were naturally among the
ts much examined; and it was soon perceived that
in lines and other markings became clearly discernible
ese scales with objectives of what was then considered
angle which were utterly undistinguishable with
achromatized microscopes (however high their magnifying
power), and very imperfectly shown under achromatic
tives of small angle. Hence these scales came to be
as "test-objects," for judging of the "definition" and
olving power" of microscopic objectives, the former
erty consisting in the clearness, sharpness, and freedom
false colour of the microscopic images of boundary
lines, and depending on the accuracy with which th
rations are corrected, while the latter term designat
power of separating very closely approximated m
which is now known to be a
"function" of aperture. The
insect scales formerly most valued
for these purposes were those of
the *Morpho menelaus* (fig. 5) and
the similarly lined scales of the
Polyommatus argus (azure blue),
the "battledoor" scales of the
same butterfly (fig. 6), the ribbed
scales of the *Lepisma saccharina*
(sugar louse), and the minute and
peculiarly marked scales of the
Lepidocyrtus curvicollis (fig. 7),
commonly known as the *Podura*.
The writer recollects the time
when the satisfactory "resolution" of the first three of these
tests was considered a sufficient
proof of the go even
high power objective, and when
the *Podura*-markings, if visible at all, could only
distinguished as stria. The further opening
aperture, however enabled these stri
to be resolved into rows of "exclamation marks," and, while there is still
some uncertainty as to the precise
structure of which these markings are
the optical expression, practical opticians are generally agreed that the
Podura scale is very useful as a test
for definition, with even the highest
objectives, though it only
test for a very moderate degree of re
solving power. For the latter purpose
it has been completely superseded by
the closely approximated markings of
the silicified envelop of the
diatoms (which, however, show them
selves in very different aspects according to the conditions under which they are vie
8, 11), and also by lines artificially ruled on gla
Nobert's "test plate," the number
of lines in the nineteen bands of
which is stated by M. Nobert
to range from 1000 to 10,000
to a Paris line, while Dr Royston
Pigott gives the number in an
English inch as 11,529 to the inch
in the first band and 112,590
in the nineteenth. This last
dimension (as will afterwards
appear) approaches the minimum
distance at which such markings
are theoretically separable by any
magnifying power of the microscope.

The enlargement of the angle
of aperture of microscopic objectives and the greater completeness of their corrections, which
were obtained in the first instance by the adoption of Mr
Lister's principles, and were demonstrated by the resolution of
the test-objects then in use, soon rendered sen
imperfection in their performance under certain
stances, which had previously passed unnoticed;



tant discovery was made by Mr Andrew Ross that
y decided difference exists in the precision of the
according as the object is viewed with or without
ring of thin glass, as also according as this cover is
r thick.[1] As this difference increases in proportion
widening of the aperture, it would obviously be a

that standard to the extent of one or two thousan
an inch in either direction, though extremely in
to the performance of objectives whose aperture is
more, scarcely makes itself perceptible in those of
100°. And the same may be said in regard
immersion objectives next to be described, whi
peculiarly suitable to the purposes of minute histo
research.

Immersion System. It was long since pointed
Professor Amici that the introduction of a drop o
between the front surface of the objective and eit
object itself or its covering glass would diminish t
of light resulting from the passage of the rays fr
object or its covering-glass into air, and from air i
front glass of the objective. It was obvious to him
over, that when the rays enter the object-glass from
instead of from air, both its refractive and its dis
action will be so greatly changed as to need an imp
constructive modification to meet the new condition.
modification seems never to have been successfully
by Amici himself; but his idea was taken up by t
eminent Paris opticians, MM. Hartnack and Nache
showed that the application of what is now known
"immersion system" to objectives of short focus an
angular aperture is attended, not merely with the
tages expected by Professor Amici, but with others o
he did not reckon. As the loss of light by the refle
a portion of the incident rays increases with the ob
of their incidence, and as the proportional loss is far
when the oblique rays pass into glass from wate
when they enter it from air, the advantage of i
ing the angular aperture is more fully expe
with "immersion" than with "dry" objectives,
Professor Amici anticipated. But, further, the
sion system allows of a greater working distance b
the objective and the object than can be attained
dry or air objective having the same angular ap
and this increase affords not only a greater freed
manipulation, but also a greater range of "penetr
or "focal depth." Further, the observer is rende
much less dependent upon the exactness of his
correction that it is found that water-immersion obj
of high power and considerable angular aperture, ext
well adapted for the ordinary purposes of scientific
tigation, can be constructed without it,—a small dep
from the standard thickness of covering-glass to whic
objectives are adjusted by the maker having scarce
effect upon the distinctness of the image. It is n
practice of several makers to supply two fronts to obj
of $\frac{1}{10}$ or $\frac{1}{12}$ inch focus, one of them fitting the object
use "dry" (that is, in air), whilst the substitution
other converts it into a water-immersion objective.
in the objectives constructed on Mr Wenham's syst
change in the front glass is needed, all that is necess
making them work as immersion-lenses being a yet
approximation of the front lens to the second combi
which can be made by the screw-collar.

Within the last few years, however, the imm
system has undergone a still further and most imp
development, by the adoption of a method ori
suggested by Mr Wenham (though never carried
him), and independently suggested by Mr Stephen
Professor Abbe of Jena, under whose direction it w
worked out by Zeiss (the very able optician of Jena
has been followed by Powell and Lealand of Lon
well as by several other constructors of achromatic

oth in England and elsewhere, with complete
This method consists in the replacement of the
reviously interposed between the covering-glass and
nt glass of the objective by a liquid having the same
ve and dispersive powers as crown-glass, so that the
uing at any angle from the upper plane surface of
ering-glass shall enter the plane front of the objec-
thout any deflexion from their straight course, and
any sensible loss by reflexion,- even the most
rays that proceed from the object keeping their
n unchanged until they meet the back or convex
of the front lens of the objective. It is obvious
the advantages derivable from the system of water
ion will be still more thoroughly attained by this
of "homogeneous" immersion, provided that a fluid
obtained which meets its requirements. After a
urse of experiments, Professor Abbe found that oil
r wood so nearly corresponds with crown glass, alike
active and in dispersive power, as to serve the
extremely well, except when it is desired to take
advantage of the most divergent or marginal rays,
ennel being then preferable. There are, however,
objections to the use of these essential oils in the
y work of research; and it seems not unlikely that
ion of some one or more saline substances will be
more suitable. In addition to the benefit conferred
water immersion system, and more completely
d with the homogeneous, it may be specially pointed
at, as no correction for the thickness of the covering-
s here required, the microscopist can feel assured
has such a view of his object as only the most per-
rrection of an air-objective can afford. This is a
of no small importance, for while, in looking at a
object, the practised microscopist can so adjust his
ective to the thickness of its covering-glass as to
ut its best performance, he cannot be sure, in regard
unknown object, what appearances it ought to pre-
nd may be led by imperfect cover-correction to an
ous conception of its structure.

s been recently argued that, as the slightest variation in the
ve index of either the immersion fluid or the covering glass,
ge of eye pieces, or the least alteration in the length of the
in a word, any circumstances differing in the slightest degree
hose under which the objective was corrected -must affect
formance of homogeneous-immersion objectives of the highest
hey should still be made adjustable. The truth of this
tion can, no doubt, be proved, not only theoretically, but
ally, -the introduction of the adjustment enabling an experi-
manipulator to attain the highest degree of perfection in the
ion of many mounted objects, which cannot be so well shown
bjectives in fixed settings. But it may well be questioned
r it is likely to do the same service in the hands of an ordi
orking histologist, and whether the scientific investigator will
d it preferable, when using these objectives, to accept what their
has fixed as their point of best performance. The principal
of error in his employment of them lies in the thickness of the
section of the object; for the rays proceeding from its deeper
having to pass through a medium intervening between that
nd the cover-glass, whose refractive and dispersive indices
from those of the glass and immersion-fluid, cannot be
t to so accurate a focus as those proceeding from the plane
iately beneath the cover-glass. The remedy for this, how
seems to lie rather in making the preparation as thin as
le than in the introduction of what is likely, in any but the
kilful and experienced hands, to prove a new source of error
one who has examined muscular fibre, for example, under a
jective of very high power and large aperture, well knows
great an alteration is produced in its aspect by the slightest
in either the focal adjustment or the cover-correction
t is impossible to say with certainty what are the appear
which give the most correct optical expression of its structure.
eing a matter of judgment on the part of each observer, it
obvious that the nearest approach to a correct view will be
ly given by the focal adjustment of the best homogeneous
sion-objectives, in fixed settings, to the plane of the prepara-
mmediately beneath the cover-glass (see *Jour. Roy. Micros.* 1882, pp. 407, 854, 906).

In every particular in which the water-imm
system is superior to the dry, it is itself surpasse
the oil or other homogeneous system, the ant
tions of those by whom it was suggested being thus
realized. But the advantages already spoken of as
able from the use of the "immersion system" are altog
surpassed by that which the theoretical studies of Pro
Abbe have led him to assign to it, and of which h
practically demonstrated its possession. For he has s
(as will be explained below) that the interposition of
water or oil so greatly increases the real "apertu
the objective that immersion-objectives may be constr
having a far greater virtual aperture than even the
retical maximum (180°) of the angular aperture
air-objective.

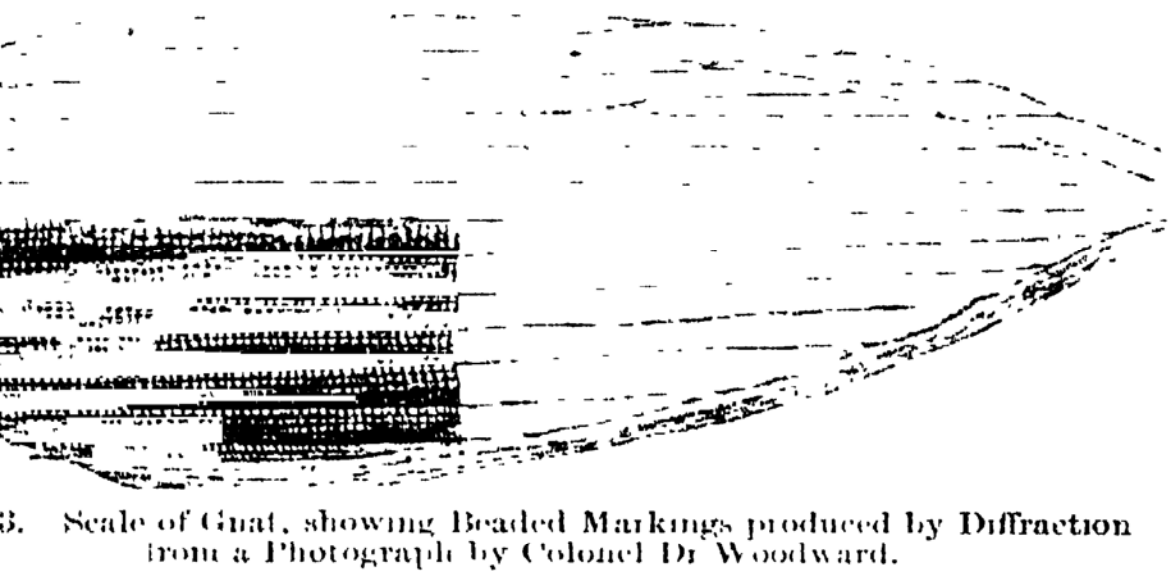
The same eminent physicist, working on the
supplied by the mathematical investigations of Pro
Helmholtz and himself on the undulatory theory of
has further established an entirely new doctrine in
to the production of highly magnified representatio
closely approximated markings. All that has hi
been said of the formation of images by the comp
microscope relates to such as are produced, in accor
with the laws of refraction, by the alteration in dir
which the light rays undergo in their passage throu
lenses interposed between the object and the eye.
dioptric images, when formed by lenses free from sp
and chromatic aberration, are geometrically correct pi
truly representing the appearances which the objects
selves would present were they enlarged to the sam
and viewed under similar illumination. And we
justified, therefore, in drawing from such micr
images the same conclusions in regard to the objec
picture as we should draw from the direct vision of
objects having the same dimensions. The principal so
error in such interpretations arises out of the "interfe
to which the rays of light are subjected along the e
the minute objects through which they pass, or alo
such lines or margins in their inner part as are suffi
opaque to throw a definite shadow. For every
shadow must be bordered, more or less obviously, b
ference or diffraction spectra; and thus the ima
strongly-lined objects with very transparent interv
spaces may be so troubled or confused by these "diffr
spectra" as to render it very doubtful what interpr
is to be put upon their appearances.

A good example of this kind is afforded by the scale
gnat or mosquito, which are composed of a very delicate
membrane, strengthened by longitudinal ribs on both side
of the opposite sides uniting at the broad end of the scal
they generally terminate as bristle-shaped appendages bey
intermediate membrane. These are crossed by fine marking
are probably ridge like corrugations of the membrane, com
both sides of the scale. Between each pair of longitudina
there may be seen, under certain adjustments of focus and
nation, three uniform parallel rows of beads, which ha
supposed to represent a true structure in the membrane.
Woodward (colonel in the United States army), however, it
shown that this beaded appearance is merely the result of the
ferences" produced by the longitudinal and transverse lin
scale. For the longitudinal diffraction-lines are clearly se
in the microscopic image and in photographs (fig. 13), to ex
empty space beyond the contour of the scales, almost as f
ends of the bristles in which the parallel ribs termina
they vary in number with the varying obliquity of illumin
that in the same scale two, three, four, or even five rows
can be seen, and photographed at pleasure, in every in
space.[1]

Every microscopist who has worked much wi
powers is well aware of the difficulty of disting
between real and spectral markings, a difficulty wh
only be overcome by training and experience. It

[1] *Monthly Micros. Jour.*, vol. xv. (1876), p. 253.

er, to have been now fully ascertained by Pro- Abbe that it is only through such diffraction-spectra he microscope can make us acquainted with the est structural features of objects, since, according calculations of Professor Helmholtz and himself on the constants of the undulatory theory), no nt of magnifying power can separate dioptrically two apertures, or markings of any kind, not more than of an inch apart. The visual differentiation or lution" of lines or other markings whose distance lies



3. Scale of Gnat, showing Beaded Markings produced by Diffraction from a Photograph by Colonel Dr Woodward.

that limit is entirely the result of "interference," jective receiving and transmitting, not only dioptric out the inflected rays whose course has been altered r passage through the object by the peculiar disposi- f its particles, and combining these rays into a series raction-spectra, the number and relative position of bear a relation to the structural arrangement on their production depends. If the objective be per- corrected, and all the diffraction-spectra he within l, these will be recombined by the eye-piece so as to secondary or "diffraction" image, lying in the same with the dioptric image, and coinciding with it, while up its outlines by supplying intermediate details. here the markings (of whatever nature) are so closely imated as to produce a wide dispersion of the inter- spectra, only a part of them may fall within the of the objective and the recombination of these by ye-piece may produce a diffraction-image diffe or less completely (perhaps even totally) from the ucture; while, if they should he entirely outside ld of the objective, no secondary or diffraction image produced. And thus, while the general form of n object as a diatom-valve may be correctly given in tric image, its surface may appear quite unmarked an objective of small aperture, however great its fying power, though covered with regularly disposed ngs when seen through an objective of wider aperture erhaps only half the magnifying power.

s obvious, however, that, while the dioptric image sents the actual object, the diffraction-image thus l by the reunion of a portion of the interference s only an optical expression of the result of their l recombination, which may represent something ly different from the real structure. For it has been l experimentally, by placing finely-ruled gratings in osition of object, and by limiting the apertures of ives by diaphragms with variously disposed perfora that the same arrangement of lines shall be presented e eye by differently lined surfaces, and different gements by similarly lined surfaces, according to the ers and relative positions of the reunited spectra. it is clear that there must be an essential difference aracter and trustworthiness between the images ically formed of the general outlines and larger of microscopic objects and those representations of iner details which are given by the recombination of their diffraction-spectra,[1] and that the confidence placed in the latter class of representations will be in proportion to the completeness of the recombina the separated interference-spectra, which, again, proportional (accurate correction of the aberrations assumed) to the aperture of the objective.[2]

The combined advance of scientific theory a practical skill in the application of it have now b up the compound achromatic microscope to an optic fection that renders it capable of actually doing everything of which, in the present state of theory, it can be regarded as capable. The res of Nobert's nineteenth band, having 112,59 to an inch, which was long regarded as the microscopists, is now found so easy as to leav room for doubt that, if a new test were obt having the *minimum visibile* of 118,000 lines inch, an oil-immersion objective would be fo resolve it. But the experience of the past m evident that, as no limit can be set to the a of optical theory, results yet more remarkable still expected to arise, every such advance being to account by the practical skill which experie now enabled the best constructors of achrom jectives to attain.[3]

The progressive improvements thus effected in the cons of microscopic objectives have been accompanied by other i ments, alike in the optical and in the mechanical arrangen which the best performance of these objectives can be secu it will be desirable now to describe in succession the most a forms of the eye piece, the objective, and the illuminating a respectively, and then those of the instrument as a whole ng out the special adaptiveness of each to the requiren different classes of scientific investigators.

Eye-Pieces.

It very early became obvious to those who were en the achromatization of microscopic objectives that th performance was obtained when the image given by th further enlarged by the eye-piece known as the Huyge having been devised by Huygens for his telescopes. It of two plano-convex lenses (EE and FF, fig. 4), with th sides towards the eye; these are placed at a distance equa the sum of their focal lengths,—or, to speak with more p at half the sum of the focal length of the eye-glass, and of tance from the field-glass at which an image of the obj would be formed by it. A "stop" or diaphragm BB placed between the two lenses, in the visual focus of the e which is, of course, the position wherein the image of th will be formed by the rays brought into convergence passage through the field-glass. Huygens devised this ment merely to diminish the spherical aberration; but it w quently shown by Boscovich that the chromatic dispersion in great part corrected by it. Since the introduction of ach object-glasses for compound microscopes, it has been furthe that nearly all error may be avoided by a slight over-corr that the blue and red rays may be caused to e eye in a parallel direction (though not actually coincide thus to produce a colourless image. Thus let N, M, N (fig. 1 sent the two extreme rays of three pencils, which with field-glass would form a blue image convex to the eye-glas and a red one at RR; then, by the intervention of the fie a blue image concave to the eye-glass is formed at B'B', a

[1] Thus it is still a moot point whether the microscopic ances seen in the siliceous valves of diatoms (figs. 8–11) optical representations of elevations, depressions, or perfora of internal molecular arrangements not involving any ineq surface.

[2] This doctrine was first fully developed by Professor Abb *Archiv für Microsk. Anatomie*, vol. ix. (1874), and is more pounded in his subsequent contributions to *Jour. Roy. Mic* See also the papers of Mr Stephenson and Mr Crisp in that and in the preceding *Monthly Microscopical Journal*.

[3] Any good workman can now make by the dozen such sma ⅓ inch objectives as Mr A. Ross produced with much pains an fifty years ago. It was not until 1844 that, with the ho emulation of surpassing what Professor Amici had then accon he produced a $\frac{1}{10}$ inch of 135°, which, by taking advantage very heavy flint-glass he had, he afterwards increased to 170°

R'R'. As the focus of the eye-glass is shorter for blue ray
red rays by just the difference in the place of these images
ys, after refraction by it, enter the eye in a parallel direction
duce a picture free from false colour. If the object-glas
en rendered perfectly
atic, the blue rays,
passing through the
ass, would have been
to a focus at *b*, and
at *r*; so that an error
be produced, which
have been increased in-
f being corrected by the
ss. Another advantage
well-constructed Huy-
eye-piece is that the
produced by the meet-

or more Huygenian eye-
of different magnify-
vers, known as A, B, C,
usually supplied with
ound microscope. The utility of the higher powers wi
depend upon the excellence of the objectives; for, when a
natic combination of small aperture which is sufficiently we
ed to perform very tolerably with a "low" or "shallow
ce is used with an eye-piece of higher magnifying power (con
spoken of as a "deeper" one), the image may lose more i
ness and in definition than is gained by its amplification, whi
age given by an objective of large angular aperture and ver
correction shall sustain so little loss of light or of definitio
eep eye-piecing" that the increase of magnifying power sha
ost clear gain. Hence the modes in which different objective
same power, whose performance with shallow eye pieces
the same, are respectively affected by deep eye pieces allor
test of their respective merits, since any defect in the corre
sure to be brought out by the higher amplification of th
while a deficiency of aperture is manifested by the want
The working microscopist will generally find the A ey
ost suitable, B being occasionally employed when a greate
is required to separate details, whilst C and others still deep
ful for the purpose of testing the goodness of objectives,
cial investigations requiring the highest amplification wit
ves of the finest quality. But he can commit no great
han habitually to use deep eye-pieces for the purposes
fic research, especially when (as in the study of livin
) long-continued and unintermitted observation is necessar
e visual strain thus occasioned is exactly like that resultin

viewing large flat objects, such as transverse sections of woo
Echinus spines, under low magnifying powers, the eye-pie
as Kellner's may be employed with advantage. In th
uction the field-glass, which is a double convex lens,
in the focus of the eye-glass, without the interposition of
agm; and the eye-glass is an achromatic combination of
concave of flint with a double-convex of crown, which
y under-corrected, so as to neutralize the over-correctio
to the objectives for use with Huygenian eye pieces.
ll-illuminated field of as much as 14 inches in diamet
nus be obtained with very little loss of light; but, on t
nand, there is a certain impairment of defining power, whi
s the Kellner eye-piece unsuitable for objects presenti
e structural details; and it is an additional objection th
allest speck or smear upon the surface of the field-glass
so unpleasantly obvious that the most careful cleansing
urface is required every time that this eye-piece is use
it is better fitted for the occasional display of objects of t
ter already specified than for the ordinary wants of t
ng microscopist.

d eye-pieces, consisting of cylinders of glass with convex en
metimes used in place of the Huygenian, when high magn
power is required for testing the performance of objectiv
ower surface, which has the lesser convexity, serves as a

FIG. 14.—Section of Huygenian Eye Piece, adapted to Over-Corrected Microscopic Objectives.

[1] The reader may be referred to Mr Varley's investigation of the properties of the Huygenian eye-piece in the fifty-first volume of the *Transactions of the Society of Arts*; and to the article "Microscope," by Mr Ross, in the *Penny Cyclopædia*, reprinted, with additions, in the *English Cyclopædia*.

field-glass, while the image formed by this is magnified
highly convex upper surface to which the eye is applie
advantage derivable from this construction lying in the abol
the plane surfaces of the two lenses of the ordinary eye-piec

A "positive" or Ramsden's eye-piece—in which the fiel
whose convex side is turned upwards, is placed so much ne
eye-glass that the image formed by the objective lies below
of above it—was formerly used for the purpose of microme
divided glass being fitted in the exact plane occupied by the
so that its scale and that image are both magnified together
lenses interposed between them and the eye. The same en
ever, may be so readily attained with the Huygenian e
that no essential advantage is gained by the use of that of R
the field of which is distinct only in its centre.

Objectives.

It has been seen that one of the principal points in t
struction of microscopic objectives to which the attention
makers has been constantly directed has been the enla
of their "aperture,"—this term being understood to me
their absolute opening as expressed by linear measure, b
capacity for receiving and bringing to a remote conjugate f
rays diverging from the several points of a near object. T
ture of an objective has been usually estimated by its "
aperture,"—that is, by the degree of divergence of the most
rays proceeding from the axial point of the object to the m
the objective (fig. 15) which take part in the formation
image. It is pointed out, however, by Professor Abbe that, in the case of single lenses used as objectives, their apertures are really proportional, not to their respective angles of aperture, but to the ratio between the actual diameter or clear opening of each to its focal distance, a ratio which is simply expressed by the sine of its semiangle. And in the case of combinations of lenses it can be demonstrated mathematically that their respective apertures are determinable—other conditions being the same—by the ratio of the diameters of their back lenses, so far as these are really utilized, to their respective focal lengths, this ratio being expressed, as before, by the sine of the semiangle of aperture ($\sin u$). The difference between these two modes of comparison readily made obvious by reference to the theoretical max 180°, which is attained by opening out the boundaries of t *abe* (fig. 15) until they come into the same straight line, th the semiangle (90°) then becoming unity. For, while an having an angle of 60° would count by comparison of a having only one-third of the theoretical maximum, its real would be half that maximum since the sine of its s (30°) = ½. And, as the sines of angles beyond 60° incre slowly, an objective of 120° angle will have as much as 87 of the theoretical maximum of aperture, although its angl two-thirds, or 66·6 per cent., of 180°. It hence becomes that little is really gained in real aperture by the openin the angle of microscopic objectives to its greatest practica (which may be taken as 170°), while such extension—unattended with any loss either of definition or of colour-c—necessarily involves a great reduction alike in the work tance and in the focal depth or penetration of the comb as will be presently explained.

FIG. 15. Section of Ac Object Glass, comp three pairs of (th crown) lenses. *abe* is of aperture.

Numerical Aperture.—It has now been demonstrated by Abbe that, independently of the advantages already spe derivable from the application of the immersion system to of short focus and wide aperture, the real aperture of a sion objective is considerably greater than that of a d objective of the same angle, the comparative apertures tives working through different media being in the ratio of two factors, viz., the sines of their respective se of aperture and the refractive indices of the "immersion It is the product of these ($n \sin u$) that gives what is to Professor Abbe the "numerical aperture," which serves, as the only true standard of comparison, not only betwe air and water or oil immersion lenses, but also between n lenses adapted to work respectively with water, oil or a interposed fluid. That the angle of aperture expresse same number of degrees must correspond with very differe ing apertures in dry, water immersion, and oil or hom immersion objectives becomes evident when we consi

[2] These eye-pieces are much in vogue in the United States, where the of extremely short focal—even to ⅛ inch.

when divergent pencils of rays pass from one medium other of higher refractive index. For such divergent proceeding from air into water or oil, will be closed or compressed; so that the rays which, when an object ited in air, spread out over the whole hemisphere then omparatively narrow pencils, and can thus be utilized mmersion objective of smaller aperture than is required in bjective to admit the most diverging rays of air-pencils. vs, therefore, that a given angle in a water or oil immersion e represents a much larger aperture than does the same n an air objective; and thus it comes to pass that by out the angle of immersion objectives they may be made ve and utilize rays of much greater divergence than can enter dry objectives of even maximum aperture.

following table, abridged from that given by Professor Abbe y 0·02 of numerical aperture from 0·50 up to the maximum brings this contrast into clear view:—

Numerical Aperture Table.

Angle of Aperture (= 2u)			Illuminating Power (a^2)	Theoretical Resolving Power, in Lines to an Inch (λ = 0·5269 μ = line F).	Penetrating Power $\left(\frac{1}{a}\right)$

60 0	44 10	38 24	·250	48,200	2·000

taking as a standard of comparison a dry objective of ximum theoretical angle of 180°, whose numerical aperthe sine of 90°, or 1·00, we find this standard equalled ter immersion objective whose angle of aperture is no more °, and by an oil or homogeneous immersion objective 82°, the numerical apertures of these, obtained by multi the sines of their respective semiangles by the refractive f water or of oil, being 1·00 in each case. Each, the re- l have as great a power of receiving and utilizing divergent ny dry objective can even theoretically possess.

as the actual angle of either a water or an oil immersion e can be opened out to the same extent as that of an air ob ective, it follows that the aperture of the former can be ted far beyond even the theoretical maximum of the latter. he numerical aperture of a water-immersion lens of the m angle of 180° is 1·33, or one-third greater than that ir-lens of the same angle; and this aperture would be y an oil-immersion objective of only 122°. Again, the l aperture of an oil immersion objective having the theo maximum angle of 180° would be 1·52, or more than one ater than that of an air-lens of the same angle. And the al apertures corresponding to angles of 170°, which have tually attained in both cases, fall very little short of the ons just given.

gain, an oil immersion objective whose angle of aperture is has as high a numerical aperture (0·76) as a water- on objective of 69½°, or as a dry objective of 99°; and a dry e of 140° has no greater a numerical aperture (0·94) than immersion of 90° or an oil immersion of 76½°.

important doctrine may be best made practically intelligible omparison of the relative diameters of the back lenses of th those of water and oil immersion objectives of the ower, from an "air angle" of 60° to an "oil angle" of these diameters expressing, in each case, the opening between treme pencil forming rays at their issue from the posterior of the combination, to meet in its conjugate focus for the ion of the image, the relation of which opening in each case focal length of the combination is the real measure of its e (fig. 16). Thus the dry objective of 60° angle (5 in fig. 16) air angle represented by $\sin u = \frac{1}{2} = 0{\cdot}50$ numerical aperture. y objective of 97° (4) has its air angle represented by $\sin u =$ 5 numerical aperture. And the dry objective having the tical) angle of 180° (3) has its air-angle represented by $\sin u$ numerical aperture, this corresponding to 96° water- and 82° oil-angle. But the water-immersion lens having coretical) angle of 180° (2) has its water-angle represented $nu = 1{\cdot}33$ numerical aperture. And the oil-immersion lens having the (theoretical) angle of 180° (1) has its oi represented by $n \sin u = 1{\cdot}52$ "numerical aperture."[1] theoretical apertures for water and oil immersion lenses havin found as nearly attainable in practice as the theoretical max for dry objectives, such lenses can utilize rays from mounted in balsam or other dense media, which are entirely lost for the image (since they do not exist physically) when the same object is in air or is observed through a film of air. And this loss cannot be compensated by an increase of illumination; because the rays which are lost are different rays physically from those obtained by any illumination, however intense, through an aeriform medium.

It is by increasing the number of diffraction-spectra that the additional rays thus received by objectives of great numerical aperture impart to them an increased resolving power for lined and dotted objects,—the truth of the image formed by the recombination of these spectra being (as already shown) essentially dependent on the number of them that the objective may be capable of receiving.

But whilst the resolving power of microscopic objectives increases in the ratio of their respective numerical apertures, and whilst their illuminating power (dependent upon the quantity of light that passes through them) increases with the square of the numerical aperture, the case is reversed with another most important quality,—that of penetration or focal depth; for this diminishes as the numerical aperture increases, until nothing but what is precisely in the focal plane can be even discerned with objectives possessed of the highest resolving power. Thus, the penetrating power of an objective of 60° air-angle being expressed as 2·000, an extension of that angle to 76½° reduces it to 1·613, an extension to 89° reduces it to 1·429, and an extension to 99° reduces it to 1·316; further extension to 118½° reduces it to while an objective whose air angle is 140° has a penetrating of only 1·064. So, again, the oil immersion objective which numerical aperture of 1·00 corresponding to the theoretic angle of 180° has a penetrating power of 1·000; this is b down to ·752 when its angle is so increased as to make its nu aperture 1·33, equalling the theoretical maximum of a immersion objective, and is ·658 at the theoretical maximum of an oil-objective.

Fig. 16.—Relati meters of Back of Air, Wate Oil Immersion tives.

Hence it is clear that, as some of the qualities to be sou microscopic objectives are absolutely incompatible, a prefer to be accorded to objectives of greatest resolving power bu little penetration, or to those of moderate resolving pow great penetration, according to the uses to which they are applied; and some general principles will now be laid do regard to this matter, based alike on science and experience.

In the first place, a marked distinction is to be drawn b those objectives of low or moderate power which are to be v dioptrically and those of high power which are to be work fractively. The objects on which the former are to be for th part used are either minute transparent bodies having solid which the observer should be able to take in as wholes (as case of *Polycystina*, the larger diatoms, *Infusoria*, &c.); or parent sections, dissections, or injections, whose parts different planes, the general relations of which he desires to while reserving their details for more special scrutiny; or objects, whose structure can only be apprehended fro examination of their surfaces, when the inequalities of tho faces are seen in their relations to each other. In all thes it is desirable that microscopic vision should resemble or vision as much as possible. If the eye were so constructed enable us to discern only those parts of an object that l cisely in the plane to which we focus it, our visual concept the forms and relations of these parts, and consequently object as a whole, would in general be very inadequate, an erroneous. It is because, while focussing our eye successiv the several planes of the object, we can see the relation of what is nearer and more remote that we can readily acc visual conception of its shape as a whole, and that unmist perception of solid form which is given by the combination two dissimilar perspectives of near objects in binocular

[1] The dotted circles in the interior of 1 and 2, of the same diameter as the excess in the diameters of the back lenses of the water and oil ob over that of the dry at their respective theoretical limits.

could not possibly be formed if our vision were strictly
o the exact plane for which our eyes are focussed.
it is obvious that, in the case of objectives of low and
amplification, focal depth or penetration is a quality
want of which no other excellence can compensate,—
ning-out of their apertures being only advantageous in
s it does not seriously interfere with their penetrating
It is, no doubt, quite possible to construct a 1 inch
with an aperture so large that, when the requisite ampli-
has been gained by deep eye-piecing, it shall resolve
d "tests" ordinarily used for a $\frac{1}{4}$, or to construct an
of $\frac{4}{10}$ inch focus which shall in like manner do the
work of a $\frac{1}{8}$. But, as such objectives are thereby spoiled
r own proper work, the loss to the microscopist is but
ompensated by his ability to resolve with them, under such
-pieces as cannot be habitually used without serious risk to
sight, the lined and dotted tests which can be much better
nder objectives of shorter focus and wider aperture, with eye-
low amplification. For, whilst deep eye-pieces cannot be
ly employed for continuous observation, without putting
upon the eyes resembling that which results from the
use of a magnifying glass, even the very highest objectives
used continuously for long periods in combination with
eye pieces, with scarcely any fatigue, and therefore (it is
) without sensible injury.[1]

timating the goodness of a microscopic objective, five
qualities have to be separately considered:—(1) its work-
nce, or the actual interval between its front lens and the
which it is focussed; (2) its penetrating power, or focal
3) the flatness of its field; (4) its definition, or power of
distinct image of all well-marked features of an object,
cially of their boundary lines; and (5) its resolving power,
h it separates closely approximated lines, dots, or strie.

e "working distance" of an objective has no fixed relation
cal length,—the latter being estimated by its equality in
ith a single lens of given radius of curvature (such as
$\frac{1}{2}$ inch, $\frac{1}{10}$ inch, &c.), while the former varies with
le in which the combination is constructed and with the
given to it. For low and moderate powers, ranging up to
focus, good working distance is especially important,
ecause it is closely related to penetrating power, and also
it facilitates the use of side-illumination for opaque objects.
such objectives of high power as are to be used, not for the
n of lined or dotted tests, but for the observation of living
ing objects of extreme minuteness, good working distance
s important, on account of its relation to focal depth. In
of those objectives, on the other hand, in which resolving
made the first consideration, it is only needful that the
distance shall be such as to permit the interposition of a
ss cover; and this, although necessarily diminished with
ning of the aperture, can be always obtained by the adoption
mmersion system.

e "penetrating power" or "focal depth" of an objective
defined as consisting in the vertical range through which
s of an object not precisely in the focal plane may be seen
fficient distinctness to enable their relations with what lies
n that plane to be clearly traced out,—just as would be done
nary vision if the object were itself enlarged to the dimen
its microscopic image. The close relation between this
and the preceding becomes obvious when it is considered
longer the working distance of an objective the less will
inctness of the image it forms be affected by any given
n (say the $\frac{1}{1000}$ of an inch) in its focal adjustment. Con-
y, of two objectives having the same magnifying power but
working distances, that one will have the most focal depth
orking distance is the greater. On the other hand, as the
ing power of an objective is reduced in direct accordance
increase of its numerical aperture, it must be sacrificed
r the highest resolving power is to be attained. Hence,
dly remarked, this attribute will be very differently valued
rent observers, according to the work on which they are
vely engaged. For the general purposes of biological
, not only with low or moderate (for the reasons already
but also with high powers, a considerable amount of
pth is essential. It is impossible, for example, to follow
orily the movements of an *Amœba*, or to study the
is" in the cell of a *Vallisneria*, or to trace the distribution
rve-thread, with an objective in which focal depth is so
ly sacrificed to aperture that nothing can be discerned
at is precisely in the focal plane, since, instead of passing
nally from one focal plane to another, as the observer can
an objective of good penetration, he can only get a succes-
"dissolving views," with an interval of "chaos" between
each pair. When, on the other hand, it is desired to scrutini
the greatest precision such minute details as are presented
and the same focal plane (as, for example, those of the t
possible film of tissue spread out between a glass slide and it
ing glass), the microscopist will prefer an objective in whic
depth is subordinated to aperture, for the sake of the re
power which he can thus command. And it will often hap
biological research that it is advantageous thus to bring ob
of the latter class to bear upon objects which could not ha
detected in the first instance save by objectives of much
resolving power but greater focal depth.

3. The "flatness of the field" afforded by the objecti
condition of great importance to the advantageous use of th
scope, since the extent of the area clearly seen at one time
cally depends upon it. Many objectives are so constructe
even when the object is perfectly flat, the foci of the cent
peripheral parts of the field are so different that, when the
ment is made for one, the other is more or less indistinct.
when the central part of the area is in focus, no more info
is gained respecting the peripheral than if the latter had be
gether stopped out. With a really good objective, not only
the image be distinct over the whole field at once, but the n
portion should be as free from colour as the central. As in
tion in this respect is often masked by the contraction
aperture of the diaphragm in the eye piece, the relative m
two objectives, as regards flatness of field, should always be
under an eye piece giving a large aperture.

4. The "defining power" of an objective, which depend
the completeness of its corrections for spherical and for ch
aberration, and upon the accurate centring of its component
is an attribute essential to its satisfactory performance, whate
be its other qualities, its importance in scientific researc
such that no superiority in resolving power can compensate
want of it, and, though it is possible to obtain perfect correc
spherical aberration up to the highest practicable limit of an
the difficulty of securing it increases rapidly with the augme
of aperture, the want of it being made perceptible, especial
deep eye-pieces are put on, by the blurring of clearly-mark
or edges, and by general "fog." Perfect colour correction
other hand, is not possible for dry lenses of the widest a
account of the irrationality of the secondary spectrum, b
may be neutralized by the use of the immersion system. As
stated, what has to be aimed at in the construction of mic
objectives is not absolute colour correction, but a slight d
over-correction, which, by compensating the chromatic di
of the Huygenian eye piece, shall produce an image free fr
colour. As this can be secured far more easily in the cons
of objectives of moderate than in those of very wide apert
cost of the former is proportionally small, an additional
